Case 5. *Scirrhus of the Prostate Gland: Suppression of Urine; Death: Necropsy.*—W. S——, aged sixty-nine, was admitted with hæmaturia. He was remarkably hale and active for his age, with plenty of colour, and stated that he had always been a very sober and healthy man. His father and mother had both died at a very advanced age. Six or seven months ago he noticed that his water scalded him and was tinged with blood. On admission he complained of pain at the end of the penis and in the perineum, especially when he had his bowels moved. Riding and jolting had not been noticed to increase the pain, which was very severe, however, during micturition. The stream of urine never stopped suddenly. Never passed any gravel, but occasionally clots. Never remembers any matter or slime coming away from him. He stated that he had got much thinner and weaker lately. Examination with the sound yielded no results, nor did microscopical examination of the urine. By the rectum the prostate was detected to be increased in size, and was evidently very tender. For some time he was treated with astringents, and enjoined rest in bed; he apparently improved, till one day he found he could not pass any urine. A catheter was passed, but only a few drops came away; this state of things happened each day; percussion and palpation, as well as sounding the bladder, showed that it was always more or less empty. However, he gradually got weaker; and though the temperature was normal and the pulse slightly accelerated, he only complained of thirst, and protruded a dry brown tongue. He had no uræmic symptoms, so-called, no twitchings, delusions, or coma, and was quite sensible up to his death, which seemed to occur simply from asthenia. At the post-mortem examination the bladder was found empty, with thickened walls, but no pouches or evidences of cystitis. The ureters were slightly dilated; the kidneys large and pale, but otherwise healthy; the prostate was enlarged to three or four times its usual size, the growth, however, not interfering with the patency of the urethra. On section it presented unmistakable appearances of new growth, being firm in parts, fibrous, and of a yellowish-white colour. There was no ulceration of the mucous membrane. Microscopically it presented the arrangement of a scirrhous carcinoma.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Tumour of Brain.—Malignant Disease of Bones in a Child.—Sarcoma of Lung and Brain.—Primary Carcinoma of Liver.—Hypertrophied Callus of Tibia and Fibula.—Chronic Cerebro-spinal Meningitis.—Actinomycosis.—Typhoid Fever in Animals.

THE last meeting but one of the present session of this Society took place on Tuesday last, Dr. H. Charlton Bastian, F.R.S., Vice-President, in the chair. The proceedings were of a very interesting character, and good discussions followed the reading of most of the papers. The specimens of actinomycosis showed by Mr. Shattock prove that the disease, though but recently recognised, is certainly not new, seeing that the specimens exhibited were at least a quarter of a century old. The specimen of hypertrophied callus shown by Mr. Bilton Pollard was remarked upon as one of an exceedingly rare kind, and on the motion of Mr. Butlin the specimen was referred to the Morbid Growths Committee for special report.

Dr. CHARLEWOOD TURNER showed a Cerebral Tumour, situate in the fourth ventricle, with a secondary deposit on the posterior surface of the cord, and with lesions of the posterior columns of the cord. The specimen was taken from a girl aged fifteen, who had had symptoms of cerebral tumour for nine months; amaurosis had been noted for two months; vomiting, headache, and pain in the left leg and side were present, and also double optic neuritis. The pupils were widely dilated, but active. There was slight paresis of the left side, but no loss of sensation. The deep reflexes were absent. The superficial reflexes were active. The intellect was unaffected. Paralysis of the left side of the face, followed by an epileptiform attack, ushered in death. A soft sarcomatous growth was found filling up the fourth ventricle, from the walls of which it appeared to have grown, invading the cerebellum and medulla oblongata. Microscopical examination showed much exudation in the posterior columns of the cord. The greater liability of the posterior surface of the cord to be affected with new growths was commented on. The limitation of the spinal lesion to the posterior columns in this case, and the occurrence of early sclerosis of the same columns, were regarded as illustrating the especial liability of these columns of the cord to be the seat of pathological lesions. This afforded an explanation of the frequency of locomotor ataxy as compared with the symptoms referable to primary lesion of other tracts of the cord. The occurrence of cases where the characteristic symptoms of locomotor ataxy are independent of spinal lesion is not inconsistent with the general conclusions from an investigation of thirty years. They prove that these symptoms are not essentially spinal. Symptoms due to lesion of centripetal fibres of the posterior columns result most frequently from interference at the least protected part. There were no facts to show that there is a greater liability for this to occur in the brain, and no evidence of a cerebral lesion in cases of ataxy in general to which the posterior sclerosis could be regarded as secondary.

Dr. NORMAN MOORE exhibited a specimen of Sarcoma of Bones and Viscera in an Infant. The specimens were taken from a boy aged one year and a half, who died in St. Bartholomew's Hospital in one of Dr. Gee's wards. The whole anterior part and most of the base of the skull were infiltrated with huge masses of a tough reddish new growth, which microscopic sections showed to be a round-celled sarcoma. Many other bones were infiltrated. The ten upper left ribs and nine lower right ribs, the whole pelvis, and both femora were infiltrated, and had upon them many bosses of the sarcoma. All the lumbar and cervical glands, the right lobe of the liver, and the right suprarenal body contained masses of the new growth. The case began with pain in the right hip in October, 1884. In December a swelling was noticed over the eye. This was rapidly succeeded by swellings on other parts of the skull. Both eyes were extremely depressed, and the corneæ sloughed away. The growth increased very fast, and the child died on March 3rd, 1885.

Dr. DYCE DUCKWORTH showed specimens of Sarcoma of the Lung and Brain. The case was that of a man aged fifty-two, who was admitted into St. Bartholomew's Hospital in February, 1885. At Christmas last a left hemiplegia developed after an apoplectiform attack. The early symptoms of the lung disease were cough with copious expectoration. There was impaired expansion of the right side of the chest, with dulness over the lower half of the right side, where the vocal fremitus was absent, and the breathing was very weak. Weakness, pain in the chest, and cough, with hæmoptysis, were the symptoms prior to admission. There was slight fever. Death followed eight days after admission into the hospital. In the corpus striatum of the right side was a pinkish velvety mass about the size of a hazel nut, and many similar nodules were found in the roof of the lateral ventricles and elsewhere. A new growth penetrated the right lung, apparently commencing at the root of the organ; the growth followed the course of the bronchi, but did not find its way through the mucous membrane of the tubes, and remained entirely outside the bronchi. There were about six nodules in the liver and one in the pancreas. The growth was a round-celled sarcoma. He had not found any similar case on record in the Society's Transactions.—Dr. CHARLTON BASTIAN asked what was the condition of the temperature.—Dr. NORMAN MOORE said that the temperature chart showed a general rise in the evening to about 101° F.; occasionally the temperature was 103°. He thought that Dr. Duckworth's case was a most interesting one.—Dr. ORMEROD spoke of the means of distinguishing between the hemiplegia resulting from a tumour and that resulting from vascular disease; if optic neuritis were present, then a tumour might be diagnosed.—Dr. DYCE DUCKWORTH said that the case had not been diagnosed during life. The eyes had not been examined.

Mr. PAUL showed a group of specimens of Primary Tumours of the Liver. These specimens represented good types of the different varieties of epithelial new growths of the liver. The first specimen was taken from a woman aged forty-four; there was a bright-green-coloured nodule, encapsuled and attached to a large branch of the portal canal in the centre of the liver. In the midst of the growth was some inspissated material of a green colour. This tumour was an innocent growth of glandular type. The remainder of the liver was cirrhotic in character. The second specimen was removed from a woman aged fifty who died of pleuritic effusion. The liver was in a state of red atrophy, with fatty infiltration. Several white nodules, not encapsuled nor differentiated from the surrounding tissue, were composed entirely of liver tissue. The cells had a trabecular arrangement, and they had a luxuriant growth, and the capillaries were not largely dilated, as they were in the remainder of the atrophied liver. The next specimen was one of primary carcinoma of the liver, which had also a green colour. It was removed from the body of a Scotchman aged sixty-nine; there was no emaciation. Malaise followed by jaundice and ascites, with rapid death from exhaustion, were the chief clinical features. The growth had spread into the portal vein, and the liver weighed 110 ounces, and was very large. The tumour was soft and diffluent, and of a bright-green colour. There were no secondary growths. The dark-green inspissated material was apparently secreted by the cells of the carcinoma. The hepatic character of the cells was commented on. The fourth case was one of scirrhus and cirrhosis of the liver. The fifth case was that of a woman aged forty-eight, who had had jaundice and ascites with hæmorrhage into the peritoneum. The new growth was of a green and yellow colour, and extended into the portal vein. The cells were more uniform and more strikingly hepatic in nature than those of the previous specimen. There was evidence of a direct conversion of the hepatic cells into carcinoma. The sixth specimen was one of cirrhosis and a soft form of carcinoma, which infiltrated the organ and the portal vein. The liver weighed sixty-six ounces, and the tumour was of a bright-yellow colour, probably from rapid fatty degeneration; it was an alveolar carcinoma. The last case was one in which rapid emaciation took place, and the disease lasted three months; the portal vein was distended with carcinoma, and in this specimen also a rapid fatty degeneration had taken place. The first two specimens were examples of growths of an innocent character. The acinous and tubular varieties were illustrated. The other growths were examples of the acinous form of carcinoma; specimens of the tubular form of carcinoma had been brought before the Society by Drs. Mahomed, Greenfield, Pye-Smith, and others.—Dr. C. TURNER asked whether the first two specimens might not be regarded as examples of local hypertrophy of the liver, such as was met with in the suprarenal capsules and in the thyroid body.—Mr. PAUL thought it difficult to draw a hard-and-fast line between local hypertrophy and adenoma.—Mr. S. G. SHATTOCK had seen a specimen the exact counterpart of the third specimen; it had a curious pigmented appearance, which Dr. Bernays found to be due to biliary constituents. He suggested that the presence of such pigment proved that the growth had originated in the hepatic cells, and might thus serve to distinguish it from growths originating in bile-ducts or mucous follicles.—Mr. PAUL agreed with this suggestion.

Mr. BILTON POLLARD showed a specimen of Hypertrophied Callus of Tibia and Fibula, removed by amputation from a female child aged five years, who was a patient in University College Hospital, under the care of Mr. Marcus Beck. The child had a fall which injured the affected leg at the age of one year. A year and a half later a painless swelling was noticed at the middle of the leg. The swelling gradually increased. On admission the central portion of the tibia was found to be much enlarged, and another swelling was detected at the junction of the lower and middle thirds of the fibula. The leg was amputated in the belief that the disease was malignant. The tibia was found to be the seat of a new growth of fusiform shape, and was bent above and below the tumour. A layer of compact bone was present at the concavity of each bend, apparently thrown out as supporting structures. The tumour of the fibula was independent of that on the tibia. The knife could easily cut sections of the tumours. The new growth consisted throughout of well-formed bone, which was undergoing a process of remodelling just as occurs in the normal growth of bone. The soft tissues of the growth were made up mainly of spindle-shaped cells with a few round and stellate cells. The growth was indistinguishably blended with the osseous tissue of the shaft of the affected bones. The duration of the swelling (two years and a half); the uniform consistence of the growth; the existence of two separate growths; the history of an injury, which was possibly a fracture—all pointed to the view that the growth was hypertrophied callus. Mr. Pollard had met with one somewhat similar instance on the bones of the forearm. The views that the tumour was of a sarcomatous or a simple inflammatory nature were discussed, but rejected as not harmonising with the ascertained facts, though it was allowed that the difference between a hypertrophy of callus and some forms of sarcoma might be a mere question of degree.—Mr. S. G. SHATTOCK asked whether the growth might have been syphilitic.—Mr. H. T. BUTLIN said the specimen was a very remarkable one. He regarded it as a sarcoma, but the fact that both bones were affected and that there was bending of the bones rather went against this view. Still, he thought that it was a sarcoma.—Mr. BILTON POLLARD said there was no history, and no evidence of syphilis.

Dr. W. B. HADDEN showed a specimen from a case of Chronic Cerebro-spinal Meningitis, taken from a boy aged eleven, who died in St. Thomas's Hospital under the care of Mr. Mason. There was a history of phthisis in the mother's family. Fifteen months before admission the boy was hit on the head with a piece of iron. Next day he complained of his head and began to vomit, which continued till death. A year before death the symptoms suggested to Mr. Willmer Phillips cerebellar tumour. Two or three months later the legs became weak, and he lost control over the bladder. He had fits of an epileptic character. The sight had been failing for about two months. On admission, he complained of pain in the head, was drowsy and nearly, if not quite, blind. The pupils were equal, dilated, and sluggish; the eyeballs continually oscillating. There was occasional sickness whilst he was under observation, but no fits. He passed his evacuations into the bed. At the necropsy there were no signs of injury to the bone, and the dura mater was healthy. Both the upper and under surfaces of the cerebellum were covered with an opaque white material one to four millimetres thick. It was beneath the arachnoid, which was for the most part free, but here and there adherent. The tips of the temporo-sphenoidal lobes were similarly affected, but to a less degree. There was much thickening and opacity about the optic tracts and chiasma, and the edges of the fissures of Sylvius were adherent. There was no tumour, and no naked-eye appearances of miliary tubercles. There was a thick white layer beneath the arachnoid over the posterior surface of the entire lumbar and lower dorsal regions of the cord. The arachnoid was adherent to it over the greater part, but here and there it was free, the surface presenting numerous small bleb-like elevations. There was a caseous nodule at the apex of the left lung and a few miliary tubercles in the kidneys and liver. On microscopical examination the thickening over the cerebellum and cord were found to be really organised lymph, but no tubercles were seen. The symptoms followed so directly on the head injury that it is very probable there was a relation of cause and effect. Possibly the injury set up a meningitis of tubercular nature running a chronic course. The limitation of the disease to the base favours this idea. But, on the other hand, the spinal cord was affected—an unusual accompaniment of tubercular meningitis. Pathologically, the disease was a chronic inflammation of the pia mater, but the relation of this to the head injury and to the tubercular diathesis is less clear.—Dr. ANGEL MONEY had seen a case of chronic purulent cerebro-spinal meningitis in a girl aged three years. There was a history of a fall down a flight of stairs, and the symptoms began soon after this fall. Headache, vomiting, and fits of screaming were the early symptoms. The disease lasted twenty-six weeks. Fever, vomiting, universal rigidity, and unconsciousness were the main clinical symptoms. At the autopsy the body weighed only 17 lb. There was much thickening of the meninges, both of the base of the brain and of the spinal cord; a collection of pus existed beneath the cerebellum; extreme internal hydrocephalus was present, and the fluid was purulent in the lateral ventricles, where the ependyma was much congested and coated with velvety lymph. There was no disease of the internal ear. In another case, marked by the same clinical symptoms, extensive syphilitic arteritis of the cerebral vessels was present, with atrophy and sclerosis of the brain and spinal cord, but without meningitis.—Dr. CHARLTON BASTIAN referred to a case in which there was remarkable rigidity. The child had sustained a severe fall about eight or nine months before the disease began. At the autopsy a white sarcomatous growth was found at the base of the brain and extending down the spinal cord, which was thereby ensheathed in the new growth, which was a quarter or a third of an inch in thickness. The disease appeared to have developed as a direct consequence of the fall.—Dr. GOODHART spoke of cases of chronic meningitis in children, and referred to the thickened velvety lymph which adhered to the meninges, and to the presence of pus in the ventricles. Although in a case he specially referred to there was no perforation of the membranæ tympani, still pus was present in the middle ear. In his experience it was not rare for tubercular disease to extend to the spinal membranes.—Dr. NORMAN MOORE spoke of a class of cases which had been described by Drs. Gee and Barlow under the name of cervical opisthotonos; these cases were really examples of cerebro-spinal meningitis, and in many there was a definite history of an injury which seemed to play a causative part in the occurrence of the disease.—Dr. WILKS said it was difficult to diagnose such cases from the clinical symptoms; for although a distinct physiological condition probably underlay them all, yet the pathological lesion was not always the same. The commonest cause of rigidity in his experience was meningitis, and even in Pott's disease accompanied by rigidity there was frequently nothing but a localised meningitis, without sclerosis of the cord. It was very difficult to distinguish between a new growth and an inflammatory product, and he instanced the disease known as cervical pachymeningitis, in which, although there were the causes of inflammation, the material thrown out might not unreasonably be regarded as of the nature of a tumour.

Mr. SHATTOCK showed two specimens of Actinomycosis of the Liver, which he had found in the museum of St. Thomas's Hospital. There was no doubt about the presence of the fungus, and sections were placed under the microscope. With one of the specimens there was a history. The specimen came from a girl aged fifteen, who was believed to have died from "scrofulous" disease, which affected chiefly the ovaries and Fallopian tubes. [In our leading article last week by an oversight we forgot to allude to a case of actinomycosis published in THE LANCET, vol. i., 1884, p. 107, by Dr. Knight Treves. We have to thank Dr. Neale, the author of the "Medical Digest," for correcting this oversight.]

Mr. BLAND SUTTON read a paper on Typhoid Fever in Monkeys. Dr. Budd and Professor Axe considered that the typhoid fever, purple or red-soldier, was the same disease as typhoid fever in man, but Dr. Klein had found that there was nothing in common with the disease in man. Mr. Sutton had reported some cases of typhoid fever which occurred in lemurs living in the monkey-house of the Zoological Gardens. Payer stated that in 1839 M. Serres reported an outbreak of typhoid fever among the monkeys in the menagerie attached to the Museum of Natural History, Paris. The symptoms were diarrhœa, increased frequency of the pulse, and fever, ending almost always in death. In January of the present year there arrived at the Zoological Gardens six Canadian beavers apparently in the best of health. In the course of four or five weeks after their arrival four out of the six animals died, and the remaining two were sent away and recovered. The younger ones were the first to succumb, but in all ulcerated Peyer's patches were found both in the agminate and solitary forms; the ulcers were typical of the disease. In the young specimens the various stages could be seen from the normal Peyerian patches through the infiltration and sloughing stages, with the bile-stained débris still hanging to some of them. Small whitish specks could be seen in the liver of two beavers; these were due to disintegration of minute areas of the hepatic tissue. Despite the negative results of inoculation, Mr. Sutton thought his cases proved that typhoid fever could occur in monkeys.

The following card specimens were exhibited:—

Dr. Charlewood Turner: Posterior Sclerosis of the Cord.

Dr. Goodhart: A case of Cirrhosis simulating Cancer of the Liver.

Mr. Battle, for Mr. Croft: (1) Primary Sarcoma of the Kidney; (2) Fistula between small Intestine and Bladder.

Mr. Doran: Pedunculated Fibroma on the Outer Wall of an Ovarian Cyst.

Mr. D'Arcy Power: Three specimens of an Encysted Hernia.

Dr. Burnet: Much Contracted Right Lung (recent specimen).

Dr. Charlewood Turner: Typhoid Infiltration of Ileum (recent).

Dr. Percy Kidd: (1) Tubercular Ulceration of Tongue; (2) for Mr. H. H. Taylor, another specimen; (3) Small Fibroma of Cæcum.

Mr. Churchill: (1) Congenital Papilloma of Chin, Buccal Mucous Membrane, and Middle Line of Neck; (2) Acute Ostitis of Tarsus following Excision.

Dr. Hale White: (1) Rupture of Aorta; (2) Fracture of Sternum with Disatriculation of Costal Cartilages.

MEDICAL SOCIETY OF LONDON.

Syphilitic Disease of the Brain.—Treatment of Cancer of the Cervix Uteri.

AN ordinary meeting of this Society was held on the 27th ult., Dr. W. Miller Ord, F.R.C.P., President, in the chair.

Dr. ALTHAUS read a paper on a case of Syphilis of the Brain. The patient was a clerk, aged twenty-eight, who had had a hard chancre about four years ago, and after having been apparently well for three years was affected with ophthalmoplegia of the left eye, and six months afterwards with hemiplegia of the right side. When admitted into the hospital he showed almost complete paralysis of all the muscles supplied by the third, fourth, and sixth nerves, including the iris and the ciliary muscle. The intellect was impaired; and there was incomplete hemiplegia of the right side. Dr. Althaus argued that this group of symptoms could only be due to syphilis. With regard to the hemiplegia, he laid chief stress on the age of the patient, the fact that there had been no apoplexy when the stroke occurred, and that the paralysis had been incomplete from the beginning. Ordinary hemiplegia did not occur in the prime of life, except where there was heart disease, or diabetes, or tabes spinalis, or alcoholism; it was almost invariably ushered in by apoplexy, and was complete at least for the first few days or weeks; nor was it accompanied with palsies of the ocular muscles. A peculiar symptom in the present case was an enormous exaggeration of the tendon reflexes in the palsied limbs, out of proportion to the degree of paralysis as well as of muscular rigidity which were present; and Dr. Althaus was inclined to consider this as a pathognomonic symptom by which syphilitic hemiplegia was distinguished from ordinary hemiplegia. With regard to the nature and seat of the pathological lesion, he argued that there was a gumma at the base of the brain, near the inner surface of the crus cerebri, close to the pons Varolii, which, by compression had caused paralysis of the three cranial nerves mentioned, and by further extension later on to the crus itself, which contains the crossed pyramidal strands, caused softening of these parts and thereby hemiplegia. He concluded with some remarks about the prognosis of syphilitic lesions of the brain generally, stating that specific treatment was only successful in primary and truly specific lesions; but where a gumma had already caused wasting of the cranial nerves and softening of cerebral tissue—that is, secondary and non-specific lesions—no amount of mercury and iodide of potassium could effect a cure. From this he drew the conclusion that an energetic specific treatment should be adopted as soon as the slightest symptom of syphilitic brain disease was observed, so as to disperse the primary specific lesions and prevent the occurrence of incurable secondary lesions.—Dr. ORD referred to the difficulties of localisation of the lesion causing the various symptoms in this case. With regard to the symptom specially commented on by Dr. Althaus—exaggeration of the deep reflexes—he should very much like to hear the value of this symptom discussed.—Dr. DRYSDALE said it was since 1858 that our knowledge of cerebral and spinal syphilis had been gained. He referred to cases of syphilitic lesions of the brain which had come under his notice.—Dr. K. FOWLER was interested in the exaggeration of the deep reflexes; he had observed this symptom in neurasthenia from almost any cause. The occurrence of hemiplegia at the period of life mentioned in the paper was not, in his opinion, conclusive of syphilis.—Dr. CLARK asked whether headache had been present in this case. He believed that muscular tone exercised an influence on the deep reflexes. He had seen a case of hemiplegia in the course of renal disease in a young girl.—Dr. ALTHAUS said that in aphasia due to syphilitic lesion the prognosis was gloomy. The deep reflexes were not exaggerated in the side which was not paralysed. Cephalalgia was not present in this case.

Dr. HERBERT SNOW read a paper on the Free Use of Caustic Potash in the Treatment of Cancer of the Cervix Uteri. He reviewed the statistics of extirpation of the uterus, and showed the severe mortality which followed the abdominal or the vaginal operation. In many cases the écraseur was unable to remove the whole of the disease of the cervix uteri. The actual cautery had too superficial an action to be of any great service. Chloride of zinc caused much pain and distress, which lasted a long period. These objections did not hold with regard to potassa fusa. Half an hour or an hour was recommended to be spent in the employment of successive sticks of potassa fusa, for the treatment must be thoroughly carried out. None of the cases suffered from peritonitis; and unless the patient get up too soon after the operation, nothing distressing need be feared. All the cases were greatly benefited, and no alarming symptoms were encountered. Fixation of the uterus and infiltration of the vaginal wall were regarded as prohibiting the employment of this method of treatment. It was only by degrees that he had ventured to apply the caustic so freely as he now advocated. He illustrated the paper by narrating several cases in which the treatment had been adopted. The object of the paper was to show that potassa fusa could do all that the vaginal cutting operation could perform without running the risk of the severe operation.—Dr. EDIS said that he had performed

Marion Sims's operation of the removal of a conical portion of the cervix with much benefit. He did not believe that potassa fusa could exercise any curative influence on malignant disease of the cervix.—Dr. C. H. ROUTH was struck with the circumstance that in the cases narrated the patients died in from four to nine months. He believed that cancer, if left alone, would last longer than if operated on. Potassa fusa in his hands had proved harmful; bromine was the most effectual. External vegetations were best healed by tincture of gall-nuts or hazeline.—Dr. ROGERS said that potassa fusa had been used for all sorts of uterine ulceration; in his hands it had set up so much irritation of the bladder that he was compelled to give up the use of it.—Dr. HEYWOOD SMITH said that potassa fusa was of value in areolar hyperplasia of the cervix uteri. He had observed that Chian turpentine changed the character of the secretions, and in other ways proved beneficial.—Dr. H. SNOW briefly replied.

Mr. SPENCER WATSON showed a case of Exophthalmic Goitre in a female, with slowness of speech and dulness of intellect, in which tonic treatment had been beneficial.—Dr. ORD said that in some of the cases of myxœdema which he had seen he had observed in the early stage symptoms which usually accompanied exophthalmic goitre.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT the meeting on April 17th, Dr. J. ORME DUDFIELD, President, in the chair,

Dr. THOMAS STEVENSON read a paper on Sewage Disposal. The author commenced his paper by expressing regret that the possibility of dealing with excreta directly on the soil with Arcadian-like simplicity was confined to the very few. He said that the processes, inorganic and organic, by which effete matters are got rid of by the soil can be but feebly imitated by man; yet it is by the study of these processes and their more exact imitation that we must look for a more satisfactory disposal of sewage in the future. The author traced the different methods of excrement-disposal, from the primitive privy to the introduction of the watercloset in 1810, since which time the latter has become the common, although by no means universal, method of removal, notable exceptions being found even in large towns such as Leeds, Bradford, and Birmingham, in which there were many houses without waterclosets, while in Stafford a watercloset was phenomenal. At the beginning of the present century, and for long afterwards, cesspools were universal in London, and although sewers existed it was penal to use them for sewage. At this time the river water at London-bridge was drinkable, and many persons still living remember the waterworks opposite Fishmongers' Hall, which were used for the supply of the city. The use of waterclosets increased the volume of water in the cesspools and necessitated an overflow to the sewers, so that in a few years the state of the law underwent a complete reversal; and now, instead of the discharge of sewage into sewers being a punishable offence, it is penal not to drain into a sewer if one be accessible. The author said that the composition of sewage varied much less than might be expected, and that the difference was one of degree rather than of kind; that there was little difference between the sewage of a waterclosseted town and a non-closeted town. Taking the average of the community, the dry solid excrement is 1 oz. per head per day, which is distributed through 300 lb. of water—say, 15 grs. per gallon; and as for the urine, whilst the major portion, of that of adult males, never finds its way direct into the sewers, of the 2½ oz. solids distributed through 300 lb. of water, 1¼ oz. only is organic, one-half of which, urea, is speedily converted into innocent carbonate of ammonia. Although the solid excrement forms the most important polluting agent of sewage, it is by no means the greatest in aggregate amount, and, indeed, forms only a small fraction of the total polluting material, which comes from the innumerable articles of domestic economy. He thought that in no British town could the difficulties attending sewage disposal be greater than those which presented themselves in London—a site much of which is below river level, an immense area, a city remote from the sea, with no available area close to its boundaries, and a situation near the upper end of the tidal reaches. He considered that much credit was due to those who had hitherto dealt with the disposal of the sewage of London, and great blame would rest on the responsible authorities if they did not at once manfully set themselves to do all that can be done to mitigate and abate the nuisance of the filthy condition of the Thames. When fresh and freely exposed to air, as in sewers only partially filled, sewage has little odour, and can scarcely be considered as offensive; but once let it accumulate in large quantities and come to comparative rest, putrefaction sets in, and it becomes vilely odorous—a seething mass full of those minute organisms which live, and grow, and multiply in an airless, deoxygenated medium. To prevent this, sewage must be dealt with in one of three ways: (1) The sewage may be at once thrown into a large volume of water, a river, or the sea, where it can be carried away by currents, diluted by diffusion, and oxygenated by the dissolved oxygen, without appreciable nuisance. (2) It may be applied directly to land, if sufficient area be obtained to dispose of the sewage without offence. (3) It may be treated with chemical agents, such as either destroy the organic matter, or those that destroy the agents of putrefaction, the lower organisms. The author briefly discussed the first method, but only to condemn it, as causing nuisance and danger to health. In speaking of the second method, utilisation on land, he said that while in principle this was no doubt the right one, the fertility of the land being dependent on the restoration to it of the mineral constituents of the food grown upon it, the method from a pecuniary point of view could rarely be profitable, and commonly entailed loss. He estimated the value of a ton of London sewage (the quantity yielded per head of the population per week) if its manurial constituents were in a solid and portable form, at twopence; but when sewage had to be utilised on land in a highly diluted form, and in all weathers, the actual value was found to be only a halfpenny, and this leaves no margin for cost of transport, so that when the sewage had to be pumped the cost of pumping exceeded the value of the article pumped. There is, however, no agent which so efficiently deodorises sewage as the soil, which acts not only as a checker of putrefaction but also absorbs the gases of sewage, and, further, is the nidus of the wellnigh demonstrated nitrifying agent—i.e., the bacterial organism—by which ammonia and nitrogenous organic matter, immediately or through the intermediate stage of ammonia, are converted into nitrates. The author referred to the researches of Schlœsing and Müntz and of Warington to show that it is probable that such a bacterium does exist, and plays some such part in nitrification, as yeast in a saccharine infusion does in setting up alcoholic fermentation. A point of great practical importance referred to in this connexion was that the nitrifying action is limited to the superficial layers of the soil, decreasing as we descend, until, at 18 in. below the surface, the action entirely ceases. This points to the possibility of economy in the cost of carrying out the process of intermittent downward filtration, as, by keeping the superficial layers of the soil in good condition for nitrification, the great expense of deep excavation and preparation of the soil may be saved; while broad irrigation, where a sufficiency of land is available, offers a satisfactory mode of sewage disposal, and is one which holds out more likelihood of realising some portion of the value of sewage than any other. It is seldom, however, for obvious reasons, applicable to the sewage of large towns. There is an erroneous notion prevalent that sewage can be effectually treated by means of chemical substances alone. Any chemical which will effectually destroy the spores of bacteria, or deprive them of potential life, will certainly render the sewage unfit to be disposed of anywhere, for by such addition it becomes a poisonous fluid. Chemical treatment directed to the end of clarifying sewage, but not of rendering it non-putrescent, is a great advantage, for the suspended solids of sewage are the chief source of difficulty in treating sewage. As to the agents to be used for clarification, the author said if the sewage is to be used for broad irrigation, simple straining will suffice; when land filtration is the plan to be adopted, something more is advisable; and when the effluent is to be turned into a stream without any other treatment than a chemical one, efficient clarification is indispensable—such a clarification as leaves less than a grain of suspended solids in each gallon of effluent, and even with this degree of efficiency no effluent ought to be turned into a stream unless the volume of running water is enormous in proportion to the sewage it is to receive. The chemicals to be used for precipitating sewage may be varied. Of these lime has been largely used both on account of its being reasonably efficient and because of its cheapness; it should be dissolved previous to its use. Fifteen grains of lime to each gallon of sewage is an ordinary proper proportion, but it is better to accurately adjust the quantity to the degree of hardness of the water of the district—i.e., one grain of lime per gallon of sewage for each degree of hardness of the water-supply. An excess of lime is hurtful, for subsequent putrefaction is apt to occur; it may kill fish, and according to Warington may entirely prevent nitrification. The addition of a little sulphate of aluminia is beneficial, as it carries down a flocculent precipitate, entangling the lower organisms and their spores, difficult to remove by lime alone. Moreover the use of alum neutralises any excess of lime which might occur in the effluent. Sulphate of iron is another salt which may be usefully employed, but it is questionable whether this is a useful addition when the sewage is subsequently applied to the land. The author concluded his paper with the following remarks: "So far as I can foresee, the sewage disposal of the future for our large towns will be one where application to land supplements a preliminary precipitation process; and the land treatment will be a filtration process by which the area of land requisite will be limited. Such a combined process fulfils all the requisites of good purification, and is based upon these fundamental data. The sewage must be dealt with speedily before putrefaction has begun; and the agents of putrefaction, the bacteria, must be removed by clarification, which secures the removal of most of the bacterial organisms. The precipitated and clarified sewage is then to be brought as speedily as possible under oxidising influence, and nothing more effectively does this than the nitrifying organism. Putrefaction and nitrification are antagonistic processes; and so long as nitrification is going on, putrefaction is, I believe, impossible. Sewage, when clarified by any simple process—and the simpler the better—and then passed through land is odourless, and this cannot, strictly speaking, be said of sewage simply precipitated; and is also insusceptible of putrefaction. Anything that falls short of the result obtained by the combined process I have referred to cannot be considered a very desirable mode of sewage disposal, albeit a less efficient process may under certain circumstances be permissible.—In the discussion which followed Drs. Drysdale, Edmunds, Bernays, C. E. Saunders, and Messrs. Rogers, Field, Corner, Edmunds, Jacob, and Winter Blyth took part.

ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Surgical Section was held on January 23rd, the President, Dr. E. H. Bennett, in the chair.

Professor STOKES, in a paper on Astragaloid Osteotomy in the Treatment of Flat-foot, commenced by drawing attention to the usually accepted theories as regards the etiology of flat-foot—viz., ligamentous relaxation and a paralytic condition of certain muscles connected with the ankle and foot. He adduced various arguments to disprove these views. Attention was drawn to Professor Ogston's researches in this direction, and an account given of the operation he has devised for the cure of the deformity in question; and objections to it were taken, based on the operation being complicated and difficult, and followed necessarily by an obliteration of the medio-tarsal joint. Mr. Stokes believed that the defect causing flat-foot is due, primarily, to alteration in the tarsal bones, notably the astragalus, which change in it may be either congenital or the result of disease—probably rickets,—and that this stretched rather than relaxed condition of the ligaments is a secondary rather than a primary change. In illustration of this view, he exhibited a specimen of the deformity taken from the museum of Trinity College, and for which he was indebted to Professor Bennett. Having regard to the fact that in the irreducible cases of flat-foot osseous deformation is the chief factor, Professor Stokes believed that the rational treatment for such cases should be to deal exclusively with the deformed astragalus, and to do so without necessarily obliterating Chopart's joint. This he did in the case of a youth aged fourteen, and with complete success. The parts to be operated on were rendered perfectly aseptic, and an incision an inch and a half in length along the inner edge of the foot made, the centre of which incision was the prominence caused by the head of the astragalus. At the centre of the incision another was made at right angles to it, a little behind the situation of Chopart's joint, and the two triangular flaps of skin dissected back for about half an inch. A wedge-shaped piece of bone from the enlarged head and neck of the astragalus was then removed with an osteotome, and it was then found that by adducting and supinating the foot the arch was perfectly restored. The wound during its union was aseptic throughout, and the patient afebrile. The method Professor Stokes adopted for keeping the foot in a position of adduction was by the application of a Dupuytren's splint applied as in a case of Pott's fracture of the fibula. The result of the operation was most satisfactory, and casts of the foot, taken before and after the operation, were exhibited.

Mr. KENDAL FRANKS gave the details of a case in which he had performed Ogston's operation for Flat-foot on Oct. 16th last. The paper was illustrated by two impressions, taken in charcoal, of the foot, before and after operation. The first impression showed the foot resting on the length and breadth of the sole; a remarkable prominence on the inside, corresponding to the astragalo-scaphoid articulation, showed where this joint rested on the ground. The second impression showed that the arch of the foot had been restored, so that when the sole of the patient's foot was blackened with charcoal, and she was placed standing on a moistened sheet of paper, the paper received an impression only of the heel, the outer side, and the anterior portion of the foot. The operation wound was perfectly healed on the sixth day, and the highest temperature recorded was 99·2°.

The adjourned discussion on the Operation for Flat-foot took place on February 20th, when Mr. CORLEY said he was satisfied that the disease commences in the ligamentous and tendinous structures; that if the bones eventually exhibit deformity, it is from growth in some direction from which natural pressure has been removed.—Dr. SWAN said that he considered most of Mr. Stokes's statements were misleading, and some of them appeared to him to be erroneous. Mr. Stokes had stated that the deformity of flat-foot was due to a mal-development of the bony structures of the tarsus, and, without considering the degree or state of the affection, he condemned all methods of treatment as useless except the operations, in which doubtless he included Ogston's as well as his own. He had himself seen thirty-four cases in minor or greater degree, and had observed it under three distinct phases. It commenced with the sliding of the astragalus inward and the upper surface of the os calcis relaxing, the ligament connecting the outside of the astragalus with the calcis. This produced, as Mr. Corley observed, an obliquity at the ankle-joint. The axis of the weight was thrown on its side. Next, there was a relaxation of the plantar ligament. Looking at the anatomy of the parts, the outer division of the plantar ligament fills up the sinus pedis, which prevents displacement of the head of the astragalus, but the interval between the os calcis and the scaphoid is lengthened. Mr. Stokes stated he had observed this in persons of robust health; that was not, however, his experience. In the second stage it was accompanied by a fusion of the muscular structures, which were chiefly of the anterior portion of the foot. The adductor pollicis and the muscles on the inner portion of the foot were atrophied, and the bones could be distinctly felt through those muscles. The tibialis posticus was involved. The third and last stage was one for which no doubt an operation of some kind would be desirable—namely, when the sole of the foot was altogether flattened and the head of the astragalus came upon the ground, and he believed also occasionally the projecting point of the scaphoid. With regard to treatment, it would be too much to admit that all those cases which in the first and second stages did not present serious inconvenience were suitable for operation. The true clue to the treatment of the affection in the earlier stages was to approximate the extremities of the tendinous structures binding the bones together. If bony enlargement or mal-development caused the affection, how was it that in all those cases the foot could be reduced to its pristine symmetry by manipulation? That could not be done in the case of bony deformity. There was a distortion and rotation inwards of the astralagus, as Mr. Corley observed, but there was no enlargement until the last stage, when osteitis was the cause of the enlargement of the bone. He had seen spontaneous cures of the affection. In the case of a patient condemned to long-continued rest the foot regained its natural shape. Ogston's seemed to be the natural method to restore the arch of the foot, allowing the gradual restoration of the ligamentous structures, which appeared to be untouched in the operation.—The President (Dr. Bennett) suggested the excision of a wedge-shaped piece from the side of the astralagus without opening the ankle-joint. The first and second stages of the affection were most painful.—Mr. Stokes briefly replied.

Mr. Arthur Benson read a paper describing a case of a gentleman, aged thirty-three years, on whom he had successfully removed an Ivory Exostosis from the Auditory Meatus. He had first used electrolysis to destroy the vitality of the periosteum, and produced thereby a superficial necrosis of the apex of the bony growth, which separated after six weeks. Five months later, the effect of the electrolysis not being sufficient, he employed the dental engine, and, with the assistance of Mr. Arthur Baker, removed the remainder of the exostosis. The patient was seated in a dental chair, and whilst under ether a deep vertical slot was cut in the base of the tumour with the dental saw. Into this a small chisel was inserted, and a slight blow from a hammer served to separate the remainder of the base, and the growth was removed. Recovery was perfect, and when last seen (January, 1885, a year after the operation) there was no sign of a return in the position of the growth, and hearing was perfect. The operation was, contrary to the recommendation of almost all authorities, undertaken before the canal was completely closed by the growth. Mr. Benson advocated the early operation, in such cases, as probably easier to perform, less dangerous to the patient, and, on the whole, more in accordance with the progress of surgery, than the plan of waiting until "total deafness had occurred in both ears," as most authors recommended. The mode of operating adopted in the case seemed to offer excellent facilities for the earlier removal of such growths, without the dangers attendant on the use of the drill or gouge. The cause of the growth was supposed to be bathing in a river, which produced pain in the ears.—Mr. Story gave a brief description of a case of aural exostosis, in which he had some three years ago obtained excellent results by the application of Vienna paste after drilling and electrolysis had failed. The membrane of the drum was perforated during the treatment, but it rapidly healed up, and for the past three years the patient has had no relapse. Exostoses near the external orifice were easy to deal with either by the hammer and chisel or by the dental saw, which seemed an admirable proposal; but growths deep down in the meatus taxed the utmost resources of the most skilful and experienced operators, and should not be touched except in the case of the most urgent necessity.—Mr. Swanzy could hardly imagine a better mode of operating than the one which had been adopted; but he would not have operated in the case in question, deafness being extremely rare as the result of exostosis in the external meatus. Such growths were among the common diseases of the ear, but absolute or serious deafness was uncommon. He would wait until the growth threatened serious and permanent deafness.—Mr. Benson, replying, said the exostosis was a distinct enlargement of the true bone. The whole question was, how much danger there was in the operation. Most patients would prefer one operation than to go once a month to a doctor to have deafness removed.

Mr. Story read a paper entitled Operations for Trichiasis and Entropium of the Upper Eyelid, in which, after criticising the operation proposed by Dianoux, which Mr. Story was *the first* to introduce to the notice of oculists in these islands, he proceeded to describe the manner in which he now operates both for entropium and trichiasis. The method is, with some trifling modifications, the same as that described by Dr. Van Millingen of Constantinople—a transplantation of the ciliary border, without removal of any palbebral skin, the requisite elevation of the cilia being effected, after the completion of Flarer's inter-marginal incision, by inserting a strip of mucous membrane, taken from the patient's mouth, into the space left exposed by Flarer's cut.

After a brief discussion, in which Mr. Swanzy, Mr. Stokes, and Mr. Benson took part, the Section adjourned.

Disused Burial-grounds.—At a sitting of the Consistory Court of London, held on Monday in St. Paul's Cathedral, before the Chancellor, Dr. J. H. Tristram, Q.C., faculties were granted for the use of the burial-grounds of Holy Trinity Church, Gray's-inn-road, and of St. John's, Clerkenwell, as recreation-grounds.

Reviews and Notices of Books.

Cocaine, and its Use in Ophthalmic and General Surgery. By H. Knapp, M.D., Professor of Ophthalmology in the Medical Department of the City of New York. With Supplementary Contributions by Drs. F. H. Bosworth, R. J. Hall, E. L. Keyes, H. Knapp, and Wm. M. Polk. New York and London: G. P. Putnam's Sons (the Knickerbocker Press). 1885.

The New Local Anæsthetic, Hydrochlorate of Cocaine. By Laurence Turnbull, M.D., Ph.G., Aural Surgeon to Jefferson Medical College Hospital, Philadelphia. Philadelphia: P. Blakiston, Son, and Co. 1885.

It is with much pleasure that we record the appearance of these new works on the subject of cocaine. Dr. Knapp points out that no modern remedy has been received by the profession with such general enthusiasm, none has become so rapidly popular, and few have been found to cover so extensive a field of useful application. He has collected in a convenient form almost all that has been written on the subject. He commences with a translation of Dr. Karl Köller's classical paper on the Use of Cocaine to anæsthetise the Eye, and shows that at least a fortnight before the appearance of this contribution in the *Wiener Med. Wochensch.* of Oct. 25th and Nov. 1st, American physicians were well acquainted with the substance of it. Muriate of cocaine was at that time procurable in New York, and they without a moment's delay organised a systematic research into the properties of the new anæsthetic, and managed to find out for themselves pretty well all that was known about it long before Dr. Köller's or any other European publication reached them. The first notice of the new remedy which appeared in any American paper was written by Dr. H. D. Noyes of New York, then travelling in Europe. The first original communications on the subject published in America appeared on October 18th, and were by Dr. C. R. Agnew, Dr. W. O. Moore, and Dr. J. L. Minor. The *New York Medical Record* of October 25th (issued on the 24th) contained elaborate papers by Dr. H. Knapp and Dr. D. B. St. John Roosa. The *New York Medical Journal* of the same date also contained records of cases treated by Dr. W. F. Mittendorf, Dr. E. Gruning, and Dr. D. C. Cocks. Since then hardly a week has passed without the appearance of a dozen or more papers on the subject, the results of which have been recorded and analysed by Dr. Knapp, who justly remarks that they afford a striking illustration of the enthusiasm, energy, and quickness with which the American mind seizes upon everything that is of practical importance. It must be admitted that the English reports were at first very guarded, and that some weeks elapsed before it was fully realised that we were in possession of a new and valuable local anæsthetic. "It is characteristic of conservative England," says Dr. Knapp, "that medical men were waked up to the remarkable advantages of a new remedy six weeks later than their American brethren, whereas with an equal spirit of receptiveness and progressiveness they ought to have been two weeks before them." In reply to this charge we have little or nothing to say; we simply plead guilty. At the same time it is only fair to point out that in some of the London hospitals the restrictions as to the use of new remedies—"trying experiments" it is usually called by committees of management—are so oppressive that the medical officers are precluded from doing their best for the patients under their care. In addition to Dr. Knapp's contributions, the present volume contains articles by Professor Bosworth on Cocaine in the Upper Air Passages, by Dr. R. J. Hall on Cocaine in General Surgery, by Professor Keyes on its use in Genito-urinary Affections, and by Dr. Polk on its employment in Gynæcology and Obstetrics. Dr F. P. Kinnicutt of New York, referring to its value in the treatment of neuralgia, says:—"I have used cocaine in a number of cases of facial neuralgia with very satisfactory results. My experience coincides with Dr. Murrell's in regard to the necessary strength of solutions for external application in this affection—a 10 or 20 per cent. solution is required. I have employed oleic acid as a solvent rather than the oil of cloves recommended by Dr. Murrell. I rub in with the finger eight or ten minims of the oleate along the course of the painful nerve, with the effect of affording speedy and marked relief." An interesting case is recorded of spasmodic asthma relieved by the application of cocaine to the nasal cavities. Dr. Knapp's book is in fact full of interesting cases, and we cordially recommend it to the attention of our readers. It reflects great credit on the author.

Dr. Turnbull's work covers much the same ground, but is less comprehensive. He refers at some length to the value of oleate of cocaine in dental affections, and calls attention to the fact that the preparations in ordinary use are not nearly strong enough. Disagreeable symptoms have in some instances been recorded, but they are of little importance, and for all practical purposes cocaine is perfectly safe. Dr. Turnbull thinks that for hypodermic injection or internal use the dose should not exceed a third of a grain, or at most half a grain, but English observers have recorded the administration of larger quantities without bad effect. Dr. Turnbull's book contains much that is of interest.

The Colloquial Linguistic Faculty and its Physiological Groundwork. By W. H. Walshe, M.D. London: John Bale and Son. 1885.

The profession and the public are alike to be congratulated that Dr. Walshe finds time in the intervals of professional work to take up and analyse such a question as that which is treated in the little book which is the subject of this notice. A year or two since Dr. Walshe published a work on the criticism of dramatic singing, remarkable alike for its fresh originality, its deep learning, and its knowledge of the art which he so well expounded. The present work, though smaller, has the same characteristics as the former, to which it seems to us to form a fitting sequel, and we can only hope that the two may eventually be published in one volume. As a teacher of medicine, Dr. Walshe was noted for the minute and painstaking accuracy of his investigations into the cases under his care, for a marvellous acuteness of hearing when engaged in auscultation, for his lucid and elegant style of exposition, and for his flashes of incisive humour, which served to fix the attention even of the greatest dullards. Those who have benefited by the teaching of the physician will be glad to spend an hour or so with their old master, and to recognise the same power and qualities brought to bear upon a subject of the very highest importance; for is it not true, as was said we fancy by Lord Chesterfield, that "he who knows two languages is twice a man"?

Dr. Walshe believes that the real colloquial acquisition of any tongue other than the mother tongue is given to very few, and that the faculty of acquisition is extremely rare. He says:—

> "In sober truth, an absolute practical and critical mastery of even the humble number of two or three languages has seemed to me, in my life's journey, a form of accomplishment of singular and in some sense unaccountable rarity. Let me, in justification, instance a pair of languages—those of England and France—countries whose inhabitants are placed in circumstances of locality and of political, commercial, and social relationship (antagonistic though it often be) tending in the strongest manner to familiarise each of the two nationalities with the language of the other. Now, to graduate as a thorough master of both tongues a man of education should be able to read Shakespeare and Corneille, Shelley and Lamartine, Moore and Béranger with a cultured native's keen intellectual and emotional perception of every shade of beauty in their lines; to seize with equal facility the uproarious fun of a burlesque at the 'Gaiety' and the double meaning of a scampish farce at the 'Palais Royal'; to follow with a like ease the eloquent exposition of a Tyndall anent the origin and destiny of man, and a poetic rhapsody at the Sorbonne by Michelet (were he still alive to electrify the historical student) on the ferocities of mediæval barbarism; to lose no single point in a chansonette by Chaumont, or a serio-comic street-arab ballad of Nelly Farren; to hold his own equally well in money disputes with the cabmen and laundresses of Paris and London; to enjoy as thoroughly the humour of *Punch* as the wit of the *Charivari*, and the grave polemics of the *Revue des Deux Mondes* as those of the *Quarterly Review;* to possess the financial vocabulary of the Bourse and of Capel-court; to speak the two tongues with at least a fair share of the intonation, inflection, vocal ring, pronunciation, accent and fluency, distinctive of a native's delivery of each; and, finally, to translate from either language into the other with correct phraseology, word collocation, and idiom, an epigrammatic article on the topics of the day, and a serious disquisition on a problem of art or literature. Now, how many men are likely to be found thus qualified on either side of the Channel? Would Mezzofanti, on these lines, have taken a bachelor's degree in any notable minority of—heaven save the mark!—his forty familiar tongues?"

That persons possessing the colloquial faculty in the degree above sketched, or in anything approaching it, are excessively rare will be at once conceded. The faculty consists, as Dr. Walshe is at great pains to show, in the fortuitous concourse in the same individual of a variety of conditions, physiological and social, and his work goes to prove that the man who has a "genius" for talking foreign tongues is born with it, and that education can add something only to the congenital faculty.

The conditions regulating the colloquial linguistic faculty are, according to Dr. Walshe, (*a*) cerebral (1, formative word-centre; 2, emission word-centre; 3, audition centre; 4, tone centre; 5, motor word-centre; 6, imitative faculty; 7, memory; 8, automatism; 9, unconscious cerebration; 10, anastomotic association); (*b*) muscular; (*c*) sensuous (organs of sight and hearing); (*d*) social (international intercourse, foreign marriage, social status); (*e*) personal, sex, age, temperament, health, heredity; (*f*) national.

Our readers will at once see how unanswerable are many of the arguments foreshadowed in the above tabular statement. But those who wish to be both instructed and amused must read the arguments as put forward by Dr. Walshe, whose book deserves to be widely read, containing as it does much important matter of practical use to many sections of the public, including physiologists, schoolmasters, and ministers of education.

Studies from the Biological Laboratory of the Johns Hopkins University, Baltimore. Edited by Newell Martin and W. K. Brooks. Vol. ii., No. 4.

This number contains—1. Notes on the Development of Panopæus Sayi, by E. A. Birge, with four plates. 2. The Structure and Growth of the Shell of the Oyster, by Henry L. Osborn, with one plate. 3. The Nervous System of Porpita, by H. W. Conn and H. G. Beyer, with one plate. 4. The Presence of Ciliated Epithelium in the Human Kidney, by A. H. Tuttle, with one plate. 5. On the Effects of Variations of Arterial Pressure on the Duration of the Systole and the Diastole of the Heart-beat, by W. H. Howell and J. S. Ely, with one plate. 6. Notes on the Medusæ of Beaufort; Part ii., by W. K. Brooks, Ph.D. 7. The Action of Ethyl Alcohol upon the Dog's Heart, by H. Newell Martin and Lewis T. Stevens. 8. The Direct Influence of Gradual Variations of Temperature upon the Rate of Beat of the Dog's Heart, by H. Newell Martin. Vol. iii., No. 1:—1. H. W. Conn: Significance of the Larval Skin of Decapods, with two plates. 2. By the same author: Life History of Thalassema. 3. Henry

L. Osborn: Of the Gill in some forms of Prosobranchiate Mollusca. Vol. iii., No. 2:—1. W. H. Howell: Notes on the Composition of the Blood and Lymph of the Slider Terrapin. 2. By the same author: The Origin of the Fibrin formed in the Coagulation of the Blood. 3. H. G. Beyer: On the Action of Carbolic Acid, Atropia, and Convallaria on the Heart, with some Observations on the Influence of oxygenated and non-oxygenated Blood, and of Blood in various degrees of Dilution, with a plate. 4. The Action of Intermittent Pressure and of Defibrinated Blood upon the Bloodvessels of the Frog and the Terrapin, by L. T. Stevens and F. S. Lee.

New Inventions.

POCKET CASES FOR HYPODERMIC MEDICATION.

THE new complete pocket case for hypodermic medication brought out by Messrs. Burroughs, Wellcome, and Co. is admirably adapted to the purposes for which it is intended. Its small compass, its compactness, its inexpensiveness, and its completeness render it an invaluable addition to the physician's armamentarium. It contains a hypodermic syringe with two sharp needles, a miniature glass pestle and mortar, and ten small tubes containing the compressed tablets of the various medicaments mostly employed in hypodermic injections. The compressed tablets, of which we have already given our judgment, are easily crushed in the little mortar, and readily dissolve in a few drops of warm water. We can testify to the ease and rapidity with which a hypodermic injection can be prepared from these compressed tablets, which are made up with sulphate of soda. In our experience the use of these tablets has not been followed by any local irritation or unpleasant effects.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE first annual general meeting of this Association was held on Tuesday last, at 4 P.M., at the Westminster Town Hall. The chair was taken by Dr. G. Danford Thomas, the coroner for Central Middlesex. The meeting was very numerously attended.

The CHAIRMAN, in opening the proceedings, endeavoured to show what an important part of the medical profession the Members of the Royal College of Surgeons were; they constituted the rank and file of the profession, and it was to their efforts that we owed whatever of medical reform had been brought about. Though much reform was still needed in the cause of medical education, yet this could not be accomplished without the passage of a Medical Act Amendment Bill through Parliament. Meanwhile it behoved the profession to look at home, and he considered that there was good cause for reform in the Royal College of Surgeons. The Council of the College had almost estranged the Members of the College from their *alma mater*, and he considered that by their recent action the Council had treated the members with marked discourtesy. He intimated that the Association of Members was in communication with the Privy Council, and it was certain that no new Charter would be granted to the Council of the College without the Members of the College having a voice in the matter. The Members of the College should not cease to exert themselves until they had obtained their just electoral rights. Although the projected new Charter sought to effect some reforms in the constitution of the College, yet he ventured to believe that there was need for much greater reform than that sought by the Council. The first object to be attained by this Association was the direct representation of the Members of the College on the Council; other rights would then necessarily follow. At Liverpool, on May 1st, a large number of Members of the College had held a meeting, which pledged itself to support the objects for which the Association of Members had been founded.

Mr. ASHTON ELLIS, one of the hon. secretaries, then read the first annual report of the Association. The report gave an account of the transactions which had taken place during the past year, including the causes which had given rise to the formation of the Society, and the various means which had been adopted to effect the purposes which the Association had at heart.

Dr. W. C. STEELE then read the financial report, which showed that considerable expense had already been incurred.

The CHAIRMAN proposed that the reports of the Secretaries be received and adopted.

The following list of officers for the ensuing year was proposed and accepted:—President: Dr. Robert Collum. Vice-Presidents: Mr. Joseph Smith, Dr. Danford Thomas, Mr. R. Hicks (Ramsgate), Dr. G. H. Batterbury (Wimborne), Deputy Surgeon-General E. McKellar. Hon. Secs. and Treasurers: Dr. Warwick C. Steele, Mr. J. Nield Cook, Mr. W. Ashton Ellis. Central Committee: Dr. T. Stretch Dowse, Mr. Kenneth Cornish, Dr. C. Royston, Mr. G. Brown, Dr. R. Paramore, Mr. M. G. Biggs, Dr. T. Robinson, Mr. J. Brindley James, Dr. J. W. Barron Mason, Mr. T. H. Sawtell, Dr. Joseph Rogers, Mr. F. J. Pearse, Mr. Horace Watts, Mr. W. G. Dickinson, Mr. John C. Smith, Dr. A. W. Orwin, Mr. W. Outhwaite, Mr. Maurice Clifford, Mr. A. H. Robinson.

Dr. COLLUM moved the following resolution:—"That this meeting protests vigorously against the conduct of the Council of the Royal College of Surgeons in refusing all the demands of the Members of the Royal College of Surgeons."

Mr. JOSEPH SMITH seconded the resolution, and referred to the deputation from the Association which the President and Vice-Presidents of the Royal College of Surgeons received in the early part of the year. The result of that deputation consisted in an answer but recently received, in which the Council of the Royal College of Surgeons practically refused to acquiesce in the demands of the Association. He said that it was probable that the Association of Members would go hand in hand with the Association of Fellows. He read extracts from the letter of Mr. Reginald Harrison which appeared in THE LANCET last week.

Mr. JABEZ HOGG spoke on the resolution, which was unanimously carried.

Dr. JOSEPH ROGERS proposed: "That this meeting urges that immediate steps be taken to prevent any alteration of the said Charter until it has received the general sanction of the Members, for which purpose the Privy Council be requested to receive a deputation to explain the views of the Members, supported by a petition to the House of Commons."

Mr. OUTHWAITE seconded the resolution, which was unanimously carried.

Mr. HORACE WATTS proposed the third resolution: "That this meeting considers that no alterations in the Charter of the Royal College of Surgeons should be allowed without provision being made for the due representation of the Members upon the Council."

Mr. H. T. SHAPLEY (Leamington) seconded the resolution, which was also unanimously carried.

Mr. HOPPER said that the feeling of the Members at the meeting at Liverpool coincided with that which existed at the present meeting, and the Liverpool meeting had passed resolutions to the same effect as those now adopted.

Mr. KENNETH CORNISH considered some modification should be introduced in the bye-laws respecting the mode of election of members of the Board of Examiners.

The meeting then agreed that a copy of the resolutions should be forwarded to the Council of the Royal College of Surgeons and to the Secretary of State for the Home Department.

THAMES VALLEY DRAINAGE.—The Acton Local Board has issued a communication to the various local boards of the western and northern districts of the metropolis, asking their co-operation in the carrying out of a combined drainage scheme prepared by Sir Joseph Bazalgette. The salient features, which comply as far as possible with the recommendations of the Royal Commission on Sewage Disposal, are the laying of a main collecting sewer from Chiswick to Acton, Ealing, and through Willesden, and northwards through the parishes of Leyton, Edmonton, Tottenham, and then eastwards to Barking, where the sewage will be treated before it is passed into the River Thames. The liquid sewage, after it has been chemically treated at suitably constructed works, will be filtered through a certain area of land. Some of the boards have refused to entertain the proposal, while others have promised to give it consideration.

THE LANCET.

LONDON: SATURDAY, MAY 9, 1885.

SEVERAL important meetings have taken place during the past two or three weeks in which this subject had an important place, and the progress of the movement has been one steady advance all along the line. On Monday last a conference was held between the members of the Subcommittee for Medicine of the Association for Promoting a Teaching University for London and a numerous body of delegated representatives from the London Medical Schools, and the outline of a plan for the constitution of such a University was submitted for consideration, and met with an almost unanimous reception. It will be composed of Faculties of Medicine, Science, Arts, and Laws; Boards of Studies; and a Governing Body, and to the constitution of a Faculty of Medicine, comprising all the *bonâ-fide* teachers in the medical schools, there was a cordial assent on the part of those who were present. The consideration of the constitution of the Boards of Studies and of the Governing Body was postponed to the next meeting on the 18th inst. It is expected that the faculties will elect Boards of Studies to conduct the examinations and lay down the conditions of degrees, and that the teachers will be directly and substantially represented on the Governing Body. The great defects in the constitution of the present university are, as we have pointed out, the non-existence of Boards of Studies as a medium between the teachers and the executive, and the absence of teachers on the executive, as the result of the present method of selection and nomination. These defects cannot exist by the proposed constitution on the new body, and the members of the executive will only be elected for a term of years instead of for life. It will thus be seen that the executive of the new Association has formulated a distinct and well-considered scheme, based on the experience of the older Universities, and essentially different from the present constitution of the University of London, and that such a scheme is in accord with the wishes of the teachers, and will be the basis of the reform which the University of London must prepare to grant if it is to stand in its present position as the Metropolitan University. The charge of vagueness in the aims of the Association is no longer tenable, and the name of a Teaching University is sufficiently justified by the scheme of its promoters. Whether one University is to rule education in London, or whether a rival is to be founded, will depend on the attitude of the members of the Senate of the existing institution; and as we should regret that two rival bodies should exist in London for the direction of the higher medical education and the conferring of degrees, we are glad to see that there are already some signs of a departure from the old *non possumus* on the part of the authorities of the present University. As was so ably urged by the deputation of the Metropolitan Counties Branch of the British Association, students who are well taught and of average industry should be able to obtain degrees, but for these they are obliged to leave London and reside at schools of medicine elsewhere. At the recent First M.B. Examination of the University of Durham, held at Newcastle-on-Tyne, only three students who passed had been taught locally, and the remaining twenty-nine, who came from Birmingham and the metropolis, will have to spend a year in Newcastle in order to obtain a degree, when they might pass that time in observing the greatest variety of medical and surgical practice and attending to the best clinical instruction in the kingdom by a residence in the metropolis. The reasons for the large entry of students at schools where degrees can be fairly obtained are obvious, and have but little to do with the teaching at such schools, and this is attested by such an exodus from London in the third or fourth year of studentship as that to which we have just referred. Every student is now aware that mere qualifications have not the same commercial value as a degree or title, and he will leave the best teaching if he can obtain a degree at another place. The greatest impediments to obtaining degrees in London are the non-medical examinations—viz., the Matriculation and the Preliminary Scientific M.B. Each of these requires special training, and a failure, owing to the absence of due facilities, so increases the time necessary to go through the curriculum, and the expense attendant thereon, that comparatively few, even well-informed and well-taught students, care to incur the risk. We are pleased to find that the Senate has come to a wise resolution regarding the Preliminary Scientific Examination, which should have been passed many years ago, and for which it would then have been thanked as a considerate reform, whereas now it is only supposed to have yielded to the pressure of the new movement. It has determined "that the Preliminary Scientific M.B. Examination be held twice a year; once, as at present, for Pass and Honours, in July, and once for Pass candidates only, in January." We believe that this resolution only awaits the sanction of the Home Secretary to come into force, and that students who pass in two subjects will not be re-examined in those subjects. A report by the Annual Committee to Convocation, at the meeting on the 12th inst., will give the Senate the opportunity of dividing the subjects of the Matriculation Examination in a similar manner, and we hope that it will make use of the occasion to alter the conditions of what is perhaps the most ill-judged, as well as the most stringent, preliminary examination in existence. But for the constant supervision of regulations and the guidance of the examiners, Boards of Studies are a necessity, and life-senatorships must be abolished before any real sympathy can be looked for between the students and the teachers on the one hand, and the executive on the other. Unless these reforms be forthcoming, the demands for a title or a degree by the members and licentiates of the Royal Colleges will gather strength, and we therefore welcome these suggestions of the promoters of a Teaching University, and are pleased to know that conclusions practically identical will soon be placed before the Senate of the University by the Sub-committee of the Convocation of the University. As a result of pressure from within and pressure from without, the Senate must yield to one of the most urgent educational demands of our time.

◆

"MENE, MENE, TEKEL," is written on the walls of the council-room of the Royal College of Surgeons; *but there* is apparently no DANIEL there to interpret the signs. The Fellows and Members are in revolt; but the Council, shut up in a fool's paradise, hears and sees nothing but assurances of absolute confidence and goodwill. A rude awakening may, however, be at hand. The Association of Fellows has proposed a scheme of reform which it will not sacrifice to the obstinacy or complacency of the Council; and it will be seen from the report in another column that the Association of Members has adopted even a more spirited and daring policy. Deliberately excluded from participating in the affairs of the College, and persistently ignored by the executive, the Members of the College of Surgeons have hitherto been denied and refused any corporate rights whatever beyond the payment of the fee of initiation. Numerically constituting sixteen-seventeenths of "the body politic and corporate," the Members have hitherto had no higher political status than that of *Licentiates.* For eighty-five years "THE ROYAL COLLEGE OF SURGEONS OF ENGLAND" has been the four-and-twenty gentlemen who have, by any means, succeeded in gaining admission into the Council. For forty-three years, or more than one-half of its total existence, this body of gentlemen was self-elected, and members of Council held office—which not seldom was highly lucrative—for life. This abuse was abated somewhat forty-two years ago, when the order of Fellows was instituted, from and by whom members of Council have since been elected. But the benefits that might otherwise have arisen from this extension of the franchise were craftily controlled and checked by the conditions which were imposed as to eligibility of candidates for seats in the Council and as to the mode of voting. Even under the amended Charter of the 15th of Victoria, it is provided that only Fellows who are of fourteen years' standing, and who are in practice of their profession of *surgeons*, are eligible as members of the Council; while the Charter of the 7th of Victoria provides that the voting shall be in person only. The effect of these conditions is, firstly, to render ineligible every Fellow of the College who does *not* practise what is called "pure surgery," and thereby to exclude all persons practising as physicians, apothecaries, or general practitioners, or who are devoted to biological science; and, secondly, to reduce the electorate to the two or three hundred Fellows who are able or willing to vote in person. Hence, practically, less than one hundred of the seventeen thousand members of the body corporate are eligible as members of Council, and of these any one may be elected into the Council by less than one hundred votes. Nor is this the worst. Once in the Council, a Member becomes henceforth and wholly irresponsible and unaccountable to those whom he nominally represents. Criticism and attempts to control the Council have been alike resented, and until within a few years many of its members lacked only the power, not the will, to make any published report of its transactions a penal breach of privilege. Under cover of its factitious sanctity the Council has perpetrated almost every form of corporate injustice and abuse. Its members have been permitted, as examiners, to appropriate one-half of the total revenue of the College; and undertakings which materially affect the status of the Fellows and Members, and alter the relations and constitution of the College, have been entered upon without even the knowledge of the Fellows and Members. For instance, the Fellows and Members were not consulted as to the wisdom, prudence, or propriety of the compact with the College of Physicians to hold a combined examination, nor have they been asked to sanction the arrangement which the Council has entered into to devote several thousands of pounds of the College funds to the erection of a building in Long-acre for the purpose of holding this conjoint examination.

Happily for the interests of medical education and practice in England, this autocratic career of selfishness, exclusiveness, and irresponsibility is nearly run. The Fellows and the Members of the College have developed active organisations for the eradication of these evils and for the effectual reform of the Council. Indeed, the danger at present is that the reaction may be too violent. It will be remembered that the Association of Fellows has recommended that *any* Fellow of ten years' standing shall be eligible as a member of the Council, whatever his sphere of practice or study, that not more than one-half of the members of the Court of Examiners shall have seats in the Council, and that no alteration shall be made in the constitution or relations of the College without the consent of the Fellows and Members. These recommendations, though unacceptable to and unaccepted by the Council, have been cordially approved by the Association of Members, and thus supported will no doubt commend themselves to the Secretary of State, to whom an appeal from the Council is about to be made. From the report of the annual meeting of the Association of Members, published in another column, it will be seen that this body is determined to extend to the utmost limit the sweep of reform, and to secure for the Members of the College direct representation upon the Council. The reasonableness and substantial justice of this endeavour cannot be called in question. It only remains for the Association to define what it believes to be the "*due representation*" of the Members, and to devise some scheme whereby these may be most easily and safely obtained, with the single aim and purpose of securing for the College that place in public and professional confidence and respect to which it is at present a stranger, but to which it is entitled by its importance and influence as an examining body and by the number and status of its *alumni.*

◆

IT was in 1857 that the Royal College of Physicians first undertook the compilation of a catalogue of diseases and morbid states, for the purpose of rendering the registration of disease more precise, and it was in 1869 that the first issue of the "Nomenclature of Diseases" was made to every member of the medical profession in Great Britain and Ireland. The work was issued subject to decennial revision, and accordingly in 1880 the College took steps for prosecuting the work anew. The Joint Committee, eventually formed, included members specially familiar with different departments, and the fruit of their labours is now being distributed throughout the kingdom. Of the need and value of the work it is hardly necessary to speak; the widespread use to which the Nomenclature has already been put affords sufficient testimony on that head. Statistical tables are drawn up on its plan, systematic treatises are written within its lines, and opportunity is given for greater precision in returns than could have been possible before. But with advancing knowledge and clearer insight into the nature and relations of morbid processes, there must of necessity be changes in terminology; and this the first revision of the Nomenclature illustrates in a striking manner. Terms that have fallen into disuse have disappeared, names of conditions which have become differentiated by more strict analysis are introduced, and the work marks the standpoint at which we have now arrived. That errors of omission may have occurred in the progress of so difficult a work is only natural, and that—as one critic has recently pointed out in our columns—there are even some errors committed is not to be wondered at; but the work as a whole represents well the most complete, and at the same time the simplest, attempt at a nosology that exists in literature.

It would scarcely be within the province of this article to analyse in detail the pages of this Nomenclature; but it may be well to indicate its general principles, and to illustrate some of its features by examples. In the first issue great pains were taken to supply a definition to each of the diseases included under the head of General Diseases. However useful such a plan might be, it had obvious disadvantages, for a precise definition of some diseases is hardly attainable. It is almost conterminous with a description Moreover, if such definitions were essential they should be applied to every section of the work, with the result that it would not only attain undue proportions, but would become a dictionary rather than a catalogue. All such definitions have therefore been rigidly excluded from the revised work; and although synonyms are freely introduced, a limit has been placed upon them wherever they have not received the sanction of a tolerably general employment. Thus, we do not find Dr. Carter's term, "spirillum fever," placed among the synonyms of relapsing fever, although "pythogenic" is retained as a synonym for "enteric" fever. The phrase "simple continued fever" is retained with the synonym "febricula"; but this lax expression, which medicine has as yet been unable to dispense with, is guarded by a definition that leaves it as indefinite as ever. The term still figures in mortality returns, and is a standing protest against the lack of diagnostic precision, just as under the cover of "infantile remittent," typhoid fever and tuberculosis have often been concealed. Amongst the new terms introduced in the list of general diseases are "epidemic rose-rash," a rather cumbrous equivalent for the expressive German word "rötheln"; "typho-malarial fever," the modified typhoid that prevails so much in the United States and elsewhere, but is practically unknown in this country; "malarial cachexia," "myxœdema," "parangi," of which a definition would have been welcome; "leucocythæmia," unqualified by the terms "splenic" or "lymphatic"; "hæmophilia"; "idiopathic anæmia," with its synonym "pernicious"; and "glycosuria." It will be observed also that the Committee have reverted to the terms "rheumatic fever" and "rheumatism" instead of acute, subacute, and chronic rheumatism; that they employ "osteo-arthritis" in preference to "rheumatoid arthritis," and "gonorrhœal arthritis" in preference to "gonorrhœal rheumatism." In all these directions we think they will meet with approval, as also in the omission of the term "puerperal fever" from the list. This authoritative step should do a great deal towards the discrimination of puerperal disease. The enumeration of morbid processes which opens the work is a new feature, as also is the nomenclature of syphilitic and tubercular conditions, all of which are in constant use in the description of local diseases. In the appendix, are to be found lists of parasites—of course exclusive of the boundless class of fungi and bacteria, but of truly remarkable length; lists of malformations and of tumours, the latter obviously based upon Virchow's classification.

Turning to the sections devoted to local diseases, one is struck by the fact that terms which were formerly current, being descriptive of symptoms rather than of the morbid states underlying them, are gradually being dropped. It will of course be very long before pathology is sufficiently advanced to enable us to give a name to every condition that is met with; and in the section on nervous disease the Committee, have decided to draw up a double list—one as it were denoting the pathological, the other the clinical, aspects of the affections met with. The section on diseases of the eye is much elaborated, and presents in several aspects—e.g., in the case of cataract—the more thorough and extensive knowledge which has been gained since the first issue of the work. Among diseases of the larynx we find "croup" retained without any qualification, and perhaps the Committee felt that it was best to leave it so than to introduce the adjective "membranous." Yet we would fain have seen this word eliminated, except in the symptomatic sense. Again, why are the terms "acute pneumonic" and "chronic pneumonic" prefixed to "phthisis"? and for what reason is it preferred to use the phrase "black induration" rather than "iron-grey induration" of the lung? or to retain "millstone-maker's phthisis," "grinder's asthma," and "miner's asthma," instead of recognising the existence of a group of diseases due to inhalation of dust, and classing silicosis, anthracosis, &c., as their varieties? There is altogether a lack of grasp in this section, or at any rate a want of appreciation of the distinctions created by modern pathological inquiry. "Acute nephritis" has been, and rightly, preferred to "acute Bright's disease," and practically the phrase "Bright's disease" is to be limited to "granular kidney." The list of surgical operations has been very much extended, and a comparison with the former edition will show how numerous have been the new operations introduced in the past decade. On the whole, we are well satisfied with the manner in which the work has been presented, and believe that it will do much to ensure accuracy in the description as well as in the registration of disease.

◆

Seldom have the Fellows of the Medical Society of London been more fortunate in their selection of Orator than in choosing Professor Humphry, whose address on Monday last was highly appreciated. Our readers will be enabled to judge for themselves of the manner and matter of this philosophical contribution to a subject of universal interest, for Professor Humphry dealt with his theme—old age—in a manner which could not but compel the attention of his whole auditory. By a most skilful use of antithesis he contrasted the natural life with the actual life as seen in Nature, and once more illustrated the truth of the statement that civilisation with its attendant sympathy defeats the operation of the law of so-called natural selection. For, as he so powerfully sketched, in nature the victory is to the strong, and decadence is anticipated by early death from lack of ability to contend against superior force. And yet if the animal body were suffered to pass unchecked through all its physiological changes, it would be seen that the decline of life proceeds as regularly and as harmoniously as the rise towards maturity. Just as all the constituent parts and organs are evolved from the germ, and co-operate in due proportion and harmony to the sustenance of the body, so when maturity is past and the downward process of development sets in, it does so in an orderly manner, without any derangement of the same harmonious working that was essential in the time of vigour. The body fails, as a whole, just as it is built up from a mass of protoplasmic cells; and healthy old age terminates in physiological death, which may be brought about by the slightest external interference, or by the inability of the vital organs to continue any longer to labour. This ideal picture is, however, the exception, for most men die prematurely. The survival of the fittest still obtains among mankind, but in a different sense from that in which the biologist employs it. Longevity implies the continual maintenance of health—that is, the preservation of each and every part of the bodily mechanism in its due proportion. Hence it is that only those who, by inherent quality of tissue, or by freedom from exposure to external influences that act injuriously upon the frame, or by strict regulation of habits and modes of life in accordance with the capabilities of the organs of the body avert untoward influences, who can expect to attain true old age and be eventually liberated by a painless normal death. Civilisation, that has done so much to prolong life by caring for the aged and helping those who are no longer able to help themselves, has done quite as much to defeat this object by rendering humanity more liable to disease, and even by introducing disease among mankind. Nature therefore asserts her sway, and premature death is still the rule; so that, when one considers how multifarious are the ways whereby degeneration and disease may attack the body, how insidious often is their approach, and how much they are favoured by the artificial and arduous existence of a restless and laborious community, we may be thankful that, in spite of all, the ideal old age sketched by Professor HUMPHRY is not only possible, but is probably year by year becoming more likely of attainment.

Many of the facts concerning the physical characters of aged persons collected by Professor HUMPHRY, by means of the Collective Investigation Committee, are at first sight contrary to preconceived ideas. That females are longer lived than males is to be expected, but it is interesting to learn that members of a phthisical family may attain great ages; indeed, in such proportion that the assertion is warranted that "the delicacy or peculiarity, whatever it be, of constitution, which is associated with the tendency to the development of tubercle, is not only not incompatible with longevity, but is not unfrequently associated with it." One can imagine that having lived through the period at which such individuals would be most disposed to tubercular infection they have lost the liability to it, for phthisis is pre-eminently a disease of adolescence and early maturity. Professor HUMPHRY dwelt at some length upon the skeletal changes that occur with advancing years, showing that the absorptive changes which take place in the cancellous tissue, and which so predispose to fracture of the neck of the thigh-bone and determine the loosening and falling of the teeth, are combined with increased ossific deposit on the surface of the long bones, whilst in the skull there is often a great increase in thickness, determined apparently by the shrinking of the brain. The statement that the rib-cartilages retain their elasticity, and the inference that their calcification is a morbid and not a natural process, will come upon most of us as a surprise, and so also will the statements made with regard to arterial degeneration and to the other processes which have hitherto been regarded as senile. It is a remarkable fact that in 362 persons above the age of eighty, the arteries were tortuous in only 71, and that in 311 the pulse is returned as being compressible. In the male, prostatic affections are not so frequent as is generally supposed; but on this and other points it will be well to await further evidence before drawing conclusions. It is doubtless true that the aged body is far less prone to disease than the young and mature; whereas the reparative power after wounds would, according to Professor HUMPHRY, seem to be remarkably active—a fact for which we have not as yet a sufficient explanation, although, as he pointed out, the same ready tendency to heal is to be seen in subjects otherwise debilitated. In this, as in other parts of his address, Professor HUMPHRY has suggested lines of inquiry which will well repay extended and careful investigation; and we doubt not that his words will greatly stimulate others to join in the work.

Annotations.

"Ne quid nimis."

OUR TROOPS IN THE SOUDAN.

IN our last issue our Special Correspondent in the Soudan, Surgeon C. L. Cunningham, forcibly draws the attention of our military authorities to the peculiarities of the climate, and at the same time warns them of the great danger likely to be incurred by leaving our officers and men exposed to its extraordinary summer severity. In this opinion we quite concurred, and had in these pages previously drawn attention thereto. Although our representative has spoken out fearlessly, and put forth statements that appeared almost incredulous regarding the terrible temperature of the Soudan during the hot months, and under which our troops would be compelled to eke out a truly miserable existence, we were scarcely prepared to receive so early a verification of it. The graphic and startling letters just come to hand from that hot quarter tell a sad tale of mournful suffering, and go far to prove that our representative has rather under- than over-stated facts as regards the rapidly-increasing temperature that sets in about the beginning of May, whilst they show that the prognostications put forth in our columns a week ago respecting the physical torture and mental suffering likely to be endured by our poor fellows when it becomes even warmer, are already, unhappily, more than fulfilled word for word, judging by that agonising appeal made publicly for relief from their protracted sufferings by those officers who have reluctantly been compelled to pen the letters in question. Take the following as a specimen:—

"Each day is twenty-four hours of physical torture and mental suffering. Seven of our men have died of enteric fever in the last twelve days, and although we only began to form our camp here five weeks ago, we have already 150 sick here. The food is bad, and we are still in rags, as no clothing has come up yet. No one speaks, thinks, or hopes anything but to go down. Anyhow, if they do keep the troops here all the summer, none will be left worth a straw. For God's sake write about it, and get other correspondents to take it up. They are generally the best friends the troops have, and now they are gone everything is concealed, and there is no one to say a word for the soldiers. Believe me, half of us will be lunatics before long."

SMALL-POX RISKS.

WHILE some members of Parliament are trying to make themselves conspicuous by attempts to disparage vaccination, the plague of small-pox is extending its deadly work in London and some of the provincial towns in a most painful manner. Mr. Hopwood bores the authorities of the Local Government Board with attempts to find out whether a case of small-pox has not somewhere occurred after revaccination—not content with the fact that for fifty years revaccination has been protective enough to save all the *employés* of the Highgate Small-pox Hospital from an attack, excepting one unfortunate man, a temporary gardener, who refused the boon and paid for his folly with his life, and the similar experience of all the hospitals in London, not only as to the security of the revaccinated, but the almost unfailing attack of those who neglected or refused to be revaccinated. It is not necessary to pretend that revaccination is an absolute protection; but it is very nearly so. Small-pox itself does not absolutely protect from small-pox. Unreasonable people every now and again turn up who have a second or even a third attack. Good revaccination in adult life seems a much more complete protection than a previous attack of small-pox. But no sensible person would be surprised at an exceptional case of small-pox after revaccination. The broad and undoubted protection conferred by revaccination remains, and staggers the detractors of a discovery which exceeds all others in its beneficence. It is most lamentable to have to record the occurrence of small-pox in Colonel Kennedy and others of the Canadian boatmen, since their arrival in London, on their way home from services so efficient on the Nile. There is a marked increase in the admissions of cases in the hospitals of the Asylums Board. It cannot be too plainly stated that no one is safe who has not been successfully revaccinated. Revaccination that does not take is a delusion and a snare. Let no one rely on Leicester impunity. The isolation of cases in this metropolis if ever practicable, is not so now. The turn of Leicester will come some day. Meantime, every unrevaccinated person is liable to an attack of the disease.

PUBLIC LAVATORY ACCOMMODATION.

PUBLIC LAVATORY accommodation for men and women has for many years been one of the most pressing wants of the metropolis. The want is admitted on all sides, but from various causes the provisions for meeting it have been, and still are, inadequate. It is satisfactory therefore to note that the vestry of Paddington have had the matter under consideration. So long ago as March, 1884, a special committee was appointed to consider and report as to whether lavatory accommodation could not be provided in such a way as to be a boon to the immediate vicinity in which it is placed, instead of being a nuisance, as must be the case more or less where structures for this purpose are erected in the centre of public thoroughfares. The area of Paddington alone is about 1280 acres, and in 1881 the population was 107,218, and yet but for private enterprise there would not be a public convenience in the whole parish, nor sanitary accommodation of any kind for women, except in connexion with the baths and wash-houses in the Queen's-road. On the 1st inst. the committee adopted a report for presentation to the vestry, in which they recommend that each licensed victualler should be called upon to provide proper and convenient accommodation, with suitable automatic flushing cistern; that better designed structures than those at present in use should be employed, each as far as possible being in charge of an attendant; and that two new underground public lavatories should be constructed. The subject is unquestionably one of considerable importance to the community, and should the suggestions of the committee be adopted *in toto* by the vestry, something at least will have been done to remove what is a great drawback to the comfort and health of the inhabitants of the metropolis.

THE PATENT MEDICINES STAMP ACT.

THAT the Chancellor of the Exchequer should have consented to a modification almost amounting to a repeal of the Patent Medicines Stamp Act is a subject for congratulation. The news will be received with feelings of pleasure by the public in general, and by the medical profession in particular. The stamp, we are told, will be so altered as to make it clear that it affords no guarantee of the genuineness of the preparation. Medicines are in future to be regarded as taxable only if proprietary. The term "proprietary" is somewhat vague and indefinite, and will be found difficult of definition, and still more difficult of application. We have occasion from time to time to call attention to special preparations of pharmacopœial and other drugs, which are introduced by chemists as being manufactured with exceptional care, and perhaps by some new process. The use of such remedies, which are neither secret nor patent, is a distinct benefit both to doctors and patients, and it would be most undesirable to hamper the progress of knowledge and discovery by taxing improvements. It would be better to substitute for the word proprietary the term "secret." With this exception the decision of the Chancellor of the Exchequer is all that could be desired. Secret remedies should undoubtedly be heavily taxed, for their use is a fruitful source of danger.

ATROPHY OF MUSCLES IN PLEURISY.

WHEN synovitis attacks a joint, the muscles which effect the movements of the articulation are prone to waste in a rather rapid manner. The muscular atrophy cannot reasonably be explained on the ground that the muscles are not used, for the atrophy is one which recalls the wasting of muscle seen in cases of infantile palsy, not only in the rapidity with which it occurs, but also in the behaviour of the affected muscles to electrical examination. The wasting of the muscles of the shoulder and thorax on that side which has been the seat of pleurisy seems to us to belong to the same category of phenomena as the wasting of muscle from joint disease; and although the comparison is a trite one, yet we may remember that serous and synovial membranes are regarded as analogous structures. The subject of muscular atrophy resulting from inflammation of tissues in the neighbourhood of the muscles is one deserving of much attention. The most probable explanation is that the abnormal excitations proceeding from the inflamed tissues along the sensory nerves have a direct influence on the motor nerve cells controlling the nutrition of the muscles concerned; the bones may waste as the result of a similar "reflex" influence. A valuable paper on the atrophy of muscles of the thorax and shoulder in pleurisy was contributed to the Société Médicale des Hôpitaux on April 10th (see the *Bulletins et Mémoires de la Société*, &c., April 22nd). The author of the paper, M. Desplats of Lille, contends that the muscular atrophy is rapid and frequent in the subjects of pleurisy, that the atrophy plays an important part in the deformities of the skeleton resulting from pleurisy, and that the atrophy is the indirect cause of tuberculosis of the lungs. He recommends that the atrophy should be prevented from coming on by early surgical treatment of any pleuritic effusion, and that measures should be adopted for arresting or combating the atrophy by the use of general and local stimulants, and more especially by faradisation, respiratory gymnastics, compressed air, and so forth.

THE DEATH OF PROFESSOR PANUM.

WE regret to have to record the death of Professor Panum of Copenhagen, the President of the last International Medical Congress. Professor Panum has for many years been known as one of the ablest workers in the field of medical and physiological science. His observations have been made largely in the field of scientific pathology, and he has left behind him many a mark in one of the most difficult fields of medical research. Panum exhaustively treated the subject of transfusion by physiological experiments, and in the work in which this subject was dealt with he gave an account of an elaborate series of experiments on artificial embolism of the various vessels of the body. He showed that fibrin is not necessary for resuscitation by transfusion, and that even with the greatest care it may act injuriously by clotting. His work on Embolism ranks with the classical writings of Virchow and O. Weber. Panum long ago worked at the nature of the virus of septicæmia, and came to the conclusion that it was independent of the agency of living organisms. His address on Food Rations for Man in States of Health and Disease, delivered at the International Medical Congress last year, contains valuable suggestions on the physiology of diet. Some of his latest work related to the formation of "physiological fistulæ" into the small intestine, with a view of studying the nature and properties of the intestinal juice uncontaminated with other secretions. The death of the Professor of Physiology of Copenhagen is a great loss to medical science.

FRACTURED RIBS AND SCURVY IN LUNATICS.

COMPLAINTS are made in the Russian medical press of intriguing and underhand behaviour on the part of the administrative body of the Odessa Hospital towards the medical staff. Relations seem to have been strained for several years past, for in 1879 the late Dr. Kleberg, who was principal medical officer, and his successor, Dr. Siljujanoff, both resigned their posts after a short tenure. Recently Dr. Grjasnoff, tired out by the vexatious and worrying treatment to which he was subjected, has also resigned. Dr. Andrusski, the chief of the lunatic department, has been hastily dismissed, most unjustly as it appears to the journal from which we quote, on account of fractured ribs having been found in the bodies of two of the patients who died. At the official investigation it was proved by the medical evidence that the bones in both cases were diseased, and might have been very easily broken by the pressure of the thorax on the edge of the bed. One patient had general paralysis and scurvy; the other chronic meningitis, pulmonary tuberculosis, Bright's disease, and scurvy, the whole osseous system, especially the ribs, being in both cases in a highly pathological condition. If the fractured ribs had anything at all to do with the death, it could only have somewhat accelerated the fatal issue of totally incurable diseases. Fractured ribs are sometimes found in the bodies of lunatics in this country, and explanations are usually offered depending upon the pathological condition of the osseous system of lunatics. But scurvy is not a frequent disease in English asylums. Surely the occurrence of two such cases should indicate to the Odessa hospital authorities the propriety of an investigation into the dietary scale to which the patients are subjected.

MEDICAL SOCIETY OF LONDON.

A LARGE and distinguished audience listened to the annual oration of the Medical Society of London, delivered by Professor Humphry, F.R.S., on Monday last. The oration, which will be found in full in another place, was frequently applauded. Sir Joseph Fayrer proposed, and Mr. Arthur E. Durham seconded, the vote of thanks which was heartily accorded to Professor Humphry. Dr. W. Miller Ord, the President, expressed the wish of the Society that the oration should be published in separate form. The conversazione was enlivened by the exhibition of many objects of interest, including water-colour drawings, wood-carvings, Japanese books and prints, old medical works from the library of the Society, autotypes, etchings and engravings, microtomes and microscopes, whilst the band discoursed the lively airs of many a well-known dance. It must be owned that with its annual dinner and conversazione the Medical Society of London serves in addition to its other functions, the useful and pleasing purpose of bringing together the diverse elements of which the medical profession is composed.

PHTHISIS IN THE ARMY.

THE mortality of soldiers from phthisis is just now attracting some attention, and has been the subject of many random statements. The Army Medical Report for 1882 gives the mortality from "tuberculous diseases" among the troops serving in the United Kingdom during that year "as equal to 2·00 per 1000 of the average strength, against a mean rate of 2·33 in the preceding three years. The *United Service Gazette* compares this rate among soldiers with the rate among the entire population of England and Wales, during the same year, which was 1·84 per 1000, adding that, having regard to the favourable sanitary conditions of the army, the rate should rather be compared with that prevailing in some of the healthy districts of England—for instance with 1·17 in Rutlandshire, 1·31 in Leicestershire, and 1·33 in Hertfordshire. Our contemporary admits that for exact statistical comparison these figures are open to criticism; the amount of fallacy involved, however, by such a comparison can lead to but one conclusion—namely, that no such comparison should have been made. The incidence of phthisis mortality upon males of different ages varies from 0·41 per 1000 between five and fifteen years to 4·12 between thirty-five and forty-five years. To compare, therefore, the mortality of soldiers from phthisis with that prevailing in the entire English population, male and female and at all ages, is worse than useless. The mean annual death-rate from phthisis among males in England and Wales aged from twenty to forty-five years during the ten years 1871 to 1880 was equal to 3·68 per 1000, which is not far short of double the rate that prevailed in 1882 among the soldiers serving in the United Kingdom. We are very far from asserting that the comparison of the death-rate of soldiers from phthisis with that of all males living at similar ages is by any means free from objection. If we accept the deaths from tubercular diseases in the army, as signifying the deaths from phthisis, there is still the source of error due to discharges on account of disease to be dealt with. On the other hand, we are scarcely inclined to accept our contemporary's favourable estimate of the healthy conditions of a soldier's life. Soldiers are in a certain sense selected men, but the habits of too large a proportion of our soldiers are, we fear, not unlikely to develop phthisical tendencies; and under present circumstances it would not be surprising to find them suffering from a death-rate from phthisis as high as the mean rate among males at the same ages in the general population. It is to be regretted that the statistics of the Army Medical Report are not sufficiently precise to render possible the calculation of the true death-rate from phthisis among soldiers, but we see nothing in the figures given to justify the alarm of the *United Service Gazette*.

STATE SANITARY SURVEY IN ILLINOIS.

THE Secretary of the Illinois State Board of Health has issued a circular, in which he points out that whenever cholera has prevailed as an epidemic in Europe it has eventually reached the United States, and has caused great havoc there. Until quite recently there was little or no sanitary organisation in Illinois, and this, coupled with the fact of the unrestricted immigration, places the State in a condition favourable to the reception of cholera. Under these circumstances, municipalities, communities, and individuals are urged to see that their surroundings are wholesome, and forms have been prepared with a view of facilitating the needed inspections on which the required action must be based. The survey proposed is different from the one now being undertaken in this country. Here, the inspectors of the State make cursory inspections with a view of stimulating local action; but in Illinois it is expected that the inspections shall be altogether carried out by local officers, and take the form of a house-to-house inspection. The forms on which the information acquired is to be filled in are extremely useful, and the preparation of a ground plan, with lines at intervals indicating a scale of feet, will be most helpful in enabling the local inspectors rapidly to draw trustworthy plans of houses and other premises. Dr. Rauch in his circular does not fail to point out that to which prominence has also been given by Dr. Buchanan in this country—namely, that even should cholera not reach the country to which the inspections relate, the work advocated will, if properly carried out, go far to save the State from many other diseases which are allied to cholera in so far as the conditions causing them are concerned.

STRANGULATED HERNIA.

AN inquest was held at Stockport on April 25th touching the death of a woman named Elizabeth Jackson, aged forty-two. From the evidence it appears that for some years deceased had suffered from an umbilical hernia, which had from time to time given her some trouble owing to its becoming obstructed. On April 11th Mr. Gardener, a graduate of the University of Bonn, practising at Portwood, was called in, and he continued in attendance until April 18th. On the latter day the woman was seen by Mr. Buist, assistant house-surgeon of the Stockport Infirmary, and this gentleman diagnosed strangulation of the rupture, and gave the patient "medicine which was intended to set the bowel at rest," as he did not think it safe to reduce it at that time. Death occurred on April 22nd, without relief to the symptoms, although Mr. Buist says he performed taxis *successfully on the Monday before the patient died.* At the inquest Mr. Buist seemed inclined to join issue with Mr. Gardener, both as regards the exact nature of the malady and its appropriate treatment. In the absence of any record of a post-mortem examination, it seems to us that there can be little doubt that the deceased had obstruction of the prolapsed bowel, and that this passed on to complete strangulation, for the history of the case relates what comes too frequently within the experience of hospital surgeons. We cannot quite understand why Mr. Buist should desire to censure Mr. Gardener for not recognising that the bowel was strangulated, as evidenced by the continued stercoraceous vomiting, and yet not take the steps to relieve that strangulation by the only rational means which he himself contended ought to have been adopted. Mr. Buist's own evidence and the questions he put to Mr. Gardener are inconsistent with one another. It may be, however, that we are not correctly informed on this head. One thing is certain, if the symptoms and signs were as manifest as they were described to be, neither medicine in the earlier, nor taxis in the later, stages was likely to avail much. It cannot be too strongly insisted on that the danger is not from operating too early, but not early enough. It is not altogether improbable that the taxis, as performed by Mr. Buist, was accompanied by rupture of softened gangrenous bowel, and that what appeared a satisfactory event was, in all truth, a fatal calamity. It is but just to Mr. Buist to say that he clearly recognised the condition of the patient; and further, that even had herniotomy been performed when he first saw the case, the prognosis would still have been grave to a degree. It may be useful here to draw attention to a fact of paramount importance—viz., that a hernia which for several hours has given rise to acute local and reflex symptoms should be subjected to the most careful examination and prompt efficient treatment. If we mistake not, many a student leaves our medical schools without having ever seen, from its incidence to its close, a case of acute strangulated hernia. This we mention, not by way of reproof, but with a hope that our hospital surgeons will endeavour, by all the means in their power, to give facilities to the general run of pupils to investigate for themselves the phenomena of hernia, and the accidents to which it is liable.

PUBLIC SCHOOL POLICE.

THE approval which greeted Sir William Harcourt's announcement in the House of Commons that he had directed an inquiry to be made by the Public Prosecutor into the fatal case of "bullying" at King's College was an expression of a very general mistrust in the management of our public schools. We have from time to time called attention in our columns to a growing dissatisfaction on the part of those most interested in the development of our public school system. The prospect of little boys of twelve years of age mingling freely with other boys of various ages up to eighteen or nineteen, often much to the injury, physically and morally, of all, is far from satisfactory. Parents scarcely at present realise the terrorism so aptly referred to by the Home Secretary which the bigger boys exercise over the smaller and weaker. We should be glad if we could think that the association of little boys with bigger had its worst phase in the exercise of "terrorism," for, unfortunately, we know too well that there is a "social evil" in this association which parents, as a rule, shrink from realising. It is only too well known in the medical profession that the ruin of many a little boy may be traced to the evil influences of immoral bigger boys. We know of no "social evil" which has been so unsuccessfully dealt with. Important as the suppression of "bullying" is, it sinks into insignificance in comparison with the larger question of the moral relations between big and little boys in unrestrained intercourse. The governing authorities of our schools, as a rule, meet three or four times a year. The most they do is to express approval or disapproval of some prominent subject brought under their notice by the head master. It is seldom that they are minutely acquainted with the working of the school. The more distinguished they are socially, the less useful are they as governors. It was once publicly remarked by the late Archbishop of Canterbury that his experience as school-master and governor taught him that the highest function of a school governor was to learn not to interfere with the head master. Thus the head master, in reality, becomes responsible for the educational, physical, social, and moral relations of the hundreds of boys committed to his charge. Many of these boys pass through his school, if a large one, scarcely known to him either in name or person. His influence over them is, in reality, very small. It rests chiefly with the assistant masters and tutors to guide boys aright; and their intercourse with them out of class, where most danger prevails, is very limited. It would be unreasonable to expect men worn out by six or eight hours' class work a day, to say nothing of the additional labour of looking over exercises and conducting correspondence, to discharge the duty of a kind of "police." Yet some system of school police is a growing necessity to keep in check the too free secret intercourse between big and little boys, and suppress the great "social evil" of our public schools.

EXCISION OF THE PYLORUS.

AT a recent meeting of the Hamburg Medical Society (*Deutsch Med. Woch.*, No. 17) Dr. Lauenstein reported a successful case of excision of the pylorus, and exhibited the patient, a sailor, thirty-four years of age. The portion removed, which was the seat of colloid cancer, measured eleven centimetres long, with a circumference at its gastric end of twenty-six centimetres. The patient was admitted into hospital on Dec. 20th, 1884, having suffered for several months from vomiting, and having lost about forty pounds weight. A moderately large, slightly mobile tumour was present in the epigastrium, but the stomach was not notably dilated. The stomach was thoroughly washed out before operating. The incision was made in the median line, and the pylorus, after being separated from the great and small omenta, was marked off from the duodenum, which was temporarily ligatured. Some adhesions of the posterior wall of the stomach were detached, and the segment extirpated according to the usual method. There was no disease of the glands in the vicinity. The abdominal cavity was closed after washing out with boracic solution, and the whole operation lasted two hours and a half. Recovery was rapid, and in about a fortnight solid food was given by the mouth. On the nineteenth day the patient had an attack of herpes, with fever and bronchial catarrh, but at the close of the third week he was able to leave his bed, and had an "enormous" appetite. The author remarked that during the past two years the results of this operation had been more favourable, and there was reason to hope that, by improvement in its method, a still greater reduction in the mortality would be attained.

THE LEWES LUNACY CASE.

WE entirely agree with Lord Coleridge that the so-called "examination" of Mr. Hillman was a farce. It is not, of course, for us to offer an opinion as to the *legality* of the examination conducted by the magistrates in this case. It may be that the Lord Chief Justice is wrong and that Sir James Hannen and Lord Justice Lindley are right. Perhaps the law may be satisfied by the fact of two magistrates looking into a carriage at an alleged lunatic already in custody, while he is actually on his way to an asylum, and after a couple of commonplace questions, such as "How are you?" signing an order for his consignment to the asylum, to which, as a matter of fact, he was then being forcibly taken. We say it *may* be that the law is satisfied with such a procedure; but if it be, we must be excused for adding, so much the worse for the law. We fail to see any difference, except in degree, between such a proceeding as that which took place in this case, and the fact of a judge—for convenience, to avoid taking a person out of the prison van—looking into that vehicle, and after asking the accused some ridiculous questions, sentencing him to prison and telling the coachman to drive on. If this is the way in which justice is to be administered, it ought to be generally understood. For ourselves, we can only say that anything more slipshod or ridiculous than this case throughout we cannot imagine. It is certainly high time a Lunacy Law Amendment Bill were passed; but this case ought to be a warning to the promoters of such a measure to see that provisions are incorporated to ensure that the justices, to whom so much more than has heretofore been left is to be now confided, may be compelled to discharge their duties efficiently. It must be assumed that no one does right, unless to leave right undone, not less than to do wrong, be illegal.

THE BUDGET.

WE must content ourselves with one or two plain criticisms of the proposals of the Chancellor of the Exchequer, leaving minute criticisms to financial authorities. First, we cannot but deplore that under a Ministry so professedly peaceful such an enormous Budget should have become necessary. No more striking proof could be afforded that statesmanship does not consist in passing mere Franchise and Ballot Bills, but in skilful recognition of the wide relations of the Empire and its corresponding risks. Next we must protest against the rough process by which the income-tax is applied to those whose income represents labour, and is precarious compared with those whose income is assured and arising from accumulated property. We approve of the higher taxation of spirits and beer. The amount of both of these articles consumed by the British public is disgraceful and disastrous, and any taxation which will reduce the amount will tend to diminish the disease and misery which come from drunkenness.

HEALTH OF CAVALRY HORSES.

The Report by Mr. Fleming, Principal Veterinary Surgeon to the Army, on the Health of the Horses serving in the United Kingdom during the year 1884, shows very satisfactory results. The average strength on the establishment was 12,054, the cases of disease and injury during the year were 7431, the deaths including horses destroyed were 207, and the number cast was 1272, being respectively in the proportion of 616 cases, 17·17 deaths, and 105·6 cast per 1000 of the strength. The sickness and mortality have been lower than in any of the three preceding years, and the casting lower than in any except 1881, when it amounted only to 93·8 per 1000. A striking feature in the returns is the almost complete absence of glanders and farcy, only one case of the former and none of the latter having occurred during the year. The case of glanders was in the 3rd Hussars at Hounslow, in which eight cases had occurred in the preceding year. Mr. Fleming remarks that "this is the last of the outbreak which took place in that regiment while it was stationed at Aldershot, the infection which led to the outbreak having been caught, in all likelihood, in billet stations in the East of London (where the disease always more or less prevails) while the regiment was on the march from Colchester to Aldershot in 1883." He apparently has forgotten that the disease "was contracted from an officer's charger which became infected at Alresford." The measures adopted in the army to stamp out this disease appear to have been attended with marked success. Accidents and injuries have been the most frequent cause of admission into the infirmary, and account for rather more than half of all the cases. Diseases of the digestive organs have been the most fatal class, enteritis being the most prominent disease, but those of the respiratory apparatus have been very nearly as fatal.

The most frequent cause of casting was old age, upwards of one-half of the cases being on that account; the average length of service of the horses so cast was thirteen years and a half. The highest proportion of admissions into the infirmary occurred among the four-year-old horses, a result probably of the number of new horses brought into the service at that age and of the consequent change of work and feeding. The death-rate was also highest among them and the five-year olds until the age of fifteen was reached, when it began to increase rapidly. There were 1274 horses purchased during the year at an average price, including expenses of journey, of £44 6*s.* 10*d.*, and there were 1189 cast and sold at an average of £11 5*s.* 2½*d.* We are glad to observe that Mr. Fleming has added to the value of his annual return by prefixing to it a report on several points which appear likely to be useful and instructive. We would suggest to him that an additional table, showing the average loss of time by sickness or injury—the mean daily sick of the horses,—would add much to the value of his returns. We sincerely congratulate him on the satisfactory state of the department over which he presides, as shown by the interesting tables in his report.

COCAINE IN EYE OPERATIONS IN ST. PETERSBURG.

Dr. Lange of St. Petersburg has extirpated two eyes under cocaine. He not only applied a 20 per cent. solution to the conjunctiva before the operation, but had it dropped on during the whole procedure. In one case complete anæsthesia was induced, the patient feeling no pain during the section of the ciliary or optic nerves. In the second case there was throughout considerable flinching on the part of the patient, due perhaps to mental reaction, as the eye preserved the power of vision, and was being removed for an injury. Dr. Lange has also performed an operation on the eyelids, applying previously an ointment of cocaine with vaseline, and after each cut a solution. The pain was very slight. The patient wished to have the other lid operated on without cocaine, but the suffering was so great that the drug had to be employed.

THE INTERNATIONAL INVENTIONS EXHIBITION.

On Monday last, at noon, the Inventions Exhibition, the third of the series held at South Kensington, was formally declared opened by the President, the Prince of Wales. The opening ceremony took place in the conservatory, in the presence of the Princess of Wales, the Princesses Louise, Victoria, and Maud of Wales, the Duke and Duchess of Edinburgh, Prince and Princess Christian, the Duke of Cambridge, and a large and distinguished company of visitors. Sir Frederick Bramwell, as Chairman of the Executive Council appointed to organise and carry out the Exhibition, welcomed his Royal Highness within its walls, and delivered an address briefly reporting upon the labours of the Council up to the time of opening. He publicly expressed to the contributors to the guarantee fund the sincere thanks of the Council, stating that, instead of £50,000 which had been contemplated as the amount that might be raised, more than £87,000 had now been guaranteed, and that this total is being augmented week by week. He pointed out that considerable additions had been made to the Exhibition buildings. Many small annexes had been swept away, and in their place spacious galleries had been erected. Not only had greater exhibiting space been thus obtained, but the gardens, which are so great a source of attraction to visitors, had actually been enlarged. He said that as the employment of electricity for the purposes of lighting was undoubtedly one of the most striking instances of the application of science to the purposes of daily life, special prominence had been given to the subject. The incandescent electric lamp was to be employed for the garden illumination in a manner and on a scale which, the executive believed, had never before been attempted. With regard to the "music" division of the Exhibition, he stated that, with a view of stimulating the love of music in this country, a series of choral and brass band competitions were being organised, and would be held in the Royal Albert Hall during the autumn. His Royal Highness, in his reply, expressed his wish that the efforts of the Council would be rewarded by a success as great as that which attended the previous two exhibitions. He then declared the Exhibition open. We think there can be little doubt that the Prince's wish will be fully gratified. Although much remains still to be done, there is ample evidence of the interesting and widely varied nature of the exhibits included in the divisions "Inventions" and "Music;" the latter will indeed probably render the illuminated gardens, already in themselves on a hot summer's evening sufficiently attractive, peculiarly appropriate and additionally popular, forming as it does one of the *raisons d'être* of the Exhibition. The subway from South Kensington Station is a decided success, and will not only add to the comfort of visitors, but will remove a source of annoyance to inhabitants of the district.

THE PREVENTION OF YELLOW FEVER.

Dr. Domingos Freire, in a recent communication to the *Rio News*, gives an account of the inoculations practised in Rio de Janeiro with the attenuated liquid culture as a prevention against the dangers of contracting yellow fever. From Dec. 22nd last up to March 22nd of the present year, 1109 persons of different nationalities, and whose ages ranged from one month to sixty years, were submitted to subcutaneous injections in the deltoid region of the arm with the said liquid. All, with the exception of one or two cases, experienced elevations of temperature, varying from 37½° C. to 40° C., frontal headache, pains in the articulations, general indisposition, and, in some, slight epigastric oppression,—symptoms which ceased after from twenty to forty hours, and without any medical intervention. In many cases these injections were practised in houses where, a few hours before, deaths had taken place from yellow fever; nevertheless in the cases specified, and under disadvantageous hygienic circumstances, not one single serious accident is said to have happened. Most of the inoculations were performed in the presence of the two medical men commissioned by the Spanish Government to specially study yellow fever in Brazil.

KINDNESS TO ANIMALS.

The celebration of May-day in London seems likely to take a new and very sensible form. It has long been the custom in some provincial towns, we believe, to hold an annual procession of cart-horses on May 1st, and this year the metropolis has made an effort in the same direction. We say an effort, because probably for want of organisation and publicity only about one hundred teams attended this May-day parade on the Thames Embankment. It is stated that there were no prizes, and therefore no competition; but each driver received an illuminated card commemorative of the gathering, acknowledging the evidence afforded of "care, attention, and kindness to animals." It is with this feature of the show that we are mainly concerned, and we trust that next year the idea may be carried out on a larger scale, and that prizes may be given to encourage kindness to animals. In this connexion we would repeat a suggestion we have already made, that prizes for kindness should be offered at the various cattle, horse, and agricultural shows throughout the kingdom. At Chobham, in Surrey, a prize of this sort, which is given annually, has been very successful. "Want of thought" is responsible for much evil, and such prizes would be the means of doing a great deal of good.

UNIVERSITY OF LONDON.

THE following important change in the examination for the degree of Doctor of Science is announced in the new Calendar of the London University:—The existing syllabus of the D.Sc. Examination with its division into sixteen branches is withdrawn. Any Bachelor of Science desiring to proceed to the degree of Doctor of Science shall be required to submit an original essay, dissertation, or thesis as the foundation of his qualification for the Doctorate. If the thesis be accepted, the candidate shall be examined upon the subject-matter thereof, and in such further cognate subjects as in the opinion of the examiners may appear necessary to test his knowledge of the branch of science which he professes. The examination for the degree of Doctor of Science shall take place annually within the first twenty-one days in June.

MEDICO-LEGAL ASPECTS OF THE LATE EXPLOSION AT THE ADMIRALTY.

THE conclusion which has been arrived at as to the position of the gentleman who was injured by the explosion is as follows. He was probably about to leave the office and had partly risen from his chair, placing his hands on the desk in front to assist himself, when, hearing a noise, he turned sharply to the left in the direction of the cupboard. The scalp wounds, all in the anterior part of the scalp, were in a line from before backwards, and from left to right. The large wound of the left conjunctiva, caused by a splinter, which was removed soon after the explosion, was from without inwards in the direction of the lacrymal bone, and was unaccompanied by wound or injury of the eyelids. The backs of both hands, also the inner side of the left and the outer side of the right, were dotted with grains of gunpowder; the scalp was extensively dotted in the same manner, chiefly over the left frontal region; the hair, eyebrows, and eyelashes were singed. The patient was found lying near the cupboard, with his head in that direction, and not towards the right in the direction of the force applied.

TRICHINOSIS IN ST. PETERSBURG.

A CASE of trichinosis has recently occurred in St. Petersburg. A gentleman named Von Bach and his guests were infected by ham. Altogether about twenty persons suffered. The occurrence has produced some alarm, and the trade in pig-meat has sensibly diminished. It is, however, gratifying to note that this seems to have been the only case of the kind occurring in St. Petersburg for some years past. The immunity is due to the establishment by the municipal council of institutions where pork and ham are carefully examined. The first of these was established in 1881, but was not very successful; as during the first five months only five carcases and 133 hams were offered for examination, notwithstanding the smallness of the fees charged and the certainty of an indemnity at market price in case trichinæ were found. In May, 1882, a different system was established, and during the next twelve months no less than 30,000 examinations took place, requiring the services of two veterinary surgeons and about a dozen assistants. Afterwards branch institutions were established, some of them by the traders themselves, and microscopical examinations systematically carried out. Last year there were examined 30,650 carcases, 2332 hams, 18 portions, and 11 wild boars. Those free from trichinæ are marked, all infected meat being destroyed. An interesting engraving of the chief institution is given in a Russian illustrated journal, in which a number of young women are represented seated at a table each with a microscope before her.

THE MEDWAY GUARDIANS AND THE LUNACY LAWS.

THE subject of the Lunacy Laws has been under discussion by the Medway Board of Guardians, who propose to memorialise the Local Government Board on the subject, suggesting that "all cases which come under the relieving officer's notice should be certified to by the medical officer and then removed to the workhouse for a period not exceeding fourteen days, when they could be taken before a magistrate who could order chronic harmless cases to the workhouse and others to the asylum." Dr. Buchanan said they had recently had a case in point. Mr. Athawes had to hold a court on Sunday to make an order for the removal of a woman to the asylum; this patient, until the recent decision, would have been temporarily removed to the workhouse. The woman had to be taken to the police-station and placed in a cell, after having attempted to strangle one of her children. Other parochial authorities also have had the matter under consideration, and the Whitechapel guardians have adopted a petition to the House of Lords on the subject.

MEDICAL MISSIONARIES.

WE learn from the *Church Missionary Intelligencer* that Dr. E. Downes has decided not to return to his former charge of the Mission Hospital in Kashmir. The committee accepted his resignation with regret, and placed on record their appreciation of his valuable services. They have recently accepted the offers of Mr. F. J. Harpur, B.A., M.B., B.Ch., of Trinity College, Dublin, and of Mr. Henry Martyn Sutton, M.R.C.S., L.R.C.P., L.S.A., for service as medical missionaries.

MILITIA SURGEONS.

WE would again draw the attention of the militia surgeons to the fact that Sir E. Wilmot's motion to refer their case to a Select Committee of the House is fixed for May 19th (Tuesday); and we would urge on every militia surgeon to use his influence to obtain members from both sides of the House to support the motion, which is not a party one.

THE municipal authorities of St. Petersburg and Moscow have had under consideration the measures to be adopted in case of the appearance of cholera. The St. Petersburg town council has given the town sanitary commission a credit amounting to 30,000 roubles for preventive measures, erection of cholera hospitals, &c. The Moscow council has voted 98,000 roubles for a similar purpose. Both the municipal councils have agreed to petition the treasury for assistance to the extent of 300,000 roubles in case a cholera epidemic should make a larger outlay requisite.

THE International Cholera Conference will open in Rome on the 15th inst., when it is expected that the delegates of the British and Indian Governments—namely, Sir W. Guyer Hunter, M.D., K.C.M.G., and Dr. Thorne Thorne on behalf of this country; and Sir Joseph Fayrer, M.D., K.C.S.I., and Surgeon-Major Timothy Lewis for the Indian Government—will be present.

THE Caucasian Medical Society has made Dr. Hoyer, Professor of Histology, Embryology, and Comparative Anatomy in the University of Warsaw, an honorary member in recognition of his services to science.

Dr. Diomede Pantaleoni, Senator of the Italian Kingdom, one of the leading members of the Academy of Medicine of Rome, and for many years a physician in high repute with the Anglo-American Colony in the city, died there, at an advanced age, on Sunday the 3rd inst. We hope to give next week some account of his career.

Acting on the suggestion of Mr. J. Mills, the inspector of cattle disease for Madras, the Government of India some time ago decided to test the efficacy of M. Pasteur's vaccine for the protection of animals against anthrax. From official papers recently published, it would seem that the results have been satisfactory.

By an advertisement in our present issue it will be seen that the courses of clinical lectures for the summer session, to be delivered at the Hospital for Sick Children, Great Ormond-street, by the physicians and surgeons of the institution, will be commenced next week.

At a meeting of the Cork County Club held last Monday, Dr. Charles Tanner, for his conduct during the recent visit of the Prince of Wales, was expelled from the membership of the Club. Ninety-one members voted, and of these eighty-nine were for his expulsion.

The Master of the Rolls has dismissed the appeal in the case of Hugall *v.* M‘Kean, an action brought against a landlord for an alleged breach of covenant to keep drains in good order, in which judgment for the defendant had been entered by Mr. Justice Wills.

A conference upon cholera was to meet at Berlin on Monday last, and Professor Pettenkofer was expected to attend. We have not yet received the reports of the meeting, at which, doubtless, Professor Koch will have detailed his recent researches.

The Italian Prime Minister has given an emphatic denial to the statement that there had been two cases of Asiatic cholera at Rome.

Dr. Robert Koch has been nominated Professor of Hygiene at the University of Berlin.

LUNATICS IN WORKHOUSES.

At a meeting of the Council of the Poor-law Medical Officers' Association, held at 3, Bolt-court, Fleet-street, on Tuesday, the 5th inst., certain of the clauses of the Lunacy Law Amendment Bill, now under consideration in the House of Lords, were passed in review, and considered in their bearing on the duties and interests of workhouse medical officers, especially Clause 10 and Sections 1 to 7. Sections 1, 2, and 3 provide that an alleged lunatic may be kept in a workhouse for fourteen days from its date by a certificate, containing the usual proviso, from the medical officer, and drawn according to Form 8 in the schedule. Section 4 provides that no person shall be detained in a workhouse as a lunatic for more than fourteen days, without an order under the hand of a justice of the peace having jurisdiction in the union where the workhouse is placed, which shall be drawn according to Form 9 in the schedule. The Council feel that this section will be found to be cumbrous and unworkable. Section 5 provides that the order is to be made on the application of the relieving officer, supported by a medical certificate according to Form 6 in the schedule under the hand of a duly qualified medical practitioner, *not being an officer of the workhouse*, and by the certificate under the hand of the medical officer of the workhouse drawn on Form 8 in the schedule. The Council holds that this is a gratuitous affront to and reflection on the medical officer, as he is to have the care and custody of the lunatic for fourteen days—it may be for more,—and then some medical man from outside is to step in, fill up the certificate, and be paid the fee, to the entire exclusion of the workhouse medical officer, who, in some workhouses, will sustain a very considerable diminution of the income he has hitherto derived from this source. Section 6 provides that when an alleged lunatic is in a workhouse, and the medical officer thereof has not signed such certificate as in this section is mentioned, or if at or before the expiration of fourteen days from the date of the certificate an order is not made under the hand of the justice for the detention of the lunatic in the workhouse, the medical officer shall give notice in writing to the relieving officer to take the requisite measures for the removal of the lunatic to an asylum; and by Section 7 it is decreed that, if he omits to give such notice, then for every day or part of a day he is in default he shall forfeit the sum of £10. It will be noticed that under the provisions of this clause every case, whether lunatic, idiot, or imbecile, now kept in the workhouse, must be notified by the medical officer, taken before a justice of the peace, and decided upon, not by the official, who knows all about him from daily observation, but by an absolute outsider, to the prejudice of the workhouse medical officer, and at an unnecessary cost to the guardians, who will be called on to pay a fee in each case; and as in many workhouses there are from 50 to 100 of such cases, the expense will be considerable. The Council feel that this Bill is framed in the harshest, most unjust, and most ungenerous spirit towards workhouse medical officers, and therefore earnestly calls on all such officers to use whatever influence they may possess to prevent this clause of the Bill from becoming law.

Signed on the part of the Council.

Joseph Rogers, Chairman,
May 6th, 1885. J. W. Barnes, Hon. Sec.

RUSSIAN OPINIONS ON ANTIPYRIN.

At a recent meeting of the St. Petersburg Medical Society, Dr. Grimm related a case of severe Erysipelas in which he used Antipyrin three times. The first time the remedy was successful and effected a cure in three hours; the second time no effect was produced; the third time, though nausea was produced, the cure was effectual. He gave a gramme three times hourly.—Dr. Barthel stated that in the clinical hospital generally five grammes were ordered (two, two, and one, at intervals of an hour), and with good results. Collapse had never been caused, and nausea but seldom; never vomiting or rigors on a rise of temperature.—Dr. Hinze confirmed this from his experience in a series of cases of erysipelas.—Dr. Moritz had used antipyrin largely both in the Clinical Hospital and in the Alexander Male Hospital. Besides typhus cases, where the remedy was not well borne, he had given it for three or four weeks in a case of acute joint rheumatism in which salicylic acid was useless; the quantity of antipyrin given was about four grammes per diem. The effects were prompt and satisfactory, reducing the fever with perspiration, without any nausea. It was worth remarking that intelligent patients observed that the taste of the remedy varied a good deal, so that the preparations were evidently not all alike. This might, perhaps, explain the different effects observed by Dr. Grimm in his case. Dr. Moritz had used antipyrin in pneumonia, but could not say that the course of this disease was shortened by its means.—Dr. Börling had seen antipyrin used in Strasburg in typhus and pneumonia, and had employed it himself in private practice with good results, especially in a case of abdominal typhus in a child of five years of age. The temperature fell after the first series of three doses (double as many grains as the child's age in years, so in this case ten grains). After the second series it fell to 36·5°, and remained for two days below 38°. As soon as it rose to 39° the antipyrin was again given. The illness lasted about three weeks. The child recovered. Dr. Börling generally gave the drug in syrup, and found children liked it in this way. —Dr. von Grünewald had used antipyrin often, but had several times seen vomiting produced.—Dr. Hüber confirmed Dr. Moritz's observation that antipyrin, like other antipyretic remedies, though capable of reducing temperature in a longer or shorter time, did not shorten the course of diseases.

OUR WAR CORRESPONDENT'S EXPERIENCES IN THE SOUDAN.

(Concluded from page 818.)

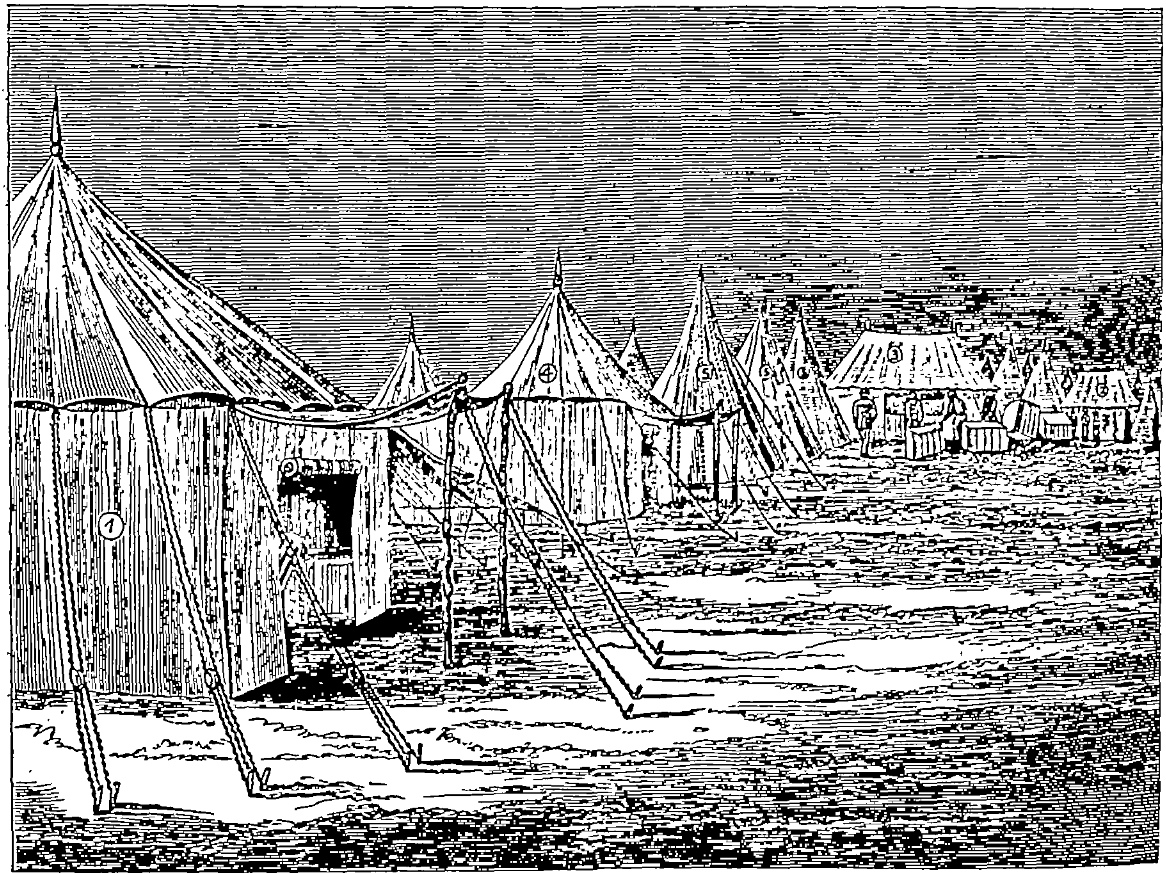
THE days a correspondent spends out in the Soudan are by no means dull. There are few hours, indeed, in which a man keen for inquiry cannot somehow or other find material in which to interest himself, or those on whose behalf he is acting. A visit to the town of Sawakin on one occasion—a sort of by-day—repaid me well for the trouble in doing so. It had been blowing strongly from the N.N.W. since daylight on the date in question, and raising such a dust-storm over the plain, camp, and shipping in harbour that everything a few yards distant was periodically quite hidden from view, and military movements had in consequence to be suspended for a time, whilst those who were on shore, and were unfortunate enough to be living in tents on the border of this extensive sand desert, had not only their nostrils, eyes, and ears filled with fine gritty particles of sand, but their hands were kept pretty busy in brushing off the yellow-coloured dust from articles of diet, as well as that quantity that had collected to the depth of half an inch or more on their bedsteads, their seats, accoutrements and saddles, and other tent belongings. To the poor sick and wounded this dust-storm proved irksome and distressing to a degree. Towards four o'clock, however, on the wind lessening in force and shifting more easterly, a subsidence of the disagreeables took place. People then could both see and breathe better than they could an hour earlier, and by five o'clock, with a little extra brushing up, matters had smoothed a bit and settled down to their normal condition.

Mr. Walter Truscott, the energetic representative of the *Pictorial World*, and myself, in company, determined to pay the Arabian quarters in the town of Sawakin a visit, and landing in the cool of the afternoon close to a large building now in the possession of and occupied by a number of our marines, we went in search of some of the lions of this town. Now, to judge by the numbers of friendly Arabs we met in passing from street to street (if these irregular and tortuous by-ways deserve such an appellation), as well as the unmolested character of our peregrinations, one could scarcely realise that at that very moment perhaps a desperate fight was being waged, and not very far off either, between our troops and these lithe-limbed fellows' kinsmen. Moreover, on passing from store to store, from stall to stall, and seeing the brisk business carried on by the squatting, cross-legged date-sellers, the jabbering fish-vendors, &c., it was evident to me that there were at least some sensible followers of Mahomet who did not up to the present believe in the glory of war, and that there was yet a remnant of the true believers of the Koran who, in fear and trembling of our powerful display of an armed force, had not deemed it desirable to quit their customary occupation and join their fathers, their brothers, or relatives in yonder plain. We observed two or three drinking dens, bearing French titles, "Hôtel de Ville," "Hôtel de Lesseps"; they were not sufficiently inviting, however, in their exterior to tempt us, so we did not enter them. On walking through a sort of main street lined on either side with rows of dirty-looking shops in which Arab merchants and dusky-coloured craftsmen were exposing their offensive-smelling fish and fly-covered merchandise and wares for sale, we arrived at a sort of square filled with human beings collected from every nation under heaven, and on the further side of which stood quite a handsome-looking edifice, built of quadrangular blocks hewn out of white coral brainstone (all the buildings and all the walls in this town are composed of this beautiful coralline substance), and which the bystanders asserted to be

OSMAN DIGNA'S TOWN HOUSE.

Of course Truscott would sketch the inside, whilst I determined to try my hand at the outside of the mansion—, that is to say, if the tenants now in possession of it would grant us permission, and let us enter to do so. So, wending our way through the motley ill-conditioned crowd, we arrived opposite the solidly built double front door, one-half of which happening fortunately to be just open, we cautiously peeped in, intending to beat a hasty retreat if circumstances necessitated our doing so, and saw at once that the badly lighted room was occupied by some four or five elderly Arabs, disposed variously round the apartment. One of them, by far the youngest of the party, clad in a sort of white linen vestment, on his knees and bowing his head repeatedly to the ground, was evidently in a posture of religious supplication,—no doubt fervently imploring the favour and assistance of Allah against us all as the unwarrantable intruders upon and the spoilers of their land. Waiting a minute or two for him to rise from the posture of devotion, we advanced a step, and with one foot on the door-sill salaamed as well and decorously as we could in the ordinary mode of Eastern salutation—of course having practised it somewhat beforehand,—and to our great surprise and unspeakable delight were not only welcomed inside, but offered an inspection of the whole of this dwelling. Beyond the basement hall (the upper and other rooms being cramped and small), there was little to note or write about; so on returning to Osman Digna's reception-chamber, Truscott up with his sketching stool, out with his block, and commenced operations forthwith. I took up a position just in rear of my colleague, with a view to notice what the Arabs were about, and see how they would act under this palpable breach of etiquette on our parts, as well as to throw in a suggestion or give him an artistic hint now and then as the process of his sketching went along. The knight of the pencil had not, however, been long at his work before our religious friend threw off some of his reserve, came boldly up to our side, and when he saw what was being done by Truscott actually smiled—by Jove! it is not often that an Arab smiles,—and after muttering some unintelligible words to his friends squatting and conversing together on the other side of the room, he proceeded to open a cupboard in the wall and withdrew therefrom vestments of the most elaborate as well as costly description. Divesting himself of his toga alba he quickly assumed another of a widely different character both as to colour and textile condition. First of all came a light azure-blue-coloured and flowing satin skirt; and, gathering in its ample folds, he next encircled his slight waist with a cream-coloured girdle of twisted silk; then over his sloping shoulders, carelessly, still very artistically, was thrown a bright-golden-coloured ribbed-silk shawl from which hung fringe of the same quality at least six inches deep. After this appeared on his head a huge turban of rich yellow and maroon silk, and then, with a glance in a small hand-mirror which he held and a twist or two of his jet black moustache, he finished his get-up, evidently much to his own as well as to his companions' satisfaction. Truscott stopped work to look in astonishment at this modern example of an Arabian Nights transformation, whilst I was equally lost in *amazement* at the wonderful change that had come over the religious devotee since the first moments of our self-forced introduction.

H REDOUBT AND BASE HOSPITAL.



1. Dr. Trotter's tent. 2. Hospital stores tent. 3. Operating tent. 4. Medical officers' tent. 5, 5, 5. Tents of orderlies and attendants.

Subsequently it transpired we had (quite by accident) hit upon the day of the sheikh's "at home," as several elderly white-headed old patriarchs called upon him during the afternoon of our visit, giving him most deferential bows on entry, and receiving from him in turn that *bonhomie* courtesy which alone is the outcome of position, patronage, and power. A question now naturally arose betwixt us,

"WHO IS HE,

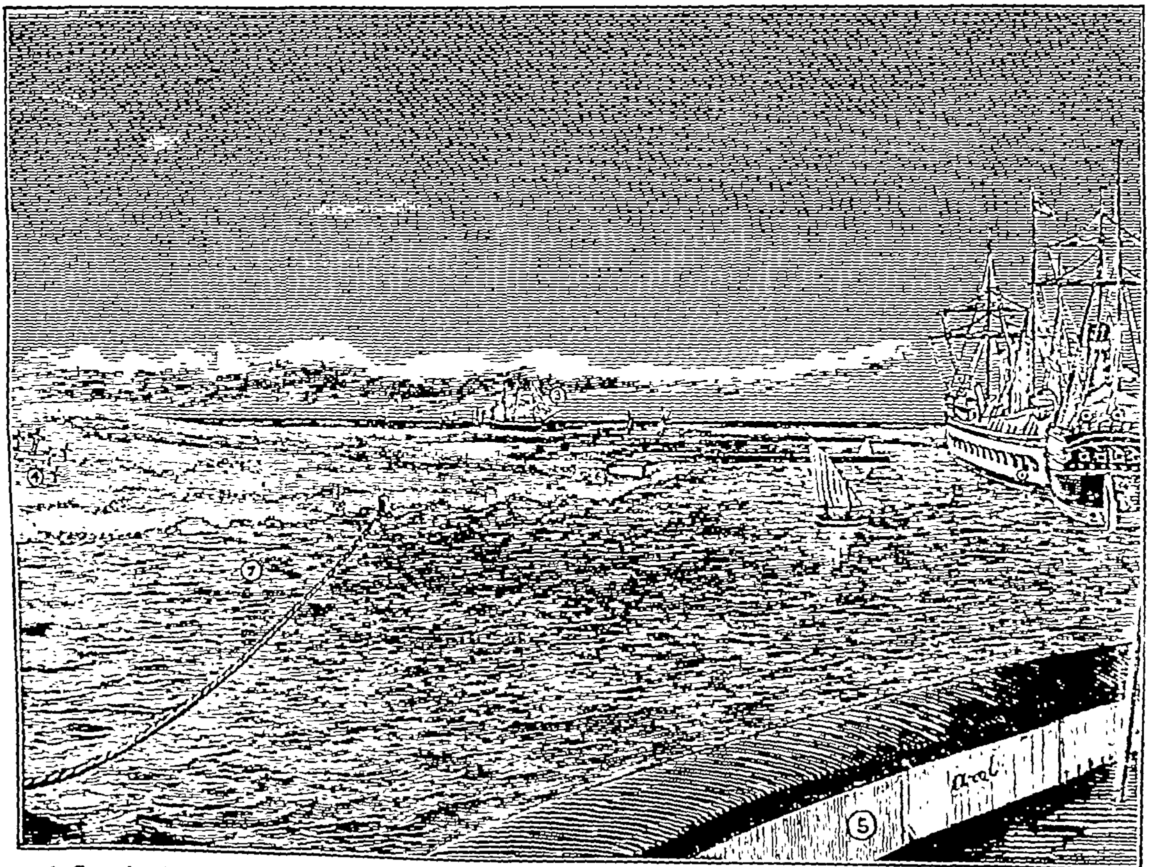
as a respected tenant in this Osman Digna's house?" "Is he a brother, is he a cousin, or in what relationship, if any, does he stand to that Mahdi's lieutenant, who has so long and so pluckily defied the British arms and power?" How we longed to know how and by what means the present holder had been permitted to remain in occupation of this domicile! But any further surmises on our part were suddenly cut short by the introduction of coffee, which, in small chased silver cups, was handed round by an attendant to all present. On the same being presented to me I incautiously proceeded to tip the Nubian slavey, and received a well-merited rebuke from mine host for my thoughtlessness and want of manners on this occasion. With some degree of diffidence I brought the tiny metallic receptacle to my parched lips. I was very thirsty at the time, and swallowed an ounce or two of the strongest infusion of Mocha I ever tasted in my life; and although the dictates of conventionalism amongst the Arabs forbid a guest to reject proffers of edibles or drinkables not actually forbidden by their religious tenets, I think I must have refused a second edition of the coffee—"thick stuff" Truscott called it—if brought round again, and was very glad to find there was no repetition of the courtesy. I was wearing at the time a brown leather cross-belt, to which was attached a cartouch-box for carrying a small surgical case in. To-day within it there happened to be a consignment of cigars. A thought struck me. I'll offer my guest one of them. So, bringing the box round from my back, I was in the act of undoing it for the purpose of extracting a veritable "Henry Clay," when I saw a look of consternation on the face of my host and his other native guests. I grasped the situation in a moment. They thought I carried firearms, and was going to use the same against them. It took but a moment to undeceive them, for in a second or two afterwards a cigar was out from where a cartridge was expected to issue, and presented with due formality to His Excellency, while I explained to him at the same time that I was not a fighting man. My business out in the Soudan, and amongst his people, partook more of a pacific than a fighting character, and my desire was for peace rather than war. I assured him I had never lifted hand or weapon against him or his people, and, more than that, I trusted I never should. This explanation gave him confidence, and the fear formerly depicted on the countenance of my host was speedily changed to a look of astonishment, whilst a considerable amount of amusement was created amongst the guests present by the *dénouement* to which my cigar-case had so unexpectedly given rise to. He gracefully declined my offer, saying he never smoked; but from that moment I was always a welcome guest at the house. I should scarcely deem the above incident worth recording were it not for

WHAT CAME OF IT AFTERWARDS.

Two or three days elapsed before I again paid the town a visit; when I did so I called in to see my sheikh friend, and was welcomed more cordially than before. Presently an elderly Arab entered and commenced a very animated conversation with mine host. I listened—who will blame me for doing so?—and through possessing a slight knowledge of Persian and Arabic, gained during my studies in the Hindustani language, and from carefully watching the manual demonstrations by the informant, putting this fragment and that fragment of conversation together, I was enabled to gather that not only had something unusual happened amongst their Arab forces, but, if I mistook not his meaning, a sad fatality had overtaken the Amara and Samara tribes by some fatal blunder—i.e., they had been mistaken, it appeared, in the smoke for English soldiers, and by getting between the fire of our troops and the riflemen on Osman Digna's side had lost nearly a thousand of their number by their stupidity and blundering. This was indeed a most welcome "find" for me. A thought at once struck me: "That old fellow knows more than he has told; I'll try to get hold of him for further information." With this idea in view I set to work, and within a few hours he was attendant on me in one of Messrs. Lucas and Aird's tents, and a willing agent in my service into the bargain. I proceed to give the dialogue *verbatim* as it occurred between us in the presence of one of the ablest interpreters attached to the British camp.

ENTRANCE OF SAWAKIN HARBOUR.

(*Sketched from the deck of the steam transport ship "Arab."*)



1. *Ganges* hospital ship.
2. R.I. steam transport ship *Bulimba*, Captain Clark, R.N.R.
3. H.M. gunboat lying at entrance of harbour.
4. Old burial-ground, where the late Lt. Dallston, of the Guards, lies.
5. Rail and bulwarks of *Arab*.
6. Henhouse of *Ganges*.
7. Showing shallowness of water over coral formation.

Q. What is your name? *A.* Al-Abed.—*Q.* What countryman are you? *A.* Arab by birth.—*Q.* Where do you live? *A.* Principally at Jeddah.—*Q.* How is it that you are here in Sawakin? *A.* I am a travelling merchant sheikh, and have been so for a number of years.—*Q.* Do you know Osman Digna? *A.* I do, very well indeed.—*Q.* Now, are you friendly with the English? *A.* Yes, quite so; I do not think the English will do me any harm.—*Q.* How is it that Osman Digna and your brethren in arms do not think so too, and come in and be making money by working on the rail as the friendly disposed are doing? *A.* Because they are silly men, and do not know better.—*Q.* Now tell me, have you heard that any of Osman Digna's troops have been killed through an accident? *A.* I do know it to be perfectly true that several hundred men of the Amara and Samara tribes were shot by getting in between the fire of the English and our men.—*Q.* Is there any dissatisfaction amongst Osman Digna's party? *A.* Yes, there is considerable disapproval amongst them at being forced to fight outside when many of their friends are staying inside the town not fighting, and earning plenty of rupees by so doing.—*Q.* What is your opinion about Osman Digna's surrendering himself to the British, and upon what terms? *A.* On account of the many people leaving him, I think it highly probable Osman Digna would surrender himself on certain terms being granted him.—*Q.* Give me your ideas of his terms, and I will see what can be done for you. *A.* First, the lives of himself and all followers must be spared; secondly, that he on surrender be treated as a patriot, not as a rebel, and *with no less consideration than Arabi was;* thirdly, that work be found on the railway for the people when they do come in and lay down their arms.—*Q.* Could you carry to, and bring back a letter from, Osman Digna? *A.* No, not myself, I am too old for the journey; but I can get a man to do it, if the General will grant a pass through the British lines, and the messenger is paid for going. — *Q.* Where is Osman? *A.* I cannot tell you. It would cost me my life.

And with this our interview terminated. Then getting the principal items of our conversation jotted down and signed by the interpreter present as a witness to its veracity, I posted off with it to the tent of General Ewart at the base, who took such a well-disposed interest in the matter that he at once despatched me in company with his aide-de-camp to head-quarters, so that the officer in charge of the Intelligence Department should be made aware of the facts without a moment's delay. What transpired between myself and Major Grover for the purposes of this paper need not be known; but the public may rest assured that no stone has yet been, nor ever will be, left unturned to bring about a pacific as well as an honourable termination of this most calamitous campaign. This happened on Saturday, March 21st. Sunday followed with all its train of distressing and disastrous events. Who knows by the sparing of our troops from that Sunday's march out what might by God's mercy have been brought about? I never saw my sheikh friend again; so turning my thoughts from our friendly Arabs (for there are many such) and casting my eyes plainward, what a ghastly sickening spectacle of war lies there! Upwards of twenty heaps, each one containing about a hundred carcases of human beings just ready for burial or cremation, as the urgency of the circumstances may demand. On beholding such an unnatural exhibition, what is the exclamation that escapes the lips of every officer and every man you meet with out there?—Horrible! And is it not also asked everywhere you go—

FOR WHAT PURPOSE IS ALL THIS EXPENDITURE OF HUMAN LIFE?

Ah! we may well ask ourselves that question. All to whom I have spoken on this subject feel that whilst brave and heroic Gordon lived, while there remained the remotest possibility of rescuing the devoted garrison under his command, there was at least an excuse, and a very just excuse too, for saving them all, even at the expense of the most daring chivalry the bravest and best army England could command; but now he has gone, died a hero's death, and his fondly attached followers all been either butchered or scattered to the four winds of heaven, surely the cause has virtually ceased to exist, precious time having been wasted, and the opportunity been lost—ay, for ever and ever—for doing any more than sacrificing men and treasure in this sickly sun-scorched land. As I, in the painful execution of that duty imposed upon me, look upon the heart-rending scenes of carnage and bloodshed strewn around, as I see the bodies of those poor fellows, with their arms, legs, and heads pointing in all directions, lying huddled together in putrescent heaps, as I think of the hundreds made widows, and the thousands rendered fatherless, or contemplate the scores of friends and relatives who will never welcome back the return, or see the kind face of a brave husband, father, or loving friend again; as I see the seething and devouring flames wrapping round, one after another, the poor, yet after all perhaps the happiest of happy homes, of these poor barbarians, and as I view the smoke of that desolation circling and curling upward to the sky,—I can but think that if there be a God in heaven he will surely bring some to book who have been foremost in fomenting and urging on this most unholy of wars. I turn from this spectacle homeward, and arriving once more at the Base Hospital, my attention is called by the surgeon in charge to a very interesting case, indeed, it being that of

A POOR ARAB LAD SHOT THROUGH BOTH THIGHS.

On my entry into the hospital tent he was observed lying on his left side, and certainly appeared not more than thirteen, or at most fourteen, years of age. He is recognised as one of the brave leaders who made a most plucky and determined attack on our lines, for, with nothing but a banner in hand, he rushed on our ranks, utterly regardless of life or the consequences, until he was brought to earth, being shot through both legs by one of our marksmen. With the same determination, however, and the same patience as he exhibited during the fight, in the presence of his captors he bore his pain and sufferings now, and they must have been excruciating at times. Although the bullet had penetrated and passed through the fleshy part at the juncture of the middle and upper thirds of both limbs, I never even heard him moan; not a cry, not a groan, ever escaped his parched and swollen lips, and there was little to tell, beyond the visible application of a quantity of antiseptic dressing wrapped round the limbs, that he had ever been wounded at all. Poor fellow, he lay so quiet—never moving, save to brush away occasionally some irritating fly that had settled on his fever-heated brow; but never would he let it be known that he felt pain, or that he suffered any inconvenience whatever from the active and plucky show he had made in yonder fight. Now and then he would try to, and did, remove the dressings and bandages from his extremities, and it kept the nursing staff pretty busy preventing him from oftener repeating the offence.

I think in my last letter I spoke of the ship *Ganges* being suitably painted white; why I did so is because most of the transports are painted of a slate-grey colour, for what purpose I am at a loss to conjecture, when, for all purposes of health or mitigating the effects of heat, these vessels might as well have been clothed in a darker colour. From experiments made by myself and others, most carefully conducted by a naval officer some time ago in Bombay dockyard, it appears that a very great mistake is made in coating ships of a hue anything approaching an ash-grey tint.

I append the results of these experiments to prove the accuracy of my statements, with the view that some interest may be awakened in those who are responsible for the transport arrangements, and have the interest as well as the health of our soldiers and sailors at heart.

My experiences in the Soudan are now drawing to a close, as having been offered by the Principal Medical Officer at the base, and accepted, a charge, in conjunction with another medical officer, of some sick and wounded bound to Suez, I proceed on board the *Deccan* to take up my duties before night has finally closed in.

Already one of my rough sketches—that of the battle fought at McNeill's Zereba on the 22nd ult.—has been kindly accepted by the proprietors of the *Illustrated London News*, and appeared in the front page of that famous weekly. In the pages of THE LANCET to-day appear copies of two others, one showing the entrance proper to Sawakin harbour, with the *Ganges* and *Bulimba* lying at their moorings, and burial-ground, and sketched from the deck of the *Arab*, on board of which vessel I was most courteously supplied with quarters by Captain Fellows, R.N.; the other representing the tents of the Base Hospital, particularly that belonging to Surgeon-Major Trotter, shown in the foreground, to whom I am indebted for much valuable information during my stay at Sawakin and the front.

EXPERIMENTS.

No. 1. Made on March 18th, about 2 P.M.; temperature in the shade at the time being 85° F. The bulb of a thermometer was held against the side of the naval transport Union Co.'s ship *Arab;* the thermometer during the experiment being screened from the sun by a handkerchief.

Result.

Temp. of air in shade	85° F.
„ „ against black part of iron hull	113°
„ „ against a portion painted white ...	104°
„ „ against a portion painted lead-colour	112°

No. 2. In a wooden box, painted black, a thermometer was introduced, and also into another painted white (both left standing for one hour in the sun). The result was as follows:

1. Black ... ... 117° F. | 2. White ... ... 102° F.

No. 3. Six thermometers I hung up in the sun, having two parts of new bunting of different colours wrapped round the bulbs and lower ends of each thermometer (also exposed to the sun for one hour).

Result.

Temp. of the air in shade	91° F.
„ 1st thermom. cov. with 2 parts of white ...	106°
„ „ „ „ yellow ...	109½°
„ „ „ „ red ...	110°
„ „ „ „ blue ...	114°
„ „ „ „ light-blue	115°
„ „ „ „ black ...	117°

This experiment shows the advantage of light-coloured clothing and awnings in the tropics. Having no lead-coloured bunting, I was unable to test results with this.

No. 4. Procured ten tin biscuit-boxes, and painted them variously as under. *Into each one was introduced* a thermometer, which was simply left standing up in the boxes on the side opposite that exposed to the sun. Time, 3 P.M. Temperature of external air in the shade, 88° F.

1. White	100° F.	6. French-grey...	106½° F.
2. Yellow	103½°	7. Lead-colour ...	109°
3. Red	104°	8. Dark-green ...	110½°
4. Stone-colour ...	102½°	9. Light-green ...	109°
5. Blue	106°	10. Black	114°

N.B. These tin biscuit-boxes were closed, and left standing in the sun for about two hours.

No. 5. Three square tin biscuit-boxes were next painted and whitewashed variously, to test the relative merits of same.

Results.

A*a*.	Painted white, and exposed to the full rays of the sun	100° F.
	Painted French-grey, and exposed to the full rays of the sun	111°
	Painted dark-grey, and exposed to the full rays of the sun	112°
A.	Painted with one coating of grey over white	108°
	Painted with two coatings of grey over white	116°
	Painted white, and exposed to the sun ...	100°
	Whitewashed	98½°
B.	Biscuit-box, painted French-grey	111°
	Over this paint one coating of whitewash applied	102°
	With two coatings of whitewash	96°
C.	Biscuit-box, painted lead-colour	112°
	Over this paint one coating of whitewash applied	103°
	With two coatings of whitewash	97°.

The results of these experiments go far to prove the vast superiority of white to *grey* as regards coolness for coating anything that is subject to exposure to the sun in the tropics, and would also lead to the inference that white, if allowed to become dirty or grey-like, would thereby be rendered much less cool than it originally was when in a cleanly condition. Moreover, the results of experiments carefully and patiently made by Staff Commander Pounds, R.N., of Malta Dockyard, go very far to corroborate in every respect those of my own.

Erratum.—In our correspondent's letter published last week, an important typographical error escaped correction. Each of the officers' hospital tents is there stated to have contained "eighty" beds. The number should, of course, have been eight.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Poplar.—In the last monthly report issued as to the Board of Works for the Poplar District, reference is made to the visit of Dr. de Chaumont, on behalf of the Local Government Board, in connexion with precautions which may be necessary as to cholera. From what is said, it would appear that the central authority are advising all port and riparian authorities to be provided beforehand with means for isolating cases of that disease; and that it has been laid down as desirable that cholera cases should not be subjected to a journey of more than a mile when isolation is intended. For the metropolis this would mean the establishment of a large number of hospitals; but, having regard to the symptoms of cholera and their rapid progress, we believe the limit of one mile to be a wise one; and should the disease appear in our midst we hope the requisite number of temporary hospitals will be forthcoming.

Huddersfield (Urban).—A report issued by Dr. Cameron shows that the death-rate in Huddersfield during the thirteen weeks ending April 4th was equal to 22·4 per 1000, of which 2·0 was due to the principal zymotic diseases. Both those rates were slightly below the mean rates during the same period in the twenty-eight English towns, although they somewhat exceeded the low rates that prevailed in Huddersfield in the first quarter of 1884. The deaths last quarter included 36 from measles; and Dr. Cameron points out that little can be done to check the spread of this disease until it is added to the list of diseases to be notified to the sanitary authority. It is pointed out, moreover, that 4 deaths were referred to typhoid fever, and that 19 "supposed" cases of this disease were notified during the quarter, suggesting the probability of another outbreak of this disease next autumn unless preventive measures are vigorously enforced. Infant mortality in Huddersfield last quarter exceeded the average rate in the twenty-eight towns, owing in great measure to the epidemic prevalence of measles.

Stretford (Urban).—The report upon the sanitary condition of this suburban district of Manchester during 1884 states that the birth-rate and death-rate were equal to 27·5 and 17·3 per 1000 respectively. The estimate of population upon which these rates are calculated is, however, omitted, which materially detracts from the value of the rates. The population of this district increased from 11,945 in 1871 to 19,018 in 1881, and Mr. Pettinger appears to have estimated the population in 1884 at 20,000. This is considerably below what the estimate would be if based upon the rate of increase between 1871 and 1881. The death-rate given (17·3) exceeds that recorded in recent years, and no account appears to be taken of the deaths of residents recorded in public institutions situated outside the district. With regard to child mortality, we are told that the deaths included 139 children under five years, "showing a death-rate of 6·95 children under five years of age." It may be presumed that this means that the deaths under five years were equal to 6·95 per 1000 of the population at all ages. Such a rate is utterly valueless as a test of child mortality, which can only be measured by the proportion of deaths of children to the number of children living at the same ages. We are not told that the deaths of infants under one year were equal to 144 per 1000 of the children born, which is a trustworthy test, and shows for such a district as Stretford a remarkably high rate of infant mortality. The zymotic death-rate is given as 1·9 per 1000, and was mainly due to 9 deaths from scarlet fever and 24 from diarrhœa. Bearing in mind the suburban character of the population, and its large quota of domestic servants, the sanitary condition of the district, in spite of a comparatively low death-rate, cannot be considered satisfactory.

New Windsor (Urban).—Dr. Casey is able to report very favourably of the health of this municipal borough during 1884, the death-rate having been but 13·3 per 1000, which is satisfactorily low, even after due allowance for the abnormal character of the population, including as it does a large proportion of soldiers. The population of the borough is estimated (evidently on the basis of the rate of increase between 1871 and 1881) at 12,441. The birth-rate was not more than 26·8, influenced, as was the death-rate, by the number of soldiers and of domestic servants in the population. The deaths, including those in the union workhouse, and excluding those of *non-residents in* the Royal Infirmary, were fewer than in any recent year, and were 74 below the number that would have occurred had the rate in the borough been equal to the mean rate in the whole of England and Wales. Two exceedingly favourable features in this report are: (1) the low rate of infant mortality, which was only 72 per 1000, and less than half the general rate; and (2) the low zymotic death-rate, which did not exceed 0·88 per 1000. The statistical part of the report, especially that which gives the rate of mortality during the past five years at each of four groups of ages, is highly commendable, and corroborates the satisfactory evidence of the low death-rate at all ages. Two unfavourable features in the report should, however, be noted. It is stated that no means exist in the borough for the isolation of cases of infectious disease, which, in view of the four cases of small-pox that occurred last year, cannot be considered satisfactory. It appears, moreover, that the town, especially in the older parts, abounds with "dangerously polluted wells." The favourable mortality statistics of last year should not depreciate the value of the warning implied by Dr. Casey in pointing out these defects in the sanitary condition of the Royal borough.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5792 births and 3601 deaths were registered during the week ending the 2nd inst. The annual death-rate in these towns, which in the preceding two weeks had been 23·2 and 23·4 per 1000, declined last week to 21·1. During the first four weeks of the current quarter the death-rate in these towns averaged 23·2 per 1000, against 23·9 in the corresponding periods of the nine years 1876–84. The lowest rates in these towns last week were 15·1 in Hull, 15·1 in Derby, 15·2 in Bolton, and 15·9 in Brighton. In the other towns the rates ranged upwards to 30·1 in Blackburn, 30·6 in Manchester, 32·7 in Preston, and 34·4 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding nine weeks from 377 to 529, declined last week to 449; of these, 176 resulted from measles, 127 from whooping-cough, 36 from small-pox, 33 from scarlet fever, 30 from diarrhœa, 20 from diphtheria, and 22 from "fever," principally enteric. The lowest death-rates last week from these diseases were recorded in Brighton and Derby, and the highest in Sunderland, Cardiff, and Newcastle-upon-Tyne. Measles caused the highest proportional fatality in Sunderland, Liverpool, Manchester, and Cardiff; whooping-cough in Blackburn, Cardiff, and Preston; scarlet fever in Preston, Newcastle-upon-Tyne, and Sunderland; and "fever" in Norwich and Leicester. Of the 25 deaths from diphtheria in the twenty-eight towns 15 occurred in London, 3 in Bristol, 2 in Portsmouth, and 2 in Liverpool. Small-pox caused 66 deaths in London and its outer ring of suburban districts, 2 in Manchester, 1 in Liverpool, and 1 in Halifax. The number of small-pox patients in the metropolitan asylums hospitals, which had been 1062 and 1034 at the end of the preceding two weeks, rose to 1282 on Saturday last; the admissions, which in the previous two weeks had been 307 and 246, rose to 354 last week, and exceeded the number in any week since June last. The Highgate Small-pox Hospital contained 87 patients on Saturday last, 20 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding three weeks from 512 to 381, further fell last week to 337, and were 59 below the corrected weekly average. The causes of 91, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Plymouth, Nottingham, and in three smaller towns. The largest proportions of uncertified deaths were recorded in Hull, Halifax, Salford, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the preceding four weeks had declined from 25·0 to 22·7 per 1000, further fell to 22·4 in the week ending the 2nd inst., but exceeded by 1·2 per 1000 the mean rate during the same period in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·4 in Leith and 15·2 in Aberdeen, to 27·5 in Glasgow and 30·8 in Paisley. The 546 deaths in the eight towns included 27 which resulted from whooping-cough, 14 from measles, 9 from diarrhœa, 7 from scarlet fever, 4 from "fever" (typhus, enteric, or simple), 3 from diphtheria, and not one from small-pox; in all, 64 deaths were referred to these principal zymotic diseases, against 76 and 81 in the preceding two weeks. These 64 deaths were equal to an annual rate of 2·6 per 1000, which corresponded with the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 17, 23, and 30 in the preceding three weeks, declined last week to 27, and included 15 in Glasgow, 3 in Edinburgh, 3 in Paisley, and 3 in Perth. The 14 deaths referred to measles showed a further decline from recent weekly numbers, and were all recorded in Glasgow. The fatal cases of scarlet fever, which had been 7 and 4 in the previous two weeks, rose again to 7 last week; 3 occurred in Edinburgh, 2 in Glasgow, and 2 in Paisley. The 4 deaths from "fever" were fewer than those recorded in any recent week, and included 2 in Edinburgh. Of the 3 fatal cases of diphtheria 2 were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 131 and 118 in the previous two weeks, were 124 last week, and exceeded by 8 the number returned in the corresponding week of last year. The causes of 78, or more than 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had risen in the preceding three weeks from 32·2 to 34·0 per 1000, declined to 33·5 in the week ending the 2nd inst. During the first four weeks of the current quarter the death-rate in the city averaged 33·4 per 1000, the rate during the same period not exceeding 21·9 in London and 18·8 in Edinburgh. The 227 deaths in Dublin last week were within 3 of the number in the preceding week, and included 40 which resulted from the principal zymotic diseases, against 29 and 28 in the previous two weeks; 17 were referred to measles, 9 to "fever" (typhus, enteric, or simple), 5 to scarlet fever, 5 to diarrhœa, 4 to whooping-cough, and not one either to small-pox or diphtheria. These 40 deaths were equal to an annual rate of 5·9 per 1000, the rate from the same diseases not exceeding 2·9 in London and 1·7 in Edinburgh. The deaths referred to measles, which had been 15 in each of the preceding two weeks, rose to 17 last week. The fatal cases of "fever" showed an increase of 5 upon the number in the previous week, and exceeded those recorded in any week since the end of January last. The deaths from scarlet fever, whooping-cough, and diarrhœa also exceeded those returned in recent weeks. Five inquest cases and 5 deaths from violence were registered, and 64 deaths occurred in public institutions. The deaths of infants showed a further increase, while those of elderly persons showed a slight further decline from those returned in recent weeks. The causes of 35, or more than 15 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

THE CUSTODY OF LUNATICS.

To the Editor of THE LANCET.

SIR,—In your annotation last week on this subject your advice to the medical officers of workhouses is "Let the authorities get out of the difficulty as best they may." Does this advice imply that the medical officers are not to deal with the lunatics placed under their charge? If so, such advice is impossible to be followed, as the medical officer seems to me to be obliged to give a certificate on the request of the master or relieving officer as to the state of a patient's mind and the advisability of letting a supposed lunatic go free. Should any damages be assessed to the medical officer from illegal detention on such a certificate, the parish will have to pay such damages, and such a custom has been followed in all the cases that have come to my knowledge. There is no reason, therefore, at present why workhouse medical officers should depart from their usual routine. I cannot admit the truth of the next sentence, where it stamps as a mischievous practice the sending of suspected lunatics to workhouses, or "that a workhouse is not the place for such cases," or "that a prison is better." Your solution "of the difficulty is to provide reception and probation wards in connexion with the public asylums for lunatics."

Now, as regards our large urban workhouses, most of which possess a staff of trained nurses, responsible male officers, resident medical officers, and suitable wards, why cannot wandering lunatics be attended there temporarily just as well as in asylums? They cannot be attended there permanently so well as at asylums, only because workhouses are in the crowded towns, and it is necessary for the welfare of the insane that they should live in the country. How the bridewells can be better than the workhouses I would like to know. In the bridewells there are neither nurses nor resident medical officers, nor suitable wards. The "prisons" have hospitals, but patients cannot be sent to prisons at midnight. If you provide suitable wards at all the bridewells, with resident medical officers and nurses, then the patients may be treated as well as in the lunatic wards of a workhouse; but I fail to see how they can be treated better. But this would be an unnecessary innovation, and, consequently, an unnecessary expense. It must be remembered that most of these suspected lunatics have to be dealt with in the night-time, and in the majority action must be taken at once—i.e., the patient must be taken into custody at once. You say these should be sent to probation wards in connexion with the large asylums. We will see how this would work in the parish of Liverpool. During last year 355 suspected lunatics were admitted into the lunatic wards of the Liverpool Workhouse. That is, according to your plan, that every twenty-four hours a magistrate would have to be looked for, and a journey of from ten to sixty miles or more made to Rainhill, Whittingham, Lancaster, or Prestwich Asylum, according as each place could or could not afford accommodation at the time. Under the present system, however, 152 only required to be removed to asylums, 203 recovering in a few days, and discharged to town, or taken charge of by friends, or sent into the workhouse as destitute. Many of these 203 went back to their work without any "insane" stigma upon them. They were looked upon as being "off it" for the time, through drink, grief, anxiety, or any of the other causes of temporary insanity that are rife in a large city. There is no stigma amongst the poor so hard to shake off as having once been in an asylum. No one will employ quondam lunatics; but if they have only been in the workhouse hospital a few days no such stigma attaches to them. It is true, that the workhouse stigma may be altogether eliminated by having a special hospital for such cases, but that would only be a change of name. Nor would it be necessary, as the great majority of these cases are destitute, and belong to the class cared for by guardians. The 152 are now pauper lunatics, 79 of the others were discharged to the workhouse. Some of the remaining 124 had friends who when communicated with by the parish authorities came forward and took charge of them, defraying expenses; but the majority of these, had they continued insane, would have become chargeable to the parish. Why, therefore, should another authority be constituted to deal with cases that from the nature of things will have eventually to be handed over to the present authority to support and look after?

It is only amongst those temporarily or permanently destitute that any trouble will arise. The better classes can procure assistance at any hour of the day or night to prevent their insane relatives from injuring themselves or others pending the preparation of the necessary forms and the arrival of a convenient time for allowing their removal to an asylum. But the poor cannot do this, and their insane relatives must be taken off their hands promptly. By the method practised in Liverpool this has been done for years, with the greatest possible advantage to all concerned. I sincerely trust the Local Government Board will legalise beyond all doubt such a system as has been used with us, as it will prove the most workable and most beneficent to the poor creatures concerned of any that has yet been proposed. It will provide for such cases when found half naked and dangerous in the streets, the bridewells, or in the homes of the poor. To take away this provision because relieving officers have in isolated instances removed respectable and harmless lunatics from comfortable homes is unnecessary, and very like yielding to panic on the part of the authorities. Any argument derived from some workhouses not having sufficient proper accommodation or attendance woule be met by insisting on suitable accommodation and attendance being provided in such places.

I am, Sir, yours truly,
WM. ALEXANDER, F.R.C.S.,
Visiting Surgeon, Liverpool Workhouse Hospital.
Liverpool, May 4th, 1885.

⁂ We do not suggest that medical officers should do less than their duty. All we desire to urge is that they should not do more. By all means sign certificates, but leave to the authorities the discovery of a way out of the difficulty which the absurd arrangements at present in force have created.—ED. L.

METROPOLITAN ASYLUMS BOARD.

To the Editor of THE LANCET.

SIR,—On Jan. 12th last I paid an independent and totally unexpected visit to the Darenth Small-pox Camps, and the general result of my inspection appeared in your journal on the 17th of that month. That the scale of diet, clothing, &c., was not illiberal was perhaps all too plain; indeed, the condition of the unfortunate inmates of that convalescent hospital was nearer akin to that of luxury than the opposite. The revelations now taking place with regard to the Homerton hospitals are still more striking, and prove, with the evidence of my own visit to that at Darenth, the absolute necessity of the speedy appointment of a thoroughly competent inspector or superintendent-general of all the institutions under the management of the Asylums Board. I therefore offer no apology for inviting the aid of your powerful pen in urging such a measure. At present each medical superintendent appears entirely free, and at liberty to tax the public purse to any extent his professional whims and fancies may suggest. What appears to me to be required is a firm and capable head, with full powers, but acting in concert with, and to some extent in subordination to, the responsible and able medical advisers of the Local Government Board, to organise a more or less uniform system with regard to the food, clothing, hospital comforts, and necessaries, and all the other details of the Asylums' *régime*. The idea, in all its fulness, will, I am sure, be at once clear and commendable to you, and therefore its further developmint appears to me quite unnecessary.

I am, Sir, yours truly,
JOHN INCE, M.D.,
H. M.'s Indian Medical Service (retired list).
Farningham, May 5th, 1885.

THE LATE DR. TIBBITS OF BRADFORD.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me, through your columns, to appeal for help for the widow and nine children of the late Dr. Tibbits, physician to the Bradford Infirmary.

A rapidly fatal attack of pneumonia put an end to his valuable life on April 14th, before he had had any opportunity to lay by money for his very large family of young children. All the property, inclusive of books and furniture, which he left behind, when realised and invested safely at 3½ per cent., is calculated not to produce more than £20 per year. His friends and medical brethren are raising a fund for the maintenance of his widow and children. If my letter should meet the eye of any of his old college friends who were contemporaries of his at University College, I think they may be induced to lend a helping hand. The case is truly necessitous and deserving. For ten years he laboured and maintained his large family without private income of any moment beyond that which he derived from physician's practice. The little capital he possessed on first starting consulting practice was trenched upon year by year to maintain his family, and just as this little store was approaching exhaustion, and just as success in practice was beginning to come, his life was suddenly brought to its close. Any contributions will be thankfully received by me or by Mr. Wm. Maw, the Secretary to the Bradford Infirmary.

I am, Sir, yours very truly,
J. APPLEYARD, F.R.C.S. & M.B. Lond.
1, Clifton Villas, Manningham, Bradford, Yorks, April 29th, 1885.

ROYAL COLLEGE OF PHYSICIANS.

To the Editor of THE LANCET.

SIR,—The number of Fellows elected last Thursday, though twenty for the double year, does not reach your proposed annual average of fourteen or fifteen; and as the selection for the last three or four years has been exclusively from Members within the decade 1870-80, at least thirty-seven out of thirty-eight being within this date, might not the complement be justly made up from senior Members, who otherwise will seem to be permanently excluded?

I am, Sir, yours truly,
A MEMBER (BY EXAM.) OF LONG-STANDING.
May 4th, 1885.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NORTHERN COUNTIES HOSPITAL FOR DISEASES OF THE CHEST.

THROUGH the resignation of Dr. John C. Murray a vacancy occurs in the honorary medical staff of this young but useful institution. The committee have made canvassing a disqualification, and I think the rule will have a good tendency, and might be well copied in like cases by some of our older medical institutions. Dr. John C. Murray is one of the founders of our Chest Hospital here, and has done good work in connexion with it. He is, I understand, about to release himself from the toils of town practice, and is removing to the south of Scotland. Dr. Murray a few years ago published a very successful work on the Use and Abuse of Tobacco.

THE MORTUARY QUESTION AT DURHAM.

Dr. Barron, at a late meeting of the Durham Sanitary Authority, in his farewell report as medical officer of health for the city, pointed out the urgent need which existed for a public mortuary being added to the sanitary conveniences of the city. A correspondent in the *Durham Chronicle* also refers to this want, which was painfully apparent in a case occurring a few days ago, and which became the subject of a coroner's inquiry, a remark from that official tending in the same direction. It appears that lately an old man who arrived from Newcastle by a day train was suddenly seized with an attack of illness which unfortunately proved fatal. It seems that the body remained in the ticket office for nearly three hours, and was exposed to the gaze of all passing in and out of the room during the time. No blame is cast on the railway officials by the writer; the painful occurrence was solely caused by the want of a public mortuary. The matter is to be brought before the committee of the Sanitary Authority with a view to its arrangement; but this is just one of those matters which are apt to be dropped under various excuses, unless prominently kept before the authority.

EPIDEMIC OF MEASLES AT JARROW.

A very serious and extensive outbreak of measles is reported at Jarrow, causing considerable mortality; indeed, there seems to be a wave of this disease passing slowly over our northern towns. At Jarrow, the Town Council, at a meeting presided over by the Mayor, decided to close at once all the week-day and Sunday schools in the borough.

CARLISLE MICROSCOPICAL SOCIETY.

At the meeting of the above Society an able and exhaustive paper on "Micro-organisms" was read by Dr. Lediard of Carlisle. An animated discussion followed the paper, and the lecturer received a cordial vote of thanks from a large meeting.

MUNIFICENT BEQUESTS TO THE TYNESIDE CHARITIES.

The late Mr. Frederick Glenton, many years a merchant in Newcastle, left a considerable amount of money to be distributed in charity, the chief scope of his charitable bequests being in the direction of institutions that had mainly for their object the befriending of children. The following local medical charities may be mentioned as having been benefited, among others, by cheques from the surviving executor, Mr. Wm. Nesham of this city—viz., Hospital for Sick Children, £500; Eye Infirmary, £500; Deaf and Dumb Institution, £400; Lying-in Hospital, £100.

The information which I gave you in a former letter respecting the regulations of the University of Durham appeared previously in one of our local and usually well-informed papers.

Newcastle-on-Tyne, May 4th.

EDINBURGH.

(*From our own Correspondent.*)

OPENING OF THE SUMMER SESSION.

The summer session in the University and Schools of Medicine commenced on Monday, May 4th. Notwithstanding the awkward arrrangement by which lecturers were obliged to commence their teaching on a day when many students are almost necessarily absent—an arrangement for which the University authorities are responsible,—the classes are reported as more than usually crowded. In the Extra-Academical School are several new courses of lectures, amongst which there are a short series of lectures on "Mental Disease," by Dr. J. Batty Tuke; and a class of Operative Surgery, under the direction of Mr. C. W. Cathcart; whilst within the University, in addition to the ordinary work of the session, a series of special courses is announced in the Faculty of Arts, conducted by the assistants to the professors in the various subjects.

PROFESSOR RUTHERFORD AND THE ANTI-VIVISECTIONISTS.

For some years the anti-vivisectionists have made great capital by depicting the Edinburgh Professor of the Institutes of Medicine in most sanguineous hues as the repulsive figure-head of a craft which is searching for the pole of some Tartarean sphere of scientific fallacy. His laboratory has been publicly likened to a slaughterhouse, and himself—even more explicitly than by mere inference—to the presiding genius of such a place. From time to time in past years the Professor has repelled these attacks—at times, in fact, in such strong terms as to increase the thrill of horror by which the adverse camp is constantly possessed. These reprisals are, however, things of the past; and of late the Professor has supplied an excellent example of the patient bearing of the cross. This might have continued indefinitely had not a recent attack of more than ordinary bitterness, supported by sweeping misstatements and championed by three clergymen, roused the long-suffering Professor to an energetic vindication of his own position in the matter. In a lengthy letter addressed to the local papers Professor Rutherford details the causes, nature, and results of his experiments on the liver, concluded some eight years ago, which have received wide recognition as of great scientific value, and which have since proved a never-failing source of bitterness to his opponents. What his present defence lacks in "wingéd" words, it more than makes up for in the calmness of its statements and the clearness of its reasoning; and, although public discussion of professional topics is apt in general to do more harm than good, as it usually lowers professional dignity, it is still to be hoped that, in the present instance, the public mind may be stimulated to reject the nauseous bolus of narrowness and fallacy which has of late been so vigorously thrust upon it.

CHARITIES AND THE POOR LAW.

Last week a public conference on the above subject was held in Edinburgh, at which several important papers were read by gentlemen whose position gave them the authority of specialists. Amongst other topics, the prevailing custom of employing paupers as nurses in union infirmaries was discussed, and all but unanimously condemned.

Edinburgh, May 5th.

PARIS.

(*From our Paris Correspondent.*)

PROFESSOR VULPIAN AND THE RECENT EXPERIMENTS ON THE SEVERED HEADS OF CRIMINALS.

The question has again been mooted as to whether those who have been decapitated suffer; and after additional experiments on the head of Gamahut, who was guillotined on the 24th ult. for the murder of a widow lady in Paris, coupled with those related by Claude Bernard, the presumption is that they do, for under the influence of transfused blood the blanched features recovered almost their normal expression, the eyelids were slightly open, and the lips quivered for a few seconds, as if to express some perception communicated from the brain. The conclusion, then, is that, so long as the brain contains any blood, the head of the decapitated person, which falls into a receptacle prepared for the purpose, is capable of seeing, of hearing, and of knowing that it is separated from the body. This view, however, was repudiated by Professor Vulpian at the last meeting of the Academy of Medicine on the following grounds:—A strong blow applied to the head, or a less severe one to the stomach, would cause instantaneous syncope; that is to say, consciousness would for the moment be entirely abolished. So it would be in the case of the severed head, but of course without any possibility of recovery; the weight of the guillotine falling upon the neck would produce the same result. Moreover, syncope would be occasioned by the sudden division of the carotid arteries, and the consequent emptying of the arterial system of the brain. Therefore, at the very moment that the brain ceases to receive the vivifying fluid from the heart, it loses all power of excito-motility, as well as all power of sensation; all this transpires as quickly as thought, and its duration may be compared to a flash of lightning. It happened opportunely that a dog that was undergoing some experiments in Professor Vulpian's laboratory was suddenly seized with hæmorrhage. Advantage was taken of this circumstance to immediately expose the brain and submit the latter to faradisation. Scarcely half a minute had elapsed between the arrest of the circulation and the galvanic irritation. It was impossible to obtain any movements in the legs. The effects of the electricity produced in the muscles of the head and nose were not, according to Professor Vulpian, due to the physiological transmission effected by the brain, but to the neighbourhood of the source of irritation; the brain, having lost all power of excito-motility, would in this case act as a mere sponge; and if such a condition was found to exist for only half a minute after the arrest of the circulation, the interpretation put on the effects said to be produced on severed heads by other experimenters must certainly be considered erroneous.

THE MICROBES OF CHOLERA DEJECTIONS.

Dr. Bochefontaine is persevering in his efforts to prove the innocuousness of the microbes cultivated in the diarrhœa of cholera patients, whether they be introduced into the system by the stomach or by hypodermic injection. He *cultivated the microbes of the diarrhœal liquid in peptonised* gelatine, with which he performed a series of experiments. At four different times he swallowed a quantity of this gelatine, containing bacilli of the second and third cultures, without feeling in the least any abnormal phenomena. In the next place, he injected hypodermically into guinea-pigs, and then into himself, a mixture composed of equal parts of water and of cultivated gelatine. These different experiments would, according to the author, show that the ingestion of the cultures of cholera microbes may not produce any morbid symptom in man; they prove that the hypodermic *injection of these cultures in man and in* animals may, if they are injected in comparatively large doses, produce inflammatory phenomena of a more or less grave character. If, on the contrary, the proportion of the microbic culture is weak, the injection produces no effect whatever. If we compare the results of these experiments, in which were employed microbic cultures, with those that were furnished by ingestion by the stomach and by the hypodermic injections of diarrhœal liquid, which formed the subject of a previous communication made by Dr. Bochefontaine (see my letter in THE LANCET of Nov. 22nd last), we are led to believe that the physiological *troubles* produced by this liquid are due to the action of a special *substance, and not to the* development of the microbic germs which it contains. These experiments further show that the blood of man and of animals in a normal state possesses the property of destroying *the microbes of* the diarrhœal liquid of cholera patients cultivated in peptonised gelatine.

The Executive Committee of the Shirley Murphy Testimonial Fund have, since Mr. Murphy's return to England, had the opportunity of ascertaining his wishes with regard to the movement which had been inaugurated during his absence, and in deference to his desire, they do not intend to proceed further with the presentation of a testimonial. The course which will be adopted in the disposal of the fund must necessarily be in the hands of the subscribers, who, we understand, will be immediately consulted. The Committee, however, propose to forward to Mr. Murphy an address as previously stated.

THE SERVICES.

THE RUMOURED EMPLOYMENT ON ACTIVE SERVICE OF CIVIL SURGEONS.

We are authorised to state that the rumour to which we referred in our last issue as to arrangements having been made for the employment on active service of civil surgeons at £3 per day is incorrect. No such posts are being made, or are in contemplation on the terms stated.

INDIA OFFICE.—The Queen has approved of the transfer to the half-pay list of Surgeon George Augustus Cones, of the Bengal Medical Establishment.

ADMIRALTY.—Staff Surgeon Michael Upington Greany, M.D., has been placed on the retired list of his rank.

The following appointments have been made:—Staff Surgeon Robert Grant, to the *Pembroke;* Staff Surgeon Robert W. Biddulph, to the *Orontes;* Staff Surgeon Richard V. M'Carthy, to the *Rupert;* Staff Surgeon Cecil Drake, to the *Duncan;* Staff Surgeon George Curtis, to the *Devastation;* Staff Surgeon Nicholas T. Connolly, to the *Ajax;* Staff Surgeon Mark A. Harte, to the *Hotspur;* Staff Surgeon William B. Fletcher, to the *Repulse;* Surgeon Frederick J. Lilly, to the *Devastation;* Surgeon George F. Dean, to the *Hotspur;* Surgeon George Welch, to the *Ajax.*

YEOMANRY CAVALRY.—Suffolk: Surgeon Robert Macnab, M.D., resigns his commission.

ARTILLERY VOLUNTEERS.—1st Worcester: Surgeon Geo. Wyndham Crowe, M.D., resigns his commission; Acting Surgeon Robert William Edginton, M.D., to be Surgeon.

RIFLE VOLUNTEERS.—2nd Cheshire (Earl of Chester's): Henry William King, Gent., M.D., *to be Acting Surgeon.*—10th Lanarkshire (Glasgow Highland): Donald Campbell Black, Gent., M.D., to be Acting Surgeon.—1st Volunteer Battalion, the Worcestershire Regiment: Arthur Robert Waddell, Gent., M.D., to be Acting Surgeon.

MEDICAL NOTES IN PARLIAMENT.

Cremation.

IN the House of Lords, *on the 5th inst., the Earl of* Dalhousie, in reply to the Earl of Onslow, stated that the Government did not consider it any part of their duty to encourage or to discourage the practice of cremation. The Government possessed no power at present to act in the matter.

Medical Act (1885) Amendment Bill.

In the House of Commons, on the 30th ult., Dr. Lyons moved the second reading of the Medical Act (1858) Amendment Bill. On the motion of Mr. T. P. O'Connor the debate was adjourned.

Burgh Police and Health (Scotland) Bill.

On the 1st inst. the following were named to act on the Select Committee on this Bill:—The Earl of Mar and Kellie, the Earl of Minto, Lord Balfour of Burleigh, the Duke of Argyll, the Marquis *of Lothian, the Earl of* Dalhousie, and the Marquis of Tweeddale.

Small-pox at West Ham.

Mr. G. Russell, in reply to Mr. Hopwood, said that there had been a severe epidemic of small-pox in the West Ham sub-district, and the returns for the last three years showed that the number of children unaccounted for, as regards vaccination, had been *greater than in other districts* in the neighbourhood of the metropolis. There had been insufficient hospital accommodation in the district; but, apart from that, he was not aware that defects *in sanitary* precautions had been the cause of the disease and mortality.

The Volunteer Medical Staff Corps.

On the 4th inst. the Marquis of Hartington, replying to Sir S. Northcote, said that an application had been received by the War Office from the officers of the Edinburgh University Volunteer Medical Staff Corps, asking that the corps might be included in the new Volunteer Medical Staff Corps. The Volunteer Medical Staff Corps was in some sense an experiment, and although it was *hoped to* extend the scheme, it was not considered desirable that there should be more than *one corps* at present.

Vaccination.

Mr. G. W. Russell, in reply to Mr. Hopwood, stated *that* at the Sheffield Hospital in 1882 the medical officer and a ward-servant who had both been revaccinated had attacks of small-pox so mild that scarcely any rash appeared. The cook, *who* had not been revaccinated, but who had previously had small-pox, had an attack in a *modified* form. The only severe case in the hospital at the time was that of a patient who had *never been* vaccinated; this patient died. A nurse who had not been revaccinated had an attack of a qualified nature, and the only severe case was that in which the patient had not been vaccinated and died. In reply to an inquiry by Mr. Hopwood as to whether he had communicated to the authors of the "Facts concerning Vaccination," published with the sanction of the Local Government Board, his view of the unguarded nature of the statement that no hospital nurse had been attacked with small-pox after revaccination, Mr. Russell replied that the National Health Society had been informed of the reply which was given on the subject on the 31st of March last.

Sewage Works at Tottenham.

On the 5th inst., Mr. Russell stated, in answer to a question by Mr. J. Stuart, that the Local Government Board have sanctioned a loan of £13,000 for works in connexion with the sewage outfall of the Tottenham district, with a view to the purification of the sewage before it is discharged into the Lea.

Small-pox Hospitals.

In the House of Commons on Thursday, Mr. Russell, in reply to Sir Lyon Playfair, who asked whether in the case of officers and servants for the service of the Metropolitan Asylums Board hospitals a proper interval was always allowed to elapse between their revaccination and their entering on their duties, and whether it was the fact that certain officers or servants at the Fulham Small-pox Hospital had entered on their duties without revaccination, said that inquiry had been made, and it was found that in the case of the North-Western, South-Eastern, and South-Western Hospitals an interval is allowed to elapse between the revaccination of the officers and servants and their entering on their duties. In the first-mentioned hospital the interval is stated to be forty-eight or seventy-two hours. As regards the Eastern Hospital, it has been the custom to revaccinate the officers and servants on the day of arrival at the hospital or the day following. At the hospital ships no interval elapses between the revaccination and exposure to small-pox infection. At the Western or Fulham Hospital the officers and servants are usually revaccinated on the day of their entering on their duties. There have, however, since May, 1884, been two instances in which the revaccination was not performed until some days after the assistants had commenced discharging their duties, and this was in consequence of an omission to report the cases to the medical superintendent.

The Health of the Troops on the Nile.

Lord Hartington, in answer to questions by Viscount Lewisham and Colonel Dawnay, said he telegraphed to Sir Redvers Buller an inquiry with reference to statements which had appeared in the *Standard*, and received a reply that the hutting was not finished at Debbeh, Merawi, and Kurot, but would be this week. The troops had had day shelter for more than three weeks. The percentage of sick was 7·1 per 100; the health of the troops was not very good, but it was not materially worse than at the time of the last report, on April 15th.

Obituary.

EDWARD T. TIBBITS, M.D. LOND.

AT Bradford, Yorkshire, on April 14th, at the age of forty-five years, Dr. Tibbits fell a victim to acute pneumonia. Worn out by an anxious attendance upon his eldest daughter, through an attack of the same disease, he became an easy prey himself. After ten years of anxiety—which those alone can appreciate who have struggled and waited for the slow growth of consulting practice,—the subject of our notice was called away just as the sky looked brighter, and as the fruits of patient labour appeared almost to be within his reach. In him the town of Bradford, and especially the medical charities, have sustained a grievous loss, which it will be difficult to make good.

Dr. Tibbits was educated at Repton School, and at University College, London. As a student, he held the posts of physician's assistant to Sir William Jenner and ophthalmic assistant to Mr. Wharton Jones at University College Hospital, clinical assistant at the Brompton Consumption Hospital, and house-surgeon to the Coventry and Warwickshire Infirmary. He gained the exhibition and gold medal in Chemistry in 1860 at the 1st M.B. Examination of the University of London, and passed his M.D. in 1869. Ten years ago he relinquished general practice at Rugeley in Staffordshire, chiefly on account of health, and was elected physician to the Bradford Infirmary, and a little later to the Fever Hospital and to the Institution for the Blind. These institutions he served faithfully to the time of his fatal illness. In 1879 and 1880 he was president of the Bradford Medico-Chirurgical Society, and always took a lively interest in its proceedings.

Naturally unpretentious and modest, yet somewhat impulsive and obstinate in nature, and possessing at all times the courage of his opinions, it was no easy matter to turn him aside, or to prevent him from carrying out any measure which he believed to be right. Cultured and refined as he was, he gathered round him a large circle of friends, who deeply regret their loss.

He was twice married, and has left behind him a widow and nine children, who, from no fault of his, are almost absolutely without provision for the future.

During his later years Dr. Tibbits held very decided views on the germ theory of disease, and on the bacillar hypothesis of woolsorters' disease in particular. He was a frequent contributor to the pages of THE LANCET, and notably a paper on the "Modern Theory of the Action of Digitalis" (THE LANCET, 1881). In religion he was a staunch Churchman and in politics a Liberal Conservative. Dr. Tibbits was buried at Clayton Church on April 17th, when large numbers of his fellow-townsmen attended to pay tribute to his memory.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on the 30th ult.:—

Ball, James Barry, M.D. Lond., Belgrave-road.
Batten, Rayner Winterbotham, M.D. Lond., Gloucester.
Davies, Arthur Temple, M.B. Camb., Finsbury-square.
Gamgee, Arthur, M.D. Edin., Manchester.
Griffiths, Herbert Tyrrell, M.D. Camb., Brook-street.
Martin, Sydney Harris Cox, M.D. Lond., Gower-street.
Phillips, John, M.B. Camb., Harley-street.
Rockwood, William Gabriel, M.D. Madras, Colombo, Ceylon.
Stewart, Edward, M.D. Brussels, Harley-street.

On the same day the following were admitted Licentiates:—

Anderson, James, M.D. Toronto, Portland-road, Dublin.
Armstrong, Hugh, Chalcot-crescent.
Barber, Halford Vaughan, Sandmere-road.
Barendt, Frank Hugh, Hampstead-road, Elm-park, Liverpool.
Basset, Walter, Knowle-road, Bristol.
Berkley, Ernest James Gibson, Camberwell-road.
Bird, Henry, Vicarage Villas, Neasdon.
Blight, John Henry, Chobham-road.
Booth, William Henry, Plymouth.
Bown, John Quinton, St. Mary's Hospital,
Browne, Harold Elliott, University-street.
Caley, Guthrie Neville, Clarence Villas, Windsor.
Childe, Charles Plumley, Bexhill, Hastings.
Clarke, Fincastle George Barlow, Fordwych-road.
Clift, Samuel Leonard, Tressillian-crescent.
Coleman, William Edward, Albert-street.
Cooper, Charles Bolingbroke, Gambier-terrace, Liverpool.
Creasy, Rolf, Guy's Hospital.
Emmett, Richard, St. George's Hospital.
Fowler, Charles Owen, London Fever Hospital.
Freeland, Ernest Harding, Middlesex Hospital.
Gentles, Thomas Lawrie, Derby.
Green, Charles Robert Mortimer, Rotherhithe New-road.
Growse, William, Bethlem Hospital.
Harcourt, Vincent Ximenes, Duncan-terrace.
Howard, Herbert, Trinity-square.
Hugill, George Frederick, Rosedale, Chislehurst.
Jackson, Herbert Francis, Talbot-road.
Jackson, Percy Vaughan, Portsdown-road.
Jessop, Edward, St. Bartholomew's Hospital.
Kershaw, James Edward, Brompton-square.
Kidd, Hugh Cameron, Leamington-road Villas.
Lamb, Hugh, St. Thomas's Terrace.
Lee, William John, Harcourt-road, Brockley.
Lipscomb, Edgar Richard Senhouse, Southwark-park-road.
Lysaght, William Conner, Frederick-place, Clifton, Bristol.
Mathew, Charles Pynsent, Milman-street.
Mathews, Frank Edward, Lansdowne-terrace, Richmond, Surrey.
Maynard, Frederick Pinsent, Barnes.
Meeson, Alfred, High-park-street, Liverpool.
Morris, Herbert Mackinlay, Henrietta-street, Covent-garden.
Norris, Edwin John, Barndale-road.
Nutting, Philip Henry, Lady Margaret-road.
Page, Harry Marmaduke, Westbourne-park.
Phillips, Lawrence W. Kinglake, Hove Dispensary, Brighton.
Pietersen, James, Lambeth-palace-road.
Pinhorn, Richard, Warwick-gardens.
Plowman, Sidney, St. Thomas's Hospital.
Rhys, Watkin Llewellyn, Crofton-road.
Roberts, Henry, Colebrook-row.
Smith, Frederick John, Bishopsgate Without.
Southern, Francis Gerald, Ludlow.

Soutter, James, Hull.
Steer, Adam William Thorburn, St. Bartholomew's Hospital.
Tanner, Herbert, St. Mary's Hospital.
Underwood, John Charles, Ashford.
Walsh, Charles Lawrence, St. Bartholomew's Hospital.
Whishaw, Reginald Robert, Cornwall-street.
Williams, John Frederick, Infirmary, Westmoreland-road.
Willis, Arthur Keith, West End-lane.
Willoughby, Alfred Harvey, Aberdeen-place.
Wunderlich, Otto Frederick, St. Luke's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 30th ult.:—

Ackland, Charles Kingsley, L.S.A., Bideford, Devon.
Curgenven, John Sadler, L.S.A., Craven-hill-gardens.
Fooks, Henry, L.S.A., Kennington.
Gould, Ernest Edward, L.S.A., Exeter.
Lewis, Jenkyn, L.S.A., Llanon, Cardiganshire.
Richards, George William, M.B. Durh., Stourbridge.
Ritchie, Edward Duguid, L.S.A., Wimbledon-park.
Stedman, Frederick Osmund, L.S.A., Leatherhead.
Willan, Leonard James, L.S.A., Stoke Newington.

Admitted on the 1st inst.:—

Clift, Samuel Leonard, L.R.C.P.L., St. Johns.
Farmer, William Henry Francis, Anerley.
Gruchy, Charles William de, L.R.C.P.L., Ludlow.
Hehir, Patrick, L.R.C.P. Ed., Calcutta.
Howard, Herbert, L.R.C.P.L., New Beckenham.
Lee, William John, L.R.C.P.L., Devonport.
Martin, Joseph Henry Walklate, L.S.A., St. Albans.
Pietersen, James, L.R.C.P.L., Lambeth-palace-road.
Pinhorn, Richard, L.R.C.P.L., Warwick-gardens.
Roberts, George Augustus Edward, L.S.A., Twyford.
Smith, John Turville, L.S.A., Manchester.
Steer, Adam Wm. Thorburn, L.S.A., Jamaica.
Sutton, Alfred, L.S.A., Brockley.
Tronson, William Francis, L.S.A., Oxford-gardens.

Admitted on the 4th inst.:—

Bown, John Quinton, L.R.C.P.L., Nottingham.
Chick-Lucas, James Robb Goodman, Portsea.
Elkington, Henry Percival George, Gillingham-street.
Ellis, Donald Mackay, Chudleigh.
Fegen, Charles Milton, Bedford.
Godfrey, Henry William, M.B. Aberd., Hornchurch.
Harthan, Herbert Damville, Sandbach, Cheshire.
Henderson, George Christopher, Natal.
Lever, Frederick, Epsom.
Lewis, Charles James, Liverpool.
Moore, Walter Francis, Preston.
Parsons, Henry Compton, Hampton Wick.
Pearson, Albert Edward Alexander, Horsforth, near Leeds.
Postlethwaite, Frank, Oxford-road.
Pott, Francis Henry, Cornwall-gardens.
Wethered, Frank Joseph, L.S.A., Clifton.
Woods, Frank, Warrington.

Admitted on the 5th inst.:—

Apthorp, East, Hornsey.
Austin, Herbert Ward, Devonport.
Beard, Frederic, Trinity-square.
Calrow, Thomas, Bury, Lancs.
Eales, George Young, Yealmpton, Devon.
Jabboor, Habeeb, Beyrout.
Jervis, Arthur, Connaught-square.
Podmore, Robert, Eastbourne.
Pratt, George Arthur, Wolverhampton.
Price, Alfred Edward, Clapham.
Pritchard, Joseph James Gauler, Blackheath.
Ramsay, Herbert Murray, Redhill.
Scott, George Henry, Osset, Yorks.
Tuke, Thomas Seymour, Albemarle-street.
Whishaw, Reginald Robert, Liscard, Cheshire.

Admitted on the 6th inst.:—

Bent, George, Gladstone-street.
Bindloss, Edmund Frederick, Leighton-road.
Calvert, James, Grenville-street.
Clark, John Stallard Foot, Saltash, Cornwall.
Dill, Robert Charles Gordon, Burgess-hill.
Dornford, Charles Thomason, L.R.C.P. Ed., Wantage.
Green, Albert, Forest-hill.
Halley, Percy Oswald Ward, Newport Pagnell.
Helps, George Crawford, Weston, near Bath.
Knaggs, Francis Henry, Putney.
Richmond, William Stephenson, Stanwick-road.
Scatliff, Phillip Melancthon, Macaulay-road.
Smith, George Francis, St. Anne's-terrace.
Wylde, Harry Frank, Manchester.

UNIVERSITY OF OXFORD.—At a congregation held on the 1st inst. the degree of M.D. was conferred on

Lloyd, Francis, Jesus.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 1st inst. Dr. P. H. Pye-Smith was appointed an elector to the Professorship of Physiology, and Professor Robertson Smith was appointed an elector to the Professorship of Sanskrit. The degree of M.D. was conferred on

Lane, James Oswald, St. John's.
Lyon, Thomas Glover, Emmanuel.

UNIVERSITY OF GLASGOW.—The following gentlemen passed the Third Professional Examination for the degrees of M.B. and C.M. in April last:—

Adam, Basil J.
Aird, Alex. W.
Alexander, W. M., M.A., B.Sc.
Beattie, Robert M'G.
Brown, James A.
Brown, Walter F.
Campbell, Arch. T.
Carmichael, Alex.
Crawfurd, Robert K. B.
Cullen, John B. F.
Currie, John.
Davidson, James F.
Davis, George W.
Dewar, Daniel M'K.
Duff, Jas. K., M.A.
Fergus, Wm. Henry.
Gardner, R. Irvin.
Goff, Bruce E.
Haddow, R. W. T.
Hamilton, Robert.
Hay, Walter.
Henry, Robert.
Hickin, Herbert.
Manners, Wm. H.
Marshall, John.
Marshall, William.
Mathieson, Alex. L.
Miller, Alfred E.
Monteagle, Henry W. B.
MacColl, Donald S.
M'Conechy, James.
M'Houl, Hugh M.
MacKechnie, C. A.
MacKeith, Alex. A.
MacKeith, John.
M'Lachlan, James.
MacLeod, David T.
Macquarrie, John A.
Pyle, William.
Ramsay, Robert.
Ritchie, John.
Robertson, Robert.
Robertson, William.
Rowat, John.
Roxburgh, Alex.
Sinclair, H. W.
Stewart, John (Renfrew).
Steil, James W. H.
Thorburn, John.
Wallace, Wm. (Glasgow).
Wallace, Wm. (Greenock).
Watson, James.
Wyllie, James.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 30th ult.:—

Curgenwell, John Sadler, St. Bartholomew's Hospital.
Gaudevia, Merwanjee Nowrojee, Bombay.
Graham, Charles Nicol, Guy's Hospital.
Pinhorn, Richard, St. George's Hospital.
Roberts, Arthur, London Hospital.
Smith, John Turville, Manchester School of Medicine.
Sutton, Alfred, Guy's Hospital.

At the Preliminary Examination in Arts held at the Hall on April 30th and May 1st and 2nd, the following candidates were successful:—

FIRST DIVISION.

*Lindsay, Herbert Stott.
*Stradling, Henry R. Skynner.

SECOND DIVISION.

Aylward, Walter Charles.
Biddle, Henry George.
Blakeman, Charles Smith.
Bromley, Francis Edward.
*Burditt, Ralph Austin.
Cory, Ernest Richard.
Dryland, Leslie Winter.
Elgee, William.
Farncombe, Wm. Turberville.
Goddard, Bertram.
Harrison, Chas. Alan.
*Jones, Frederick Warner.
Kirby, William Owen.
*Livesey, Edgar Wm.
Marder, Nicholas.
Mole, Alfred Ernest.
Montagu, William.
McTaggart, Norman E. E.
*Osborne, Oswald.
Parish, Beauchamp Frederick.
Pearce, Charles Ross.
Richards, J. Barrow Osborn.
Steele, Geo. Herbert.
Templeton, Percy.
Wade, Albert Holland.
Yonge, Eugene.

* Passed also in Elementary Mechanics.

Passed in Elementary Mechanics alone:—

Andrew, Francis William.
Gane, E. Palmer Steward.
Greene, Arnold James.
Linstead, Edward Flatman.
St. Cedd, R. G. Whitworth.
Smith, Alfred.
Spilsbury, Frank Hands.
Webb, Frank.

Passed in Greek alone:—

Fraser, Frank.
Fraser, Elias.

Passed in German alone:—

Newington, John S.

Passed in Chemistry alone:—

Andrew, Francis William.

THE Prince of Wales has contributed one hundred guineas to the Dublin Hospital Sunday Fund.

THE annual conversazione of the Royal Society was held on the 6th inst.

WESTMINSTER HOSPITAL.—The Frederick Bird Prize and Medal for 1885 have been awarded to Mr. Alfred S. Gubb.

THE PHARMACEUTICAL SOCIETY.—The annual dinner of this Society will be held at the Holborn Restaurant on the 19th inst., at 6.30 P.M.

ROYAL INSTITUTION.—Professor Odling will give the first of two lectures on "Organic Septics and Antiseptics" on Saturday, May 16th.

THE Committee of the Leeds Harehills Cycling Club, being strongly of opinion that members intending to compete in the road competitions arranged for by the Club should be physically fit, recommend that all intending competitors furnish medical certificates to the secretary at the time of entering.

Superannuation.—Mr. E. N. Sison, late medical officer of the eleventh district of the Holborn Union, has been granted a superannuation allowance of £70 a year.

The *Cronica Medica* of Lima, Peru, states that during the month of January there were thirty-seven deaths in that city from small-pox, thirty-two of the victims being under twelve years of age.

The festival dinner in aid of the funds of the North London or University College Hospital will be held at the Langham Hotel on the 13th inst., His Royal Highness the Prince of Wales in the chair.

Presentation.—Dr. Raitt, who delivered a series of "First Aid to the Injured" lectures for ladies at Manchester, has been presented by the members of the class with a marble timepiece and an address.

The Aberdeen Club.—The next half-yearly dinner of the Aberdeen University Club, London, will be held at the Venetian Salon, Holborn Restaurant, on Saturday, May 16th, at 7.45 p.m., the Earl of Aberdeen in the chair.

On the 2nd inst. the body of Dr. Phelps of Exeter was found wedged between two rocks at Ness, Teignmouth. It is supposed that while walking home from a picnic he was seized with heart disease and fell into the water.

The festival dinner in connexion with the Royal Hospital for Children and Women, Waterloo-bridge-road, will be held at Willis's Rooms on the 13th inst., His Royal Highness the Duke of Cambridge, K.G., in the chair.

At the annual meeting of the Metropolitan and National Nursing Association for providing trained nurses for the sick poor, on the 1st inst., it was stated that during the past year 527 cases had been nursed, and 17,374 visits paid.

At the 14th anniversary of the Brighton Young Men's Christian Association, Professor Drummond from Glasgow attended, and delivered two addresses in the banqueting-room of the Royal Pavilion. A deputation of medical students and others from Edinburgh University have also been holding special services, which have proved highly successful.

Measles in Chester.—The alarming outbreak of measles in Chester continues to spread, and two of the largest schools in the city have just been closed. The disease has broken out in Mrs. Gladstone's Home for Children at Hawarden, and at least one of the inmates has been removed to the Chester Infirmary. Sixteen deaths have already been registered since the epidemic set in.

The German Hospital.—The fortieth anniversary dinner in aid of the funds of this institution was held on the 6th inst., when it was stated that a total of 24,500 patients had been treated during the past year. Of the 1822 in-patients admitted during the year, 353 were accident cases, most of them being English. During the evening subscriptions, and donations amounting to £3473 were announced by the secretary.

The Devonshire Hospital and Buxton Bath Charity.—The annual general meeting of the supporters of this institution was held on the 2nd inst., when an exhaustive account of the great and increasing usefulness of the charity was read by Dr. Robertson. During the past year 2491 in-patients were admitted, exceeding the number received during 1883 by 261. The average number of patients daily resident in the hospital was 157·1.

Anthropological Institute.—At a meeting of this Society on the 28th ult. the following papers were read:—By Mr. A. L. Lewis, on the Past and Present Conditions of certain Rude Stone Monuments in Westmoreland; by Admiral F. S. Tremlett, on Quadilateral Constructions near Carnac, in which was described certain enclosures explored by the late Mr. James Miln; and by M. Jean L'Heureux, on the Kekip-Sesoators, or ancient sacrificial stone of the north-west tribes of Canada.

Important Circular to the Police.—Consequent upon the numerous representations which have been made with reference to the treatment of persons arrested for alleged offences, and especially to prevent a recurrence of the mistakes which have been made when prisoners suffering from illness have been treated as drunken persons, the Secretary of State has issued a circular to the police authorities throughout the kingdom, directing that strict orders should be given to the police that when any prisoner complains of illness, shows symptoms of illness or of being in a feeble state of health, whether he make complaint or not, the police-surgeon should be summoned and the prisoner medically examined. If the prisoner is found to be suffering from serious illness, a report as to his health is to be presented to the magistrates before whom he is brought.

On the 23rd ult. an inquest was held on the body of George Webb, M.D., who was found dead at his residence, 101, Hollydale-road, Peckham. Dr. Webb was well known in the district, and a few days before his death had himself attended as a witness at a coroner's inquest. Death was certified to be due to fatty degeneration of the heart.

Sanitation in Holborn.—On the 23rd ult., an inquiry was held by Mr. Cubitt-Nicholls, from the Home Office, as to an official representation made by the Holborn District Board of Works, with a view to obtain an order directing the Metropolitan Board of Works to deal with an unhealthy area adjoining Brook's Market, as a metropolitan improvement. Evidence was given as to the shocking sanitary condition of the locality, it being stated that the population was 232, and that during two years there had been 154 cases of sickness—scrofulous cases, sore throats, or cases of consumption not being included in this number. The court rose after a sitting of seven hours.

Telephone and Telegraph Wires.—On the 27th ult. Sir Joseph Bazalgette was examined before the Select Committee of the House of Commons, who are inquiring into the law controlling the overhead and underground wires. Sir Joseph stated that the system of overhead wires was first commenced twenty years ago. At that time there were no underground wires. There were now 800 miles of overhead wires in the metropolis, and ten times that quantity of underground wires. He would give the power of making bye-laws to the Metropolitan Board of Works, the district authorities merely acting as the executive, without any appeal to a Government department. Under the Building Act, which divided London into seventy-two districts, with a surveyor to each, they had all the machinery necessary for dealing with this question.

University of London.—At the meeting of the Senate of the University of London held last week the following gentlemen were elected examiners for 1885-86:—Chemistry: Professor J. Emerson Reynolds, M.D., F.R.S.; Professor T. E. Thorpe, Ph.D., F.R.S. Botany and Vegetable Physiology: Professor Bayley Balfour, M.D., D.Sc., F.R.S.; Professor F. O. Bower, B.A. Comparative Anatomy and Zoology: Professor E. Ray Lankester, M.A., F.R.S.; Professor Alex. Macalister, M.D., M.A., F.R.S. Practice of Medicine: W. H. Broadbent, M.D.; W. Miller Ord, M.D. Surgery: W. M. Baker, Esq.; Sir William Mac Cormac, M.Ch., M.A. Anatomy: Professor D. J. Cunningham, M.D., C.M., F.R.S.E.; H. Greenway Howse, M.S., M.B. Physiology: Professor Arthur Gamgee, M.D., F.R.S.; Professor Gerald F. Yeo, M.D. Obstetric Medicine: F. H. Champneys, M.A., M.B.; John Williams, M.D. Materia Medica and Pharmaceutical Chemistry: J. Mitchell Bruce, M.D., M.A.; T. Lauder Brunton, M.D., D.Sc., F.R.S. Forensic Medicine: Augustus J. Pepper, M.S., M.B.; Professor George Vivian Poore, M.D., B.S.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning at the latest.*

Bailey, C. F., M.B.Lond., M.R.C.S., has been appointed House Physician to the West London Hospital.

Barnard, Arthur J., M.R.C.S., L.R.C.P.Ed., Junior House-Surgeon to the Darlington Infirmary, has been appointed Junior House-Surgeon to the Royal Albert Edward Infirmary, Wigan, Lancashire, vice John Buchanan, M.B. and C.M.

Benham, Henry James, M.D.Lond., M.R.C.S., has been appointed Physician to the East Suffolk and Ipswich Hospital.

Buchanan, John, M.B. and C.M.Glas., Junior House-Surgeon to the Royal Albert Edward Infirmary, Wigan, Lancashire, has been appointed Senior House-Surgeon at the same, vice John Henry Jackson, M.B. and C.M.Ed., resigned.

Flinn, John James, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Everton No. 1 District of the West Derby Union, vice Worrall, resigned.

Godfrey, Frank, L.R.C.P., L.R.C.S.Ed., has been appointed Honorary Consulting Surgeon to the Islington Dispensary.

HARPER, ALEXANDER, M.B.Dur., M.R.C.S., has been appointed House-Surgeon to the West London Hospital, vice Maitland Thompson, L.R.C.P.Ed., L.M., M.R.C.S., resigned.

HOLLIS, ELPHINSTONE, M.D., C.M.Ed., has been appointed Physician to the East Suffolk and Ipswich Hospital.

MARSHALL, WILLIAM, M.R.C.S., L.S.A.Lond., has been appointed Junior House-Surgeon to the Huddersfield Infirmary.

POPE, PERCY, M.R.C.S.Eng., L.R.C.P.Ed., has been appointed Poor Law Medical Officer, Public Vaccinator, &c., for the Hayling (North and South) District of the Havant Union.

SHAW, WILLIAM, M.R.C.S., has been appointed Medical Officer of Health for the Shire of Barrabool, Australia.

SHILLITOE, RICHARD, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District of the Hitchin Union, vice R. R. Shillitoe.

SIMMONS, HAROLD, L.R.C.S., L.S.A.Lond., has been appointed Physician Assistant to the Middlesex Hospital.

VERRALL, THOS. JENNER, L.R.C.P.L., M.R.C.S., has been appointed Assistant-Surgeon to the Sussex County Hospital.

WARNER, FREDERICK A., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the West London Hospital, vice James Herbert Menzies, M.R.C.S., L.S.A.Lond., resigned.

WATSON, ARCHIBALD, M.D.Paris, M.R.C.S., L.S.A.Lond., has been appointed Professor of Anatomy at the New School of Medicine, Adelaide University.

WOOD, PERCY MOORE, L.R.C.P.Lond., M.R.C.S.E., J.P.S.A., has been appointed Government Medical Officer and Protector of Aborigines for the Port Darwin Northern Territory, South Australia.

Births, Marriages, and Deaths.

BIRTHS.

BARRACLOUGH.—On the 21st ult., at Dulwich-road, Herne-hill, S.E., the wife of R. W. Sutton Barraclough, M.D., of a son.

BOTHAMLEY.—On the 26th ult. at Bromley, Kent, the wife of R. Broughton Bothamley, M.R.C.S., of a son (stillborn).

BRIDGMAN.—On the 1st inst., at Croasdale Bank, Slaidburn, Yorkshire, the wife of Mr. Herbert A. Bridgman, L.F.P.S.G. and L.M., of a daughter.

COLLIER.—On the 2nd inst., at Capstone House, Hammersmith, the wife of N. C. Collier, L.R.C.P., of a daughter.

PRINGLE.—On the 29th ult., at Angelton, Bridgend, the wife of H. T. Pringle, M.D., Medical Superintendent of the Glamorgan County Asylum, of a daughter.

TOWNSEND.—On the 27th ult., at Benares, the wife of Surgeon-Major Townsend, A.M.S., of a daughter.

MARRIAGES.

BURGESS—KEW.—On the 29th ult., at the Parish Church, Clapham, W. Milner Burgess, M.R.C.S., &c., of Harlesden, to Ellen Isabella, daughter of F. E. Kew, Esq., of Clapham.

CATON—IVORY.—On the 5th inst., at Christ Church, Edinburgh, Richard Caton, M.D., of Liverpool, to Annie, only daughter of the late William Ivory, W.S., of Edinburgh.

FARAKER—CREGEEN.—On the 28th ult., at Christ Church, Forest-hill, J. J. Faraker, M.R.C.S., L.S.A.Lond., to Ada J. Cregeen, third daughter of the late J. J. Cregeen, M.D., F.R.C.P.E., and step-daughter of W. Cregeen Faraker, M.R.C.S.E., L.S.A.Lond., Ravensdale, Forest-hill.

GARLICK—PETERKIN.—On the 30th ult., at St. Mary's Parish Church, Clitheroe, George Garlick, M.D.Lond., to Annie Gertrude, second daughter of William Peterkin, Craven Bank, Clitheroe.

STORRS—CROKER.—On the 30th ult., at St. Mary's, Penzance, Arthur Storrs, M.D., M.R.C.P.E., of Mexborough, Yorkshire, to Ellen Walters, youngest daughter of the late John Gifford Croker, M.D., F.G.S., of Bovey Tracey, Devon.

UNDERHILL—MURIEL.—On the 28th ult., at St. Giles' Church, Norwich, by the Rev. W. C. Muriel, Rector of Debden, Essex, assisted by the Rev. [illegible] W. N. Ripley, Vicar of the Parish, Frede[illegible] Tipton, Staffordshire, son of W. Lee [illegible] of Tipton, to Beatrice Alice, second daughter of Charles Evans Muriel, Esq., of Norwich.

DEATHS.

BARBER.—Lost at sea, in February, in the Royal Mail steamer *Humber*, Alfred Barber, M.R.C.S., youngest son of Alfred Barber, of Eastrop House, Basingstoke, aged 28.

BUCHANAN.—On the 2nd inst., William Buchanan, M.D., of Church Gate, Cheshunt, Past Master of the Society of Apothecaries, in his 85th year.

CHAPMAN.—On the 3rd inst., at The Laurels, Chiswick, John Strange Chapman, M.D., Deputy Inspector-General of Army Hospitals, in his [illegible]th year.

DITCHETT.—On the 28th ult., at Louth, Lincolnshire, William Edwin Ditchett, M.R.C.S., aged 49.

HIGGINS.—On the 6th ult., at Heathfield, Peel, Isle of Man, Henry Higgins, M.R.C.S., L.R.C.P., &c., aged 57.

HOWARD.—On the 25th ult., at Sandgate, Kent, John William Howard, M.R.C.S., L.A.C., L.M., in his 58th year.

HOYLAND.—On the 1st inst., at his residence, York-road, Hove, Brighton, Edward Hoyland, M.R.C.S., &c., formerly of Sheffield, aged 74.

MACLEAN.—On the 28th ult., at Portman-street, Portman-square, John Maclean, M.D., aged 68.

PHELPS.—On the 1st inst., at Teignmouth, suddenly, by an accident, F. P. Phelps, surgeon, of Victoria-terrace, Exeter, aged 52.

WHITE.—At Broad-street, Pendleton, J. Atkin White, M.R.C.S., L.S.A.Lond., aged 42.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

Monday, May 11.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

Tuesday, May 12.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. The Right Hon. the Earl of Northesk: Exhibition of a Collection of Worked Jade from New Zealand.—Mr. J. H. Kerry-Nicholls: The Origin and Characteristics of the Maoris in the King Country, New Zealand.

Wednesday, May 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. E. Wethered: Structure and Formation of Coal.—Mr. A. W. Waters: Use of the Avicularian Appendage in the Classification of the Bryozoa.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens as usual. Dr. Benington: Tetanus in the Puerperium.—Mr. Lawson Tait: Double Uterus, &c.—Dr. Biglow: Gynæcological Surgery.

Thursday, May 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Tyndall: Natural Forces and Energies.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Living Specimens. 8.30 P.M. Mr. W. A. Brailey: On the Condition of the Ciliary Nerves in certain Diseases of the Eye.—Mr. E. Nettleship: Note on the Spontaneous Disappearance of Diabetic Cataract.—Mr. J. B. Lawford: Case of Nævus of Choroid (with Microscopic Specimens).—Mr. Jonathan Hutchinson: On Reflex Ophthalmitis.—Mr. W. Spencer Watson: Intra-ocular Gumma in a Child the subject of Inherited Syphilis.—Mr. Simeon Snell: Case of Periodic Paralysis of Third Nerve.—Mr. W. H. Jessop: (1) Choroiditis Disseminata; (2) Rupture of Eyeball (living specimens).

Friday, May 15.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Dr. W. N. Thursfield: On the Etiology of Goitre.—Mr. F. E. Atkinson: On an Outbreak of Diarrhœa traced to Polluted Water.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. A. Hughes Bennett and Mr. R. J. Godlee: Case of Cerebral Tumour.

ROYAL INSTITUTION.—9 P.M. Prof. Burdon Sanderson: Cholera.

Saturday, May 16.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Odling: Organic Septics and Antiseptics.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

"TOLERANCE AND ADVANTAGE OF LARGE DOSES OF POTASSIUM IODIDE."

To the Editor of The Lancet.

Sir,—In The Lancet of April 18th, under the above heading, you quote from the *New York Medical Record* a case in which the dose of iodide was increased from eight to thirty grains three times a day. I think every one who has had much to do with syphilis must have met with cases in which larger doses were not only tolerated, but were necessary in order to obtain the desired effect. My own rule, when iodide is indicated and well borne, has long been to increase the dose more or less rapidly according to circumstances, until some effect is produced, quite irrespective of quantity. The largest daily dose I remember to have prescribed was 540 grains (iodide of ammonium); but I have no doubt more has been, or might be, required. He who holds his hand under the impression that he has given the iodides a full and sufficient trial because a certain number of grains or drachms has been reached, will fail to obtain some of the most important results which it is in the power of iodine to produce.—I am, Sir, yours faithfully,

Stafford-street, W., May 2nd, 1885. Arthur Cooper.

To the Editor of The Lancet.

Sir,—In your issue of April 18th a case of tolerance of large doses of potassium iodide is recorded. In 1873 I had to treat a case of chronic ulcerated throat, supposed to be of syphilitic origin. The patient had been under treatment for some time without benefit from ten-grain doses of potassium iodide, when I increased the doses to twenty grains, and ultimately to forty grains, three times a day, with marked improvement. He took two-drachm doses for several weeks, until the throat had healed. On account of a slight relapse, he had to resume his old doses for a short time, afterwards reducing the amount to thirty grains twice a day. The patient took the latter quantity for several months. I prescribed it with aromatic spirit of ammonia, and he took each dose with half a pint of milk. What may be thought the most remarkable feature of the case is that he gained more than a stone in weight during the exhibition of the remedy—and the milk.

In contrast with the above, I have prescribed two-grain doses of potassium iodide for a stout, free-living patient on several occasions; but he always detects it, no matter what pains I take to disguise the fact of its administration. In this case it causes a nasty metallic taste.

I am, Sir, yours obediently,

Somerby, Oakham, April 27th, 1885. J. Jackson.

Late Assistant.—We think decidedly that there is a moral obstacle to practising. Our correspondent undertook to sign a bond not to do so. That he was not asked to sign does not lessen the obligation not to practise.

Lex.—Authorities differ. There is no proof of it.

Surgeon-Major Sargent's paper will be inserted in an early number.

"IMPRISONING AN UNDOUBTED LUNATIC."

To the Editor of The Lancet.

Sir,—I was pleased to see that you drew attention, in your issue of April 25th, to the case of poor Freund being imprisoned for bawling in St. Paul's Churchyard. It is quite true he is a lunatic. I have known him for some ten or fifteen years. Whilst at his studies at St. Thomas's Hospital no student was more persevering or had greater prospects; but, I believe, family misfortune deprived him of the means of following the profession. For a time he went as an assistant to medical men, but was so strange and irregular in his habits that he was advised to give it up. Since then his life has been more or less a blank, and it would be a real charity to assist him into the home of some medical man who would look after him; or he should go to Bethlem or some place where he will have proper treatment. I should be willing in any way to assist in his support. I am, Sir, your obedient servant,

Sackville-street, W., May 1st, 1885. James Startin.

M.R.C.S. or M.R.C.V.S.?

Medical titles are always rather puzzling to the public. It is, however amusing to see in a provincial paper a letter from a local resident denying a report that his child had been suffering from small-pox, and adding a "doctor's certificate" to that effect, the doctor's signature giving as his qualification "M.R.C V.S." On looking at the Medical Register, we find he is "M.R.C.S." Did the patient's father insert the *V* to improve appearances?

Insurance.—Mr. Cook's essay and the supplement relating to industrial insurance are published by the author, Arthur I. Cook, at Finsbury-square-buildings, London, E.C.

Dr. H. S.—We regret that we cannot assist our correspondent in the matter.

"RINGWORM."

To the Editor of The Lancet.

Sir,—Will you allow me to make a few remarks on Dr. Murphy's letter under the above heading in your last issue.

1. There is but little doubt that, as a rule, ringworm of the body will not recur (provided there is no disease of the scalp and no reinfection) if some treatment be continued until the skin is all but normal again at the circumference of the patch, and the margin is quite free from all papules and desquamation, and the place is not raised above the level of the surrounding skin.

2. I think Dr. Murphy is right when he remarks, "The germ that revived probably found a safe hiding-place in some of the hair-follicles." The only way to be certain that every trace of the disease has been eradicated where downy hairs exist is to carefully scrutinise the place with a lens, and to see that there are no minute hairs affected. I have often noticed a few of the small hairs broken off and diseased on a patch of body ringworm which might otherwise have been considered cured.

3. In examining epidermic scales for the fungus in ringworm of the body, it is far better to look for the mycelium threads than the conidia. The mycelium is to be seen as long, slender, pale-greyish, sharply contoured threads like ribands, jointed at irregular intervals, and forming a network between the epidermic scales. To obtain these scales for examination, the inner part of the outer ring, just where it is beginning to desquamate, should be scraped.

4. Of course, I may be mistaken, yet I think it is very possible if the patch seen by Dr. Murphy on March 12th, when it appeared to be well, had been closely looked at with a lens, that one or two broken-off downy hairs would have been detected. If a child be sent back to school at the end of a fortnight, it is always advisable to examine the place from time to time in case of any recurrence.

I am, Sir, yours faithfully,

Christ's Hospital, May 4th, 1885. Alder Smith.

J. F. W.—There is no district in England which is specially beneficial in this affection. Sea-air is usually to be avoided, as it acts as a local irritant; but the whole question of climate is one to be determined by a full consideration of all the elements of the particular case.

DRINKING PARAFFIN OIL.

To the Editor of The Lancet.

Sir,—As drinking paraffin oil by accident or design is not uncommon, the following case may be of interest.

M. B——, aged eighteen, primipara, went through a normal labour on the 5th inst., in which she was attended by an externe from Guy's Hospital. On the twelfth day she showed symptoms of puerperal mania; but no medical assistance was applied for. On the fourteenth day, whilst left alone, she attempted suicide. I found the patient in an excited condition, with an incised wound two inches in length on the left side of the neck. Whilst suturing this wound, I detected the odour of paraffin oil, and she did not deny that she had swallowed some. I also found the mark of a ligature round her neck, consisting of a wheal with reddened edges for the greater part of its circumference, and an abrasion for the remainder. The pupils were moderately dilated, pulse 90, full. The patient was given warm milk-and-water, followed by twenty grains of copper sulphate in warm water. In about fifteen minutes she vomited freely, and not less than fifteen ounces of oil floated on the top of the vomit. This was proved to be paraffin, and corresponded with the amount missing from a bottle which had been left on the table. It must have remained in the stomach for at least forty-five minutes. She experienced no further inconvenience as the result of the triple attempt, but her mental condition being dangerous, she was removed to an asylum on the sixteenth day. I am, Sir, yours truly,

Great Charlotte-street, April 22nd. Henry Willson.

Doubtful.—1. Yes.—2. The infection precedes the disease by a few days, and lasts till the disease is at an end.

Dr. Hudson (Leeds).—The paper is marked for early insertion.

INSTRUMENT FOR IRRIGATING THE UTERUS.

To the Editor of The Lancet.

Sir,—In your report of the meeting of the Midland Medical Society in your last issue you state: "Dr. Neale showed an instrument for irrigating the uterus," &c. "The makers are Messrs. Woodall, York." This should be "Messrs. Wood and Co., York."

I am, Sir, yours obediently,

York, May 4th, 1885. Thos. J. Russell.

CHOLERA AND ITS PREVENTION.

To the Editor of THE LANCET.

SIR,—I did myself the honour to send you, on Oct. 18th, 1884, a pamphlet which I published in 1871, called "Hindu View of Cholera: a Lecture."

I venture to draw your attention to the late reports from Valencia, in Spain. They are there adopting the method which my lecture suggests. At page 1 I say: "The philosophy, or 'form,' of the great discovery of Jenner, and of the practice of inoculation, has *never yet been* grasped or sufficiently studied. Had it been, it is probable that now we might have known a potential preventive against cholera." At page 9: "*In Europe you now happily seek* more a prophylaxis than a cure; but your efforts are cramped and misdirected by the poison and germ theories. The 'pregnant' instances of vaccination, inoculation, quinine, iodine, mineral waters, changed climate, &c., as prophylactics have not yet had a shadow of their just weight on your method." Of course, the instances here cited are in some cases used by way of analogy, to illustrate my method. Again, at page 11: "The splendid light which the instances of vaccination, quinine, &c., give, not having their just effect on your method, it thus happens that whilst cholera appears in the race of man you are content to practise a pernicious treatment of symptoms, and to put trust in disinfectants, directed against totally inefficient causes." At page 13: "When we remember the great power of quinine and arsenic in a *series of fevers*; when we know that a series of fevers of ten to twenty years' duration can be speedily removed by small amounts of these substances; when we remember the instances of prophylaxis which *nature herself* presents, such as change of climate, passions for food, and certain elements, &c.—we cannot but be full of confidence for future discovery. We must grasp what Bacon has taught us on the 'pre-eminency of instances.'" "Many directions are open to *the student for discovery* which may lead to results as *great as that of* Jenner." At page 16: "On the other hand, I daily expect to hear the announcement that some student has, by following the analogies and alliances of nature *(and which are open to, and part of, all of us), been* led to perceive the 'form' of cholera, and to perceive the direction or element of supply, which, given to the system, would *render the first change or paralysis*, whose residual necessities are the symptoms we call cholera, impossible." "......and that every disease *must* have its prophylaxis."

My lecture is an argument from the *a priori* Hindu philosophy, which philosophy has been re-drawn in Europe by Descartes, Kant, &c., but which has yet too little penetrated your Western method. I argued in my lecture that cholera is not "specific"; that it is an allied "gradation"; that it had long culminating pre-cholera stages in molecular changes in the system, and that *our hope of dealing* with it was by coordinating the system prior *to* the appearance of that stage which is commonly known as cholera. But I must not take up your space—except on the ground that *my* quotations of 1871 may be suggestive *for* further prophylactic trials. My own trials, were I again in charge of cholera districts, would be to give quinine, acids, and *some* of the aromatic class as prophylactics.—I am, Sir, yours truly,

London, April 28th, 1885. GOLAUB SING, M.D.

A. B.—The answer will *entirely depend upon the* terms of the appointment. The locality in which a medical officer of health resides is a point which is considered when his appointment receives the sanction of the Local Government Board; but they do not of necessity require residence within the district. Indeed, in some instances access to the various portions of a district is facilitated by residence at a railway centre outside the district. Hence there is no rule on the subject.

A Patient is thanked for his communication; but we do not think his suggestions would enlighten the profession.

"AUTUMNAL STONE."

To the Editor of THE LANCET.

SIR,—With reference to Mr. Robert Jones' inquiry about these Chinese preparations, I may *refer him to page 224 of* my "Chinese Materia Medica" (Trübner). The "Ts'iushih" is the product formed by the evaporation of the urine of young children, mixed with common *salt or sulphate of lime to hasten* the crystallisation. It consists mainly of urea mixed with lithates, phosphates, &c. It is met with in small cakes, crystalline, deliquescent, and evidently moulded *in little cups*. It is salt to the taste, and is used as a diuretic in renal disease. It is often kept in Chinese kitchens to soften fresh meat required *for* immediate use. "Wu hu No" means "sal ammoniac from Wu-hu hien in Nganhwin province," where these "autumnal stones" are made. Made *from* ammoniacal urine, the Chinese confound these "stones" with sal ammoniac (nau-sha), a drug in great repute as a solvent *for opacities* of the cornea. Chinese oculists are remarkably successful in removing nebula and albugo of the cornea by applications of this "autumnal stone," mixed with sulphate of soda.—I am, Sir, yours faithfully,

FREDK. PORTER SMITH,
Member of the Asiatic Society of Paris.
Shepton Mallet, May 2nd, 1885.

[illegible].—Our correspondent is really the best judge in the question he puts to us. The case was a very important *one*, and his charges should be at once dignified and reasonable.' We would make only one suggestion—viz., to let the charges have reference to visits, time, and distance, and not to medicines.

[illegible].—There seems to be no great harm in the announcement.

INSANITY IN BENGAL.

IN 1883 the number of admissions into the lunatic asylums in Bengal, which had fallen in 1882 to 185, the lowest number on record, rose to 209. The increase was the most marked in the case of males, of whom 184 were admitted, against 144 in the previous year; while the number of females admitted was 25, against 21 in 1882. The number of readmissions was 23, and consisted of males only. The daily average population of the asylums was 873·67, against 857·12 in the previous year. Out of the 232 cases admitted and readmitted during the year, causes were assigned in 131 instances—29 being moral causes, and 103 physical causes. Of these latter 76 were ascribed to Indian hemp, and of this number only 34 recovered. These figures, however, give no idea of the total number of lunatics in Bengal, and asylum statistics do not afford a true indication of the prevalence of insanity, since only the most dangerous cases are admitted into asylums in India.

Mr. F. C. Batchelor.—We do not see our way to assist our correspondent in the matter.

"CASCARA SAGRADA."

To the Editor of THE LANCET.

SIR,—In reply to Mr. T. L. K. Davies's question in your last issue, I beg to say that cascara sagrada possesses both hepatic and intestinal principles; and at present there is no definite therapeutical study of the action of either principle in an uncombined form. The chemical composition of the drug consists of three resins, about 10 per cent. of the weight of the bark, tannin, oxalic, malic, fat oil, wax, starch in abundant *quantity, and a small percentage of a volatile oil* bearing the characteristic odour of the bark. Its most reliable preparation is the fluid extract. It acts upon the hepatic secretions and circulations, the whole gastro-intestinal canal, stimulating its morbid condition, and the neighbouring glands to healthy action. As a cholagogue it is invaluable. In chronic constipation its action is good, producing full, easy, pleasant stools, without any tormina, tenesmus, or nausea. The liquid extract, combined with the tincture of iodine painted on the hypogastric region, *daily*, until the bowels are moved easily, has given *the same result* after repeated trials on patients suffering from habitual constipation. As a remedy for dyspepsia it is superior to many others of its class, being *pleasant to take*, and *producing* no nausea.

I am, Sir, yours obediently,
Geneva, May 4th, 1885. H. C. GLANVILLE.

Mr. David J. Allen.—No comment on the case is to be found in either of the numbers mentioned.

"DISINFECTING CHAMBERS."

To the Editor of THE LANCET.

SIR,—I see, in looking over some back numbers of THE LANCET, that in the issue for April 18th "Medical Officer of Health" inquires as to the best disinfecting chamber. I would strongly advise your correspondent to employ Lyon's Steam Disinfector, which by super-heated steam quickly produces a heat of 230° F. It has been used in these camps for the last year, giving complete satisfaction, and working for close on 8000 patients. The agent, Mr. John W. Lyon, 1, Cowper's-court, Cornhill, will doubtless give all information.

I am, Sir, yours faithfully,
C. W. WAYLEN,
Medical *Superintendent, Darenth Camps* for
May 5th, 1885. Convalescing Small-pox Patients.

⁎ We have received other letters bearing testimony *to* the value of Lyon's Disinfector.—ED. L.

"THE TITLE OF 'DOCTOR.'"

To the Editor of THE LANCET.

SIR,—I have *often* been *tempted to reply in* your notes anent the above title, but until I saw the letter signed "M.D." in your issue of the 25th ult. I refrained.

"*M.D.*" says he thinks that if the Colleges of Physicians and Surgeons allow their Licentiates to take the title of "Doctor" they should repay him for the time and money—and, I may add, the 2000 or 3000 hours *of* extra study (often after bedtime)—spent. "M.D." adds that if they do not do so, he must consider that he has been mercilessly robbed. Who can say he is not in the right? I think your correspondent's letter more to the point than most letters upon this vexed subject.

I am, Sir, yours obediently,
Stranraer, April 27th, 1885. J. CARRICK MURRAY.

S.—We should be unable to find room for the replies which would probably be called forth by the insertion of our correspondent's note.

"CONTAGIOUS DISEASE CARDS."

To the Editor of THE LANCET.

SIR,—What Dr. Kenyon says in his letter published in your columns last week is correct, and your observations thereon are but natural. *The* figures, as stated, are those already published by Mr. Francis Vacher, to whom I am deeply indebted for the kind permission given to me for employing them in the cards in question. Henceforth means shall be taken to make his claim to their authorship known.

I am, Sir, your obedient servant,
Maidstone, May 2nd, 1885. MATTHEW A. ADAMS.

Unqualified.—The only thing that can be done is to ascertain the exact facts. If they *prove* that a qualified medical man has abetted the practice of the lady in question or other unqualified persons, they should be laid before the Medical Council; but evidence short of proof is of no use.

M.B.Edin.—Our correspondent should mention the facts to his friend. The case seems a special one, and our correspondent seems to us entitled to the fees. But between right-minded friends there should be no difficulty.

RE NON-COMBATANTS.

To the Editor of THE LANCET.

SIR,—I am now attending an officer who, with his regiment, was present when, on March 22nd, the Arab forces of Osman Digna rushed on the zereba held by the 1st Battalion of the Berkshire Regiment and penetrated one corner, as the local newspapers put it. This officer tells me—"The first wounded I saw were two men of the Army Hospital Corps, who are sent into battle unarmed, for a good walking-stick would be better than their side-arms, and who were completely at the mercy of the enemy with their long spears and shields." This is carrying the doctrine of non-combatant to a length which borders on the dangerous, and suggests the question as to how far the authorities are liable for sending men into battle unprotected because they choose to call them non-combatants. I am, Sir, yours obediently,

May 8th, 1885. PAX.

Mr. C. C. Burman (Belford, Northumberland).—The joint should first be smeared with oil; then a mould taken with a paste of plaster-of-Paris, from which it is easy to get a cast with a second fluid of the paste.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 1st, 1884, appears the following notice of an appointment—viz., that of "Hozier, C. H. Smith, to the Gundagai Hospital." As I am, and have been, the only qualified medical officer attached to the above institution for the past fifteen months, you will greatly oblige by giving the above the most unqualified contradiction. I am, Sir, yours obediently,

Gundagai, New South Wales, March 9th, 1885. J. J. O'DWYER.

Clinical Lecture

ON A CASE OF

DISSEMINATED CEREBRO-SPINAL SCLEROSIS IN AN EARLY STAGE, AFFECTING EXCLUSIVELY THE RIGHT EXTREMITIES.

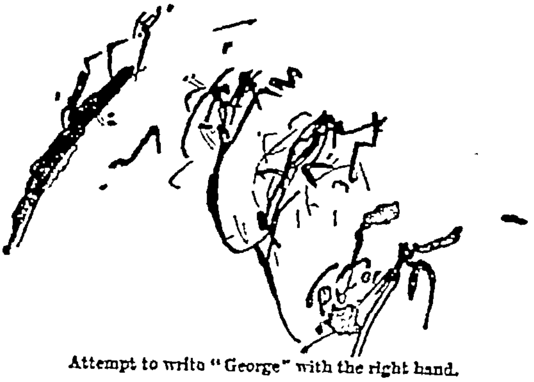
By DYCE DUCKWORTH, M.D., F.R.C.P.,
PHYSICIAN TO, AND LECTURER ON CLINICAL MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—I bring before you to-day a patient lately mitted to Bed 1 in John ward, whose case furnishes me with some points of great interest, to which I shall ask your attention. It is one of a class well fitted for a clinical lecture, which, as you know, is nothing if not demonstrative, and little more than a systematic or didactic one if the patient is not brought before you. Clinical medicine has all to do with individual cases, and that teaching of it is most proper which best illustrates the points to be noted to each of you in as direct and living a manner as possible.

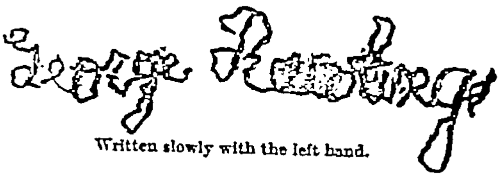
I will presently tell this man to walk across the theatre, and ask you to notice his gait. If you look at him first as he stands at rest, you will not observe anything remarkable about him. You see a young man in seeming good health, well nourished, and with complete control over his equilibrium. I now ask him to close his eyes. He stands erect, and without any tremor or instability. And now, as he walks, you notice a peculiarity in the action of his right leg. This limb moves stiffly, and there is over-action of it. It is lifted higher off the ground than the other, and is clumsy in movement. We say there is some spastic action in it. I now give him this glass of water to take in his right hand. At once, you see, a violent *spasmodic* action occurs, vigorous tremulation, so great that he nearly empties all the water before he has well seized the glass. If he next attempts to raise the vessel to his lips the movements become more and more exaggerated, so that all the water is spilt and the empty glass rattles against his teeth. I remove the vessel from his hand, and all the spasm ceases forthwith. *As he stands* quietly once more, you notice that the right arm remains tranquil and free from tremor. I try his power of grasp in each hand, and find a marked weakness in the right one, although he is a right-handed man. I now lay bare his forearms and compare the condition of his muscles. You observe no signs of wasting; the muscles are well developed and of good and equal tone on both sides. On examining his face, you see that his muscles of expression are stable and free from tremor, his lips firm, and his eyeballs quite steady. His pupils are unequal, certainly, but that is due to the action of atropine in one of them, used to allow examination of the retina of the right eye. No squint; no facial palsy. Testing his sensory functions, we find no abnormal state; all is as it should be. On inquiry as to any subjective sensorial sensations, he assures us all is natural in each of the four extremities. To curtail our further examination, I may add that there is nothing more to be detected by any physical methods we can employ, save that the knee-reflexes are exaggerated, markedly on the right side, while no ankle-clonus can be elicited. We have, then, a seemingly healthy and vigorous young man, whose only troubles are a clumsy limping gait, due to disorderly action of his right leg, and inability to employ his right hand and arm because of powerful tremulation and disorderly spasm, which come on the instant he directs his will into this extremity; and this is all. Before he leaves the theatre I ask him to repeat a sentence after me. You notice that he *speaks* clearly and fluently—with a good Wiltshire accent to be sure, but without any hesitation or difficulty; and yet, again, on protruding his tongue, you find no noteworthy tremor or peculiarity in it. Let us now take up the history of this case; it is very brief.

G. R——, aged twenty-one, a groom, was sent up to us by a former pupil of the hospital, and admitted on Feb. 14th. He states that *nine months* ago trembling movements began in his right arm, which prevented him from following his occupation. Later on the right leg became affected, so that he could not walk far on account of the weakness in it. *Inquiry into his past history* revealed no important illness. He had never had rheumatism, and there was no known history of this or of gout in his family. He had never had chorea, although his present ailment was at first believed to be of this nature. There was no neurotic history in his family, no indication of any previous paralytic attack or hemiplegia, no injury of any kind, and no history of fits. His duties entailed exposure to all kinds of weather, but to no extraordinary exposure. Previous to admission, he had been treated, we learned, with arsenic, belladonna, mineral water bathing at Bath, &c., all without avail.

You have already noted that the patient appears a healthy and well-nourished man, and that so long as he makes no voluntary efforts with the limbs of the right side of his body there is no indication of disease about him. I show you a specimen of his attempt to write his name. (See woodcut.) After violent efforts to control the right hand he made this unintelligible series of scrawls. With the left hand he has learned to write fairly legibly, but slowly and with difficulty, still without any *spasm or tremor*. He is awkward in setting his right forefinger on any point; thus he makes bad shots at his nose when he tries to touch the end of it, and hardly succeeds in getting near it. Dr. Steavenson has given us a report on the electrical reactions of the muscles of the affected limbs, and he states that they all react normally to both continuous and interrupted currents, and that there is no loss of electro-sensibility. We have seen the exaggerated reflexes at the knees, especially on the affected side; and you may note an increase in the supinator-reflex of the right arm. No fibrillary muscular contractions. On examining the thorax, nothing abnormal is found. The heart-sounds are healthy and sufficiently loud. The urine is natural and the sphincters act perfectly. Special senses not perverted. No vertigo. Knows where his feet and hands are. Retinæ perfectly healthy, and optic discs well-defined. No nystagmus; pupils react naturally; no strabismus. No history of syphilis, and no signs of either inherited or acquired disease of this character. No tenderness on percussing the cranium at any point. In trying to follow with his right toes a circle drawn on the floor is very clumsy and erratic. He can jump, though with exertion of more force than is necessary for the distance traversed. The difficulty with the right leg is best seen when he tries to run.



Attempt to write "George" with the right hand.



Written slowly with the left hand.

We find, on the whole, more negative than positive signs *in this man*, and yet we have very definite symptoms before us. What is the lesion here, and where is it? What is the diagnosis and what the prognosis, and the best treatment of it? I mentioned that chorea had been at first suspected in the case. *Chorea is sometimes* one-sided, and often so, for a time in many instances. You would not or you should not long be mistaken as to this. You know that choreic movements *are incessant* except during sleep, and not only elicited by effort, although they are aggravated by voluntary efforts. And you would not expect to meet with a case of one-sided chorea lasting continuously for nine months. We may, therefore, put that aside. You think, perhaps, of another nervous disorder characterised by tremors and paralysis agitans; the shaking palsy (Parkinson's disease) suggests itself to you. Is this the malady before us? Here is Parkinson's own definition, written in 1817; observe if it tallies with our case: "Involuntary tremulous motion with lessened muscular power in parts not in action, and even when supported; with a propensity to bend the trunk forwards and to pass from a walking to a running pace, the senses and intellect being uninjured." This definition will not apply here. The rule is for the tremor to be persistent and constant in shaking palsy, and rather to cease or moderate when action is induced. The contrary is the case here. Action at once induces tremor. The age of this patient is against his being the subject of shaking palsy, this disorder being very rare before forty years of age are reached. Have we here to deal with a case of so-called post-hemiplegic chorea? I think not, because we have no history and no signs of a past attack of hemiplegia, and the characters of this man's tremors are not those of the disorder I have alluded to. To mention mercurial tremors is sufficient. These are symmetrical, and affect the head, and the signs of mercurialism are always obvious. We can also exclude hysterical tremors and malingering.

We are brought, at last, to consider this case, then, as one of a class known as insular or disseminated cerebro-spinal sclerosis, or Charcot's disease, as it has been called. It is a remarkable example, certainly, because the disorder is, at present,—note, I say, *at present,—hemiplegic in character, and also manifestly in an early stage.* We do not often see such cases. This is our diagnosis: sclerotic patches situated in the left half of the brain, possibly in corpus striatum or crus, and possibly in some portion of the medulla spinalis. I should not like to pronounce with greater certainty anything more than this at present, though I might exclude the inferior frontal convolution and parts around the fissure of Sylvius, with some other regions. We may exclude scrofulous and syphilitic disease in the case, and we are in face of the characteristic lesions which are usually found in these cases, and for which I refer you to your studies in morbid histology. The age of our patient is just that at which this malady declares itself. It is equally common in each sex, and very rare after forty. Exposure to cold has been a commonly assigned cause. In this disease no muscular *wasting* occurs, although loss of muscular *power* is found, and no electrical changes arise. Paresis precedes the tremors, and the reverse is the case in shaking palsy. The reflexes are exaggerated. I should not omit to point out to you that many symptoms are wanting in this patient to complete the picture of a typical case. Such a one we had fifteen months ago in John ward. For example, one looks for nystagmus, and for certain symptoms referable to disorder in the medulla oblongata in most of these cases. I never met before with the exact conditions you see in this man; but, still, I have hardly any hesitation in making my diagnosis.

As to prognosis. This is certainly grave. I surmise that we have so far only early symptoms before us, and that the disease will make sad progress in time. We may fear the onset of paresis and tremors in the sound limbs, and the implication of speech with what are termed bulbar symptoms. The sclerotic process may spread and new patches of it occur in other portions of the cerebro-spinal system, thus setting up new symptoms. The course of the malady is slow, and may occupy from five to ten years. Deceptive periods of improvement may occur from time to time. Too often the disease goes on from bad to worse till the patient is rendered helpless and bedridden, the limbs becoming rigid and paralytic dementia supervening. Can we do nothing to arrest this terrible process? Must it go on to the bitter end? Alas! the resources of our art are, we must honestly avow, powerless as yet to avert the progress of this terrible malady. Physicians have been very assiduous in elaborating the differential diagnosis of nervous diseases of late years, but in respect to therapeutics we have as yet scored few triumphs. The outlook is bad, and we might almost despair of rendering help. We shall never do this, I hope, but rather strive the harder to find means of arresting this untoward process. No one drug is pre-eminently indicated. I am giving this man mercury, and mean to bring him fully under its influence. He takes three grains of blue pill each night. Not that I am trying to eradicate any syphilitic taint, for, in truth, we know of none in the case. But we know that mercury is a powerful drug and able to modify nutritional force very materially. We shall do our patient no harm with it. It may be that some of these obscure perversions of growth are evolutional forms of syphilis transmitted from infected ancestry, and so mercury, fully tried, may chance to be of special use. We know, at any rate, that in the peculiar form of systematic sclerosis of the posterior spinal columns known as tabes dorsalis—locomotor ataxia—syphilis plays a very prominent part, to the extent, indeed, of 80 per cent., or more, of all cases. Not that the lesion is itself directly syphilitic or gummatous, but that syphilis, as syphilis, seems to predispose to the particular form of sclerotic change in the cord which sets up the disease we know as tabes dorsalis. We are also maintaining the nutrition of this man's nervous system by cod-liver oil and a good diet. Nitrate of silver has been found of use in early stages of this disease. But for some time to come I should prefer to use mercury and iodide of potassium and carefully watch their effects, and I shall bring the results and the further history of this remarkable case before you on a subsequent occasion.

ON THE

SIGNIFICANCE OF A PECULIAR MURMUR IN RELATION TO THE DIAGNOSIS OF INTRA-THORACIC DISEASES.

By J. S. BRISTOWE, M.D. Lond.

(Continued from p. 837.)

Case 2. *Aneurysm of aortic arch; compression of both innominate veins, and communication between aneurysm and left innominate; great œdema and congestion of head and neck, and upper part of trunk; death; autopsy.*—Susannah F——, a married woman aged forty-six, was admitted under my care on May 27th, 1884. She has had moderately good health on the whole; has had one child, no miscarriages; has never had syphilis. Nine years ago she had typhoid fever, with two relapses, and was in hospital for nine months. Last winter she complained a good deal of rheumatism. About that time she first suffered from shortness of breath and palpitation. Five or six weeks ago the patient first observed swelling of the neck and about the eyes, and a little later she noticed some difficulty of swallowing, and first complained of aching pain between the shoulders. She has had some cough all along. The above symptoms have increased upon her up to the present time.

The face and neck of the patient are much swollen and œdematous, and the lips, cheeks, eyelids, and ears much congested; the swelling involves also the upper part of the chest and the shoulders and upper arms. The veins in the neck are greatly distended, and form large spongy masses just above the clavicles; the veins also in the upper part of the thorax, in front and behind, and about the shoulders, are much enlarged. There is no ascites, and no œdema whatever below the nipples. The lower extremities, indeed, are emaciated. She complains of dyspnœa, cough, and severe pain in the chest, more especially between the shoulders. Chest generally resonant, and breath-sounds normal, except at the base, where there is some crepitation. Cardiac dulness not increased in area; apex beats in sixth interspace, directly below the nipple; all over the cardiac area, and along the arch of the aorta, may be heard a loud systolic murmur, and also what by some is regarded as a diastolic murmur. The fact, however, seems to be that a peculiar prolonged murmur, commencing with the systole and continued through the greater part of the diastole, is audible over the aortic area and upwards to the right clavicle, diminishing in intensity as one passes from this region. The systolic portion of the murmur is loud, somewhat musical, and of uniform character during the whole of the cardiac systole; but the murmur is continued through and after the second sound as a kind of musical hum, which gradually dies away. The murmur is audible in the back, along the course of the aorta. There is no definite dulness or pulsation to be detected beneath the clavicles or in the course of the aortic arch. Pulse 88, equal in the two wrists, not jerky; respiration 24, but laboured; and when she coughs there is manifest stridor. Phonation natural; no sign to the laryngoscope of affection of the larynx. The liver extends an inch or two below the ribs, and is tender on pressure. The urine contains a trace of albumen. Nothing is noticeable with respect to the digestive functions. There does not seem to be any actual difficulty in the act of swallowing; no enlarged glands or tumours to be felt anywhere.

There is very little to be added to the above account, excepting that repeated examinations fully confirmed the observations above detailed. With occasional imperfect remissions she gradually got worse up to the time of her death. The dilatation of the veins in the neck, upper part of the thorax, and shoulders varied somewhat, but on the whole increased. The œdema also varied to some extent, but also on the whole increased; and latterly, partly in consequence of this, partly in consequence of the concurrent lividity of the surface, her aspect was most distressing—indeed hideous. Her face, neck, shoulders, and bosom became enormously swollen, her eyelids congested and closed, her nose buried in her cheeks, her lips thick and the lower one pendulous, with a huge double chin prolonged laterally to the lobes of her ears. Latterly, too, the œdema extended down the arms, and still later involved also the abdominal walls and vulva, and even the lower extremities; moreover, petechial extravasations appeared beneath the integuments of the face and neck and upper part of the back. The dyspnœa became aggravated, and she had for the most part to be propped up in bed, and slept in this posture with her head lolling forwards over her chest. Her cough was troublesome and paroxysmal, and was attended with more or less muco-purulent expectoration, and on two or three occasions with hæmoptysis. Deep breathing was always attended with stridor, but there was never any impairment of phonation or involvement of the vocal cords. The condition of the thoracic viscera, so far as we could ascertain, remained unaltered. There were never any clear local signs of aneurysm or other tumour; never any distinct proof of consolidation of lungs or effusion into the pleuræ; and the murmur at the base of the heart retained its characteristic features from first to last. It must be added, however, that the great œdema of the thoracic walls, and more especially the enormous bulk of the mammæ interfered more and more with physical examination of the chest. The pulses at the wrists remained equal; but it was noted once or twice that the left pupil was somewhat smaller than the right. No enlarged glands ever appeared in the neck or elsewhere, and no tumours of any kind in the abdomen. She complained usually of more or less pain in the upper part of the chest and between the shoulders, sometimes a sense of pricking, sometimes aching or cutting; and occasionally the pain extended down the right arm; less frequently down both arms. This pain was often severe enough to keep her awake. The breasts also became very painful. She never had any actual difficulty in swallowing, and for the most part took food fairly well. But she gradually got weaker; and during the last three or four weeks became very drowsy, at times being difficult to arouse, and when awake inclined to ramble. Her temperature throughout her illness was generally subnormal. She died on August 1st, on which day it rose to 100·4°.

Necropsy.—There was much anasarca and lividity, especially in the head and neck and upper part of the trunk. There were some hæmorrhages in the substance of the left *pectoralis major*. *Chest*: both pleuræ adherent, the adhesions being œdematous. Lungs dark-red and firm but crepitant everywhere, excepting the left lower lobe, which was quite collapsed. The bronchial tubes contained frothy mucus. The pericardium presented a small quantity of serum, and towards the base of the heart appeared thickened. The right side of the heart was somewhat enlarged, but on the whole the organ was little, if at all, above the normal bulk. The valves were all healthy. The coronary arteries presented patches of atheroma. An aneurysm about two inches in diameter sprang from the transverse arch of the aorta about three inches above the valves, and bulged towards the right. There was a little old laminated clot adherent to its walls, and the cavity contained also a little pale and coloured recent clot. The aneurysm pressed upon the innominate veins, without obliterating them, and communicated in front by two small round openings with the left innominate vein. The larger of these was about a line in diameter. The aortic arch was very atheromatous. The abdominal cavity did not contain any fluid. The liver was congested, and evidently in the early "nutmeg" condition. The spleen was large and firm. The kidneys were rather small, and somewhat granular on the surface. There were two small fibrous tumours connected with the outer surface of the uterus, which was retroverted. There were no urates in the right great toe-joint.

I need scarcely say, perhaps, that the case which I have just detailed, and of which whatever was mysterious during life is fully explained by the post-mortem revelations, was not only interesting to those who watched it, but presented difficulties to those who tried to interpret it. I must confess that my own diagnosis was erroneous. It was of course quite obvious that the patient was suffering from an intra-thoracic tumour, which, amongst other things, obstructed either the vena cava descendens or both innominate veins. It was quite obvious, too, that there was a loud murmur commencing with the cardiac systole, most intense at the base of the heart and over the manubrium, but audible even to the apex. As has already been pointed out, there were some differences of opinion as to the character of the murmur or murmurs. Some of my younger colleagues, men of ability and experience, held that there was a double aortic murmur, and consequently constriction and regurgitation at the aortic orifice. I always maintained that the murmur was single and such as it has been described above, and that, therefore, it could not possibly indicate simple disease at the aortic orifice; and my view was so far confirmed at the post-mortem that the aortic valve was found absolutely healthy. But dominated by the memory of my first case, I leant to the belief that the patient was suffering from a highly vascular malignant growth. I think now that what turned out to be the real condition of things ought to have presented itself to my mind; but it did not. I went down late to the post-mortem examination; indeed, it was supposed to be completed; and I learnt that the case was one of simple aortic aneurysm, associated with healthy cardiac valves. I at once pointed out that nothing had been discovered to explain the murmur which had misled me during the patient's lifetime, and turning to a very able clerk of mine, a high wrangler, I said, "Mackenzie, you are our greatest authority on acoustics and hydrostatics, and must help us to solve the riddle." He at once said, "Perhaps there is a communication between the aneurysm and a vein." I acquiesced, and straightway a careful examination was made among the scattered fragments, which resulted in the discovery that such a communication existed. Had I not fortunately been present at the autopsy an important fact in the case would have been wholly overlooked, and a clinical phenomenon of interest would have remained without satisfactory explanation.

(*To be concluded*).

CASES
ILLUSTRATIVE OF CEREBRAL SURGERY.

By WILLIAM MACEWEN, M.D.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

CASE OF LOCALISED ENCEPHALITIS AND LEPTOMENINGITIS.

Summary.—Patient admitted with impairment of power in left arm, accompanied by muscular twitchings and pricking sensations in some parts: lesion diagnosed to be in upper half of ascending frontal convolutions: trephining: membrane-like patch over surface of brain involving arachnoid and pia mater along with external surface of grey matter: blood infiltrated into substance of brain in ascending frontal convolution: removal: reimplantation of bone: complete recovery.

F. N——, aged thirty-six years, a miner, was admitted into Ward 21, Glasgow Royal Infirmary, on November 27th, 1883, complaining of weakness, inability to work, and certain symptoms which were referable to the motor centres.

History.—He had been in good health until August, 1883, when by falling downstairs he was rendered unconscious, in which state he continued for about twelve hours. There had been a little blood about one of his ears, but whether this came from a superficial abrasion or was indicative of a more serious condition could not be ascertained. When he regained consciousness he found himself to be quite well, with the exception of experiencing a giddy sensation when he attempted to walk. He could move his arms and legs freely, he had full possession of sight, hearing, taste, and smell, and he believed himself to have quite recovered from his fall. Soon afterwards he attempted to work, but found that he was too weak to do so, and as time passed, instead of getting stronger he became weaker, and he therefore sought medical aid. He ultimately came to Glasgow, and was admitted into the medical wards of the Glasgow Royal Infirmary on September 18th, 1883, eighteen days after the accident. From the resident assistant the following was learned concerning his state at that time. He had partial right-sided facial paralysis. It was not clear whether this paralysis was due to a cerebral or a peripheral cause—some interference with the facial in its course through the temporal bone. Though the patient complained of weakness, no impairment in sensation or motion was detected over the trunk or limbs. He was treated by a series of blisters over the temporal region and rest. When he left the medical wards there was an improvement in the state of his face, though he remained otherwise in much the same condition. After getting home he repeatedly attempted to work, but found that he was quite unable to do so—first, from a feeling of general weakness; second, from a feebleness in the left arm; third, from a vertigo which came over him when he assumed the upright position, after stooping, or when he made any sudden movement; and fourth, from a general sensation of oppression, which he referred to his head. He also found that he was falling off in flesh. Some time afterwards he sought admission, on the advice of his physician, to the surgical wards of the Royal Infirmary. He was admitted to Ward 21 on Nov. 27th, 1883, twelve weeks and four days after the accident, his condition then being as follows:—He was a tall strongly-built man, having a shrunken and careworn aspect, his features being rather pinched. There was a trace of right-sided facial paralysis evinced by a slight passivity of expression, which was confirmed when he attempted to elevate his eyebrows. Occasionally the muscles on the right side of his face twitched. The pupil of his right eye was sluggish, responding feebly to light, so that when exposed to the full light of the window, it only contracted to about half the extent of its fellow. There was no external mark of injury on his head, though he complained of a feeling of weight and oppression in it, which, however, was diffuse. The muscles of his arms were well developed, though soft, and those of his left arm seemed slightly wasted. The power of grasp of his left hand was very feeble. The muscles of his left arm were frequently spasmodically jerked, and he experienced pricking sensations from the shoulder down to the fingers. He preferred not to hold anything breakable in his hand, because he said that "he could not trust it," as he was liable to drop anything which he might have in it. Though he had this want of confidence in his hand, he did not let anything fall while under examination. The condition of the arm as to want of power and the twitchings in the muscles were becoming steadily worse. When he stooped and rose quickly and then tried to walk he staggered, and he said that he felt giddy for some time afterwards. His temperature was occasionally slightly above normal. His lungs, kidneys, and other organs were sound. The head was shaven and another examination was made, but no sign of injury or abnormal irregularity could be detected.

From the history, as well as from his condition at the time of the examination, it was obvious that there was a lesion of the motor cortex in the upper half of the right ascending frontal convolution. As to the pathology, it was probable that irritation had been set up round an extravasation of blood which had taken place into the brain cortex at the above point as the result of a cerebral contusion. From the time that had elapsed since the injury, the extravasated blood would have undergone secondary changes, and it was probable from the increase and progress of the symptoms described as affecting the left arm that the irritation was of an inflammatory nature, although there was no pus production—a localised encephalitis, and probably a leptomeningitis. The former facial paralysis was probably due to an injury of the nerve, and not to a central cause. As counter-irritation had been employed for a considerable period without effect, it was not deemed expedient again to have recourse to it, more especially as it could not influence the blood effused. Dr. Robertson was asked to see this patient, and quite concurred in the diagnosis, and in the necessity for operative treatment. The patient was very desirous that something should be done to alleviate his condition, as he found himself totally unfitted for work, and felt that he was daily becoming worse. When it became known to him that his brain might be operated on for the relief of his symptoms, he eagerly begged that it should be done.

Operation, December 8th, 1883: The patient was placed under chloroform and a portion of the right parietal bone was removed, about one inch behind the auriculo-bregmatic line, and one inch above a line drawn from the external angular process of the frontal to the upper angle of the lambdoidal suture. A circular portion of skull was elevated one inch in diameter, exposing the middle of the ascending frontal and parietal convolutions. The disc of skull elevated was somewhat thinner than usual, and its internal table was slightly eroded. The dura mater, instead of presenting its usual smooth glistening appearance, had an irregular roughened surface, and was of a yellowish-grey colour, with here and there a dark patch indicating blood-clots in the subdural space. It was closely adherent to the skull round the margins of the trephine aperture. A crucial incision was made into the dura mater, when a considerable quantity of clear fluid along with some clots of blood about the size of a large bean escaped. Other clots had to be removed, as they were adhering to the structure underneath. After taking away these clots there were no brain pulsations visible, and the surface which then presented itself was of a somewhat yellowish colour, having an opaque dense aspect, and being adherent to the tissues underneath. This membrane-like patch lay chiefly over the ascending frontal convolution, dipping down into the fissure of Rolando. An incision was made through this layer, when it was seen to be about an eighth of an inch in thickness, and to be probably composed of the arachnoid, pia mater, and the superficial portion of the cortex, all of them fused together by plastic exudation, so as to resemble a single dense membrane, the various layers of which could not be differentiated. The underlying brain tissue in the upper part of the ascending frontal convolution was infiltrated with minute blood-clots, some of them about the size of a pea, others that of a barley grain. Till this incision was made through this membrane-like patch into the brain substance there were no pulsations visible; but when this was done the pulsations became distinct, and at the same moment many of the little clots, along with a quantity of serum, became extruded from the brain tissue, many of them coming from some depth, apparently helped to the surface by the cerebral pulsations. These clots were of a yellowish-brown colour externally, and when broken their interior was still black. A short time was given to permit the brain impulses to complete this extrusion, after which, as a few clots could still be discerned in the interior of the brain, they were gently loosened, when they were quickly extruded by the same movement. After all the clots were removed, a minute vessel on the brain surface continuing to bleed, pressure was exerted for a minute, which completely occluded it. The brain substance at this part seemed softer than normal, and was of a yellowish-brown colour. The dura mater was replaced, and the disc of bone which had been removed, and which had its periosteum entirely stripped off, was divided into several portions, and reimplanted in the aperture in the skull, a small opening being left at the side for drainage. The scalp was brought together with chromic gut, a decalcified chicken-bone tube being placed between the scalp and the skull for drainage. The entire operation was done under the carbolised spray, and eucalyptus dressings were applied. Forty-eight hours afterwards the wound was redressed, when a slight blood-stain was found on the dressing. Three weeks afterwards the wound was examined for the second time, and found healed. The patient's highest rectal temperature was 100·4° F. He never had a bad symptom, felt perfectly easy, and the only difficulty experienced was in persuading him to remain in bed, and in preventing him from indulging in other than low diet. The skull was firm over the trephine opening, into which the bones had been reimplanted. At the end of forty-eight hours there was almost a paralytic state of the left arm; he could not move the fingers. At the expiration of a week, when the arm was permitted to be examined for the second time, this had quite gone. His fingers were moved freely, and he could raise his arm and flex all the joints freely. From the third day after the operation there were no jerkings in the muscles of the arm. At the end of six weeks he had improved greatly in strength generally, and he declared that his left arm was as strong as ever; certainly it had gained greatly in strength. He was now eager and anxious to be permitted to get out to work. He was dismissed at the end of two months. Eight months afterwards he reported himself as regularly at work and in excellent health, the power of his left arm having been quite restored.

(To be concluded.)

A CONTRIBUTION TO THE

CLINICAL STUDY OF THE LIVER VIEWED THROUGH THE URINE.

BY GEORGE OLIVER, M.D. LOND.

(Continued from page 840.)

No. II.—THE PHYSIOLOGICAL AND CLINICAL ASPECTS OF THE BILE SALTS IN THE URINE.

I. *The bile salts are increased.*—My clinical experience has demonstrated an excess of biliary salts in the urine in the following morbid conditions:—

1. *Jaundice.*—Authorities are divided on the question of bile salts in the urine of jaundice, some (such as Frerichs, Städler, Murchison) holding that they are invariably absent, believing that they are decomposed by the blood; others (Kühne) always detecting them, whatever the form and the duration of the jaundice, and others (George Harley) asserting the presence of them in all cases of obstructive jaundice, while, in fact, bile is being secreted by the liver and absorbed into the blood, but failing to discover them when the liver, from disorganisation, ceases to secrete bile. All this diversity of opinion must, I think, be referred either to the defectiveness of the processes hitherto employed for the separation of the bile acids from the urine, or to the want of a clinical test of sufficient accuracy and delicacy. So far my experience agrees with that of Kühne; for I have invariably found an increase, and generally a very decided increase, of the bile salts in all forms and stages of jaundice; this even in cases of from one to four years' duration. According to my experience of jaundice, the bile salts are not only apt to appear in the urine in increased quantity before the appearance of bile pigment, but to persist for some weeks after the urine has become quite free from it. In several cases I have found the peptone test of considerable practical value in affording an early intimation of the presence of conditions favouring jaundice, which was apparently averted by prompt treatment. Only lately I came across such a case, when I expressed a fear that jaundice would follow; I was then told that the patient was jaundiced under like circumstances six years ago. A full dose of calomel and colocynth followed by sulphate of magnesia, however, brought away a large quantity of what had all the appearance of pent-up biliary matter, and the patient gradually convalesced without the supervention of jaundice, the urine the while presenting a diminishing charge of bile salts, until at last it became quite normal, and the fæces assumed a healthy apperance. The test has also proved useful in my hands in indicating when a case of jaundice, after the ordinary bile flow into the bowels has taken place, may be considered fairly out of the wood, and when the liability to relapse may be regarded as unlikely. This pale urine was passed by a patient six weeks after the bile appeared freely in the evacuations. Yet it contains, as you observe, over 100 per cent. increase of the biliary salts. The patient is now, however, quite well.[1]

2. *Functional disorders of the liver: biliousness.*—The bilious may be broadly divided into two classes—namely, those in whom the liver is loaded with biliary products, either from habitual per-secretion, or from an accumulation of them, which is less or more constant, or is only occasional; and those in whom the secretion of bile is always below the average—sub-secretion.

Acute biliousness.—Those who always "make" bile, as well as those who suffer from biliary engorgement due to defective excretion, &c., are prone to "hepatic storms" or periodical overflows of bile either into the bowels or the blood, or into both; as when there occurs a sudden alteration of arterial tension,[2] as a rise from excitement, or a fall from chilling or other meteorological influence, or when a dietetic error is committed. Then, when the bile derivatives are absorbed too freely into the blood, as they generally are, the symptoms resemble those of acute poisoning by small doses of the bile salts in animals—namely, feeble pulse, pallor, coldness of the extremities, and a feeling of chilliness throughout, from imperfect filling of the arterioles; slow, sometimes gasping breathing; nausea and vomiting, and occasionally diarrhœa. In migraine these symptoms, which characterise the ordinary forms of acute poisoning by the bile salts, are overshadowed by the painful disturbances of the fifth and of the optic nerves; neurotic effects which *may* spring from the same central cause; but in these cases the attack is probably preceded or accompanied by an arrest or a diminution of the renal elimination of the biliary salts, followed by an augmented discharge which affords immediate relief.[3] In an ordinary attack of acute biliousness the bile salts flush the blood and are eliminated in increased quantity, and more particularly so towards the close of the disturbance. Acute bile-acid poisoning may, however, go beyond the stage implied by the ordinary bilious attack; it may even become so intense as to induce convulsions—which, however, as a rule, subside as the suddenly induced excess of the colourless bile product in the blood is cleared away, either by the kidneys, or by the bowels or by the skin; such a severe disturbance is apt to follow an excessive indulgence in alcohol, or the taking of some indigestible article of diet, or of too large a meal.

Chronic biliousness is also a cause of an increased systemic diffusion of bile salts, and the excessive renal elimination of them. Then the disorder is, as a rule, not purely functional, but depends on hepatic congestion induced by alcohol:[4] the initial stage of cirrhosis, by too good living, or by some obstruction to the portal circulation, as in heart disease, or by the congestive effects of malaria on the liver and spleen. Cases of chronic biliousness are, however, now and then met with which, though providing an excess of bile salts in the urine, do not exhibit the ordinary signs of hepatic congestion, and are not referable to the causes just indicated. But chronic biliousness perhaps, in the majority of cases, arises either from subsecretion of bile or the retention of biliary elements in the blood. When constipation is a prominent feature in a case of biliousness, as it frequently is, the bile salts will be detected in greater excess than when the bowels are regular or free; and this is not surprising, for constipation means retention of bile about the portal system, favouring as it does a retarded flow in the bile-ducts and absorption of cholate of sodium contained in the contents of the small intestines and in the fæces.[5] In any case of hepatic disturbance whenever the edge of the liver is to be felt below the margin of the thorax, and is sensitive to the touch, or when, without obvious enlargement of the liver, the fingers pressed well under the lower right ribs elicit tenderness, bile salts in excess will in all probability be discovered in the urine. But, on the other hand, these constituents are frequently found in excess without there being any tenderness of the liver. In chronic biliary derangement I have frequently found the bile salts in greater excess in the urine voided during the period of digestion than in that discharged before meals—e.g., two hours after breakfast than on rising. The urine of hepatic embarrassment, producing acute and chronic biliousness, is that of subjaundice—a minimal form of jaundice, which, like the major form, is characterised by a surcharge of bile derivatives in the blood and the elimination of them by the kidneys, but differs from ordinary jaundice in furnishing urine which not only contains a smaller proportion of bile elements, but always presents an excess of the biliary salts, while it is only occasionally pigmentous.

---

[1] According to my observations, jaundiced urine is but a portion of the large group of urines containing biliary matter in pathological problems. Hence I venture to use the term "choluria," in order to [illegible] indicate the presence of the colourless bile elements in abnormal quantity in the urine.

[2] Variations of arterial and venous tension disturbing the biliary secretion is a matter of interest in practical medicine. The physiologist knows that the secretion of bile is increased by injecting blood into the veins, and diminished by bleeding or by compression of the aorta, and by obstructing the portal vein. All this has an important bearing on the pathological phenomena of the liver and the treatment of them. How often does a judicious attempt to raise the arterial tension in subcholia do more good than the whole battery of cholagogues, the poor anæmic liver rising to a higher standard of work in proportion as its blood-supply is improved?

[3] During the course of an attack of migraine I am inclined to think, from what I have observed, that there is in the typically neurotic forms of this ailment a check to elimination; then there occurs a flush by some channel—such as that of the kidneys, the skin, or the bowels—which brings heavenly freedom from the grip of the enemy. Sleep in many cases, and remedies addressed to the neurotic state in others, favour the freedom. This is a large subject, and can only be lightly touched in passing.

[4] I have found the peptone test very useful in detecting the abuse of alcohol. It would seem as if the urinary bile salts rise in quantity in the early stages of hepatic congestion from alcohol—in fact, before any enlargement can be made out or any tenderness can be detected.

[5] I have, however, every now and then discovered a decided excess of bile salts in the urine in cases of biliousness with free alvine evacuations, these being quite loose and bright-yellow, as if the biliary elements overflowed into the blood as well as into the bowels.

3. *Diseases of the liver apart from jaundice.*—I have found an excess of bile salts in the urine of carcinoma, amyloid disease, enlargement of the liver generally, cirrhosis, and in that of tumours probably hepatic. In passing diseases of the liver, such as hepatitis, I am disposed to think the peptone test will prove of some clinical value in showing when the liver has become completely restored.[6]

4. *Diseases of the spleen.*—In several cases of choluria the liver was enlarged as well as the spleen, but in two the enlargement was confined entirely, or almost entirely, to the spleen;[7] but notwithstanding the absence of definite hepatic disease, the bile salts appeared in the urine of these cases in large excess, associated with a little albumen, and they were not accompanied by bile pigment. Here is a good specimen voided by a patient under treatment; it is not pigmented, and it contains 300 per cent. increase of bile salts; the patient has a large spleen from ague, but he has no hepatic enlargement; in fact his liver appears to be below the normal size. This clinical fact appears to me noteworthy in connexion with some experimental data bearing on the relative amount of bile salts present in the splenic pulp and in the parenchyma of the liver, which will appear in the addendum to this paper.[8]

5. *Fever.*—A rise of temperature from whatever cause always induces a systemic excess of bile salts. With a temperature of 104°, and without any suspicion of liver affection, I have known the renal elimination to exceed 400 per cent. increase over the normal standard. Even a slight rise, such as that of 1° or 2°, increases the renal discharge of these elements. I need scarcely mention the intimate pathological connexion that subsists between the turgescence and consequent activity of the spleen and fever. This fact, viewed by the side of the urinary excess of bile salts in fever as well as in splenic disease apart from fever, is interesting when we attempt to take into consideration the probable causes of the prominent symptoms of the febrile movement, especially the prodromal ones. Some, such as chilliness and even rigors, nausea, vomiting, diarrhœa, epistaxis, convulsions, and the miniature clonic contractions of subsultus tendinum, I am disposed to refer to an excessive charge of bile salts in the blood. But how are the rheumatic symptoms — aching of the back and limbs, severe muscular and even articular pains—to be accounted for? The spleen also suggests an explanation, for according to physiological observation it would seem as if the splenic pulp were the birthplace of uric and other organic acids—such as lactic, acetic, butyric, formic, and succinic. In connexion with this point perhaps I should state that on using a sensitive litmus paper I have always found the splenic pulp of the freshly killed animal distinctly acid; and the same observation applies to the human spleens, which I have examined twenty-four hours after death, and to the recent decoctions of spleens and livers of man and animals.

6. *Hæmolytic diseases.* — Dissolution of the blood—and especially of red discs—obstruction of the capillaries, and hæmorrhages are prominent facts in the poisoning of animals by injecting bile salts into their veins. On turning to clinical experience we find the counterpart of these experimental data.

(*a*) *Anæmia.*—In anæmia the balance, which in health is maintained between the generation and the destruction of the blood-corpuscles, is disturbed. There would seem to be either a failure in the hæmogenesis, or an increase in the hæmolytic process; determining, as the case may be, a hæmogenic or a hæmolytic form of the ailment. Probably the defect is generally on the side of construction; but I have met with several instructive examples of the hæmolytic type, in which there was a considerable excess, pretty regularly and persistently maintained, of bile salts in the urine; then it was that some attention to the portal organs was indicated, and was of greater service than the ferruginous treatment of the blood state, the pernicious work of the liver apparently causing the failure. I suspect that arsenic is a valuable remedy in some of these cases of hæmolytic anæmia; purgative doses of the sulphates are certainly useful. The following figures indicate the range of increase of the urinary bile salts which I have recorded in this form of anæmia: 400, 300, 60, 100, 300, 60, 60, 400.

As yet I have not had opportunities of studying, in connexion with the bile salts, *pernicious anæmia* and *progressive anæmia*, which has a *primâ-facie* resemblance to the pernicious form.

In *splenic leucocythæmia* there is a large excess of the biliary salts in the urine. Here is a sample of the urine of a case in the London Hospital; it has a specific gravity of 1009, and contains a little albumen, and you observe that it is quite pale, free from biliary pigment, and that it is charged with as much as 750 per cent. increase of the bile salts, for eight minims of it produce the same degree of opacity with sixty minims of the peptone solution as do sixty minims of healthy urine.

In *malarial anæmia* (in cases even that did not present recognisable enlargement of the liver or spleen, or other organic changes) I have found a marked increase. This is the urine of a case of malarial anæmia in the Charing-cross Hospital; it contains, as you observe, over 300 per cent. increase of the biliary salts.

(*To be continued.*)

CASES OF LITHOTOMY IN THE ADULT,

WITH REMARKS.

BY WALTER RIVINGTON, F.R.C.S. ENG., M.S. LOND.,
SURGEON TO THE LONDON HOSPITAL, AND LECTURER ON SURGERY AT THE LONDON HOSPITAL MEDICAL COLLEGE.

CASE 1. *Four large calculi and one small one removed by the median operation.*—Stephen H——, thirty, a well-made man, was admitted into the London Hospital on Dec. 19th, 1871, in a very critical condition. At first he affirmed that his illness only dated back for four or five weeks, but subsequently, on cross-examination, it was ascertained that suspicious symptoms had existed for some years. Occasionally, after exertion, blood was found in the urine, and at varying intervals he was obliged to lie up for a few days; a bottle of medicine, however, soon set him right. For some time he had experienced an itching sensation at the end of the penis. When he ran about or jumped he felt "something move in his inside," and such exercise was followed by the appearance of blood in his urine. His urine never stopped suddenly while micturating, but he had often felt pain after the act was completed. The pain would extend round his loins, and his testicles would be drawn up. Five weeks before admission he caught cold. He then noticed a discharge from his urethra, and, finally, he suffered from retention, for which he was attended by his club doctor. He had retention four times before admission, and on each occasion a catheter was passed. His urine was exceedingly thick, so that, according to his own account, "you could stand a stick up in it." On one occasion blood came away when the catheter was introduced.

---

[6] In the discussion which followed the reading of this paper, Dr. Clifford Allbutt related the case of a convalescent from hepatitis sent to him for his opinion as to the recovery of the liver, and the advisability or otherwise of the patient's return to his employment. "On using the peptone test," said Dr. Allbutt, "a large precipitate appeared, and I felt justified by the information thus provided in reporting against the complete restoration of the liver, and in advising a further reprieve from work."

[7] Of course splenic enlargement does not necessarily imply increased activity of splenic function. As this paper is passing through the press I come across a good example in a patient of Dr. Ward's, of Harrogate. There was no choluria, though the spleen was found post mortem considerably enlarged; the portal and splenic veins were embedded in a mass of matted-up and thickened glandular tissue, and were clearly obstructed, for no blood issued from the portal vein on section; the liver was highly anæmic and fatty, the bile-ducts were entirely bileless, and a decoction of the parenchyma of the liver afforded a mere trace of bile salts. This case was, as it were, a beautiful and neat experiment planned by the hand of nature to shut off the products of spleen work from the liver and the systemic blood.

[8] Inasmuch as in experimentation with bile salts injected into the veins of animals the serum becomes loaded with fatty molecules, it is interesting to note some observations on this point in various cholæmic diseases, made by competent observers long before the cause of the fatty serum was apparent. Traill, over forty years ago, remarked on the creamy or milky serum of hepatitis, and on several occasions showed that the turbidity was due to a large quantity of fat. In inflammation of the spleen (lienitis) the serum was observed by Cullen, Testa, and Heusinger to be turbid from fatty matter. Simon, in his "Animal Chemistry," gives many interesting analyses of the blood of fevers, inflammations, jaundice, &c.—all these being cholæmic diseases—showing an excess of fat. Then, again, in leucocythæmia (another cholæmic disease) the blood is distinctly increased (Robertson and Isambert).

Ten days before he came to the hospital he had a rigor, which lasted half an hour.

On admission he was found to be the subject of phimosis. The end of the penis was acutely inflamed, very œdematous, and displayed one or two blackish sloughy points. A muco-purulent discharge issued from the urethra. His urine was passed very frequently in gushes and had a highly ammoniacal odour. It was tinged with blood, had an alkaline reaction, and a specific gravity of 1012, and contained a trace of albumen, epithelium, blood, lithates, phosphates, and pus. He had little, if any, suspicion that he was the subject of a serious affection of his urinary organs. His belief was that he would be well in a day or two, but his aspect belied it. His countenance wore a very anxious expression; his lips were covered with herpetic spots; his tongue was dry, brown, and coated. He was thirsty and feverish. Pulse 120. Temperature 101·6°. A No. 6 silver catheter passed by the house-surgeon, Mr. Beech, into the bladder was so firmly gripped that it could not be rotated. On its withdrawal a clot of blood issued from the urethra, followed by a mass of yellow gelatinous matter. He was ordered a warm bath, and he said it "did him a deal of good," as it brought away a quantity of urine and muco-purulent discharge. On further examination I found that the catheter grated over something rough in the urethra beyond the triangular ligament, and with the forefinger in the rectum I detected a hard body just in front of the prostate, not appreciably movable. This was diagnosed as a stone which had escaped from the bladder and become impacted below the urethral canal.

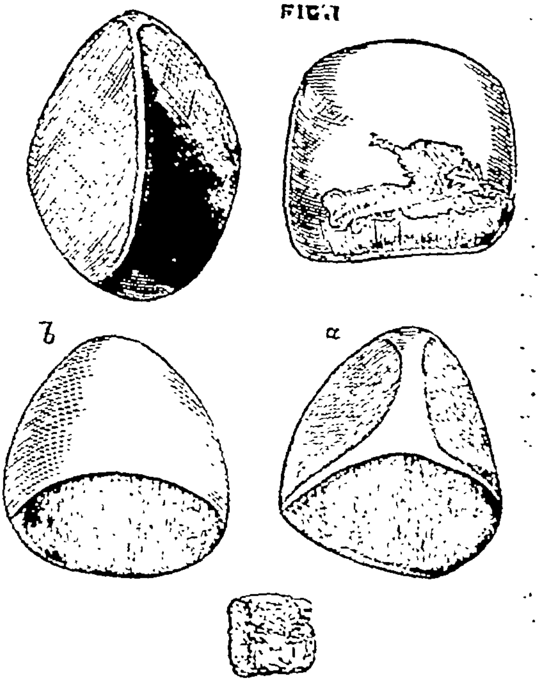
On December 20th Mr. Hutchinson saw the patient with me, and it was deemed advisable to undertake an immediate operation as affording him the best chance of recovery. Accordingly the patient was taken to the operating theatre and placed under the influence of chloroform. The staff was taken by Mr. Hutchinson. I opened the urethra by a median incision, introduced a pair of urethral forceps, and readily extracted a small stone. My fingers passed forwards into the prostate gland, hollowed out by the destruction of its tissue, and, reaching the neck of the bladder, came into contact with some larger stones. Mr. Hutchinson, who also examined the parts with his fingers, remarked that there was "a quarry." The presence of other stones had been indicated by smooth facets on the small stone first extracted; a pair of forceps was introduced, but as the stones were large, it was found necessary to enlarge the wound in the urethra. Then I extracted the stones in quick succession, washed out the bladder, and introduced a sponge-tube. The mucous membrane of the bladder appeared to be much thickened. There was very little hæmorrhage during the operation—none afterwards.

On the following day (Dec. 21st) the patient appeared to be much better, and expressed himself as comfortable and free from pain. He had had a good night, and was sanguine of a speedy recovery. The tongue was still dry and brown; the pulse about 130; temperature 100·5°. Some urine passed by the natural route.—22nd: Much better, and thought he could eat some chicken and oranges, which were ordered accordingly. Had slept well during the night. Bowels opened freely. The tenderness over the hypogastric region which had existed before the operation had disappeared. Urine passed through the penis. Pulse 130; temperature 100·5°.—23rd: Had passed a good night; said he could eat more. Urine still thick, some coming through penis and some through tube. Pulse very quick and weak; temperature 100° to 102°.—24th: Tube removed. Not so well. Had passed a good night, but perspired a good deal, and a profuse purulent discharge issued from the urethra; mouth very dry and parched; countenance anxious; pulse could scarcely be counted; temperature 102° throughout the day. In the afternoon he rallied, took his food again, and had a long sleep.—25th: Not nearly so well; had a disturbed night; breathing quicker and shorter; pulse still very small and rapid; countenance anxious with rather a vacant stare. In spite of the urgency of his condition he ate a hearty dinner at one o'clock. During the afternoon he became worse, and died at 11.55 P.M.

He had no rigors after the operation. He was sick once soon after it was over, possibly from the chloroform, and once the next morning. The other symptoms were fully explained by the condition of the urinary organs found after death.

Necropsy.—On opening the abdomen Dr. Sutton said that the peritoneum had a greasy appearance, and pointed out a red congested line on the edge of the intestinal coils, especially apparent in the upper part of the abdomen. These he regarded as indications of impending peritonitis. There was not, however, any trace of effusion into the peritoneal cavity, and the peritoneum covering the back of the bladder and the front of the rectum retained its natural lustre. The bladder was contracted. Its mucous membrane was much thickened, highly pigmented, and of a bluish-black colour with here and there whitish patches as if due to the deposit of phosphates from the urine which had been loaded with them during life. The muscular tunic was thickened. The prostate was hollowed out into a ragged cavity containing purulent matter, the floor of the urethra and the veru montanum being destroyed. Some pus was found in the fascia bounding it on the left. The left ureter was very much dilated, about three-quarters of an inch in diameter, and opened into the bladder by a wide orifice in the centre of a large papillary eminence which projected into the bladder, and apparently resulted from chronic thickening of the mucous membrane and the muscular fibres connected with the duct. The mucous membrane lining the ureter and pelvis of the left kidney was thickened and the seat of pigmentary deposit. The pelvis of the left kidney was much dilated, and the infundibula and calyces could be traced outwards, forming a number of culs-de-sac encroaching on the cones. These pouches and the pelvis itself were full of thick gelatinous, muco-purulent matter. The cortex was in a state of atrophy. The right kidney presented in a minor degree appearances similar to those in the left. The cortex was contracted, two of the cones obliterated and muco-pus was found in the pelvis and calyces. The right ureter was only slightly larger than the left. The lungs were much congested and emphysematous. The pericardium was healthy. The left ventricle was firmly contracted. The brain was healthy. The annexed woodcut (Fig. 1) will show the size of the calculi. Their united weight on removal was two ounces and three-quarters. In each of the large calculi there is a nucleus of urate of ammonia mixed with a large proportion of oxalate and urate of lime. Upon this is deposited phosphate of magnesia and ammonia containing a small quantity of phosphate of lime. The outer layers consist chiefly of phosphate of lime alternating with thin layers of urate of ammonia. The central portion of the large calculi resembled in appearance, structure, and size the small calculus. The exact similarity of structure shown by the calculi may possibly indicate that all the four larger ones were formed simultaneously. The calculi are in the museum of the Royal College of Surgeons of England.

FIG. 1



Remarks.—A noteworthy feature in the foregoing case is the slight amount of constitutional disturbance and local pain or discomfort occasioned by the calculi. They must have been in the bladder for some years; and it was not till the smallest one descended, entered the urethra, caused destruction of the prostate and ulceration of the urethra, that sufficient inconvenience was occasioned to necessitate admission into the hospital. There was no evidence of the patient ever having been sounded, or the existence of calculi suspected by his previous medical attendants; and he was admitted in a most precarious, and, as the issue proved, a hopeless condition. The kidneys had already been greatly damaged and the secreting structure spoiled by backward pressure and chronic inflammation, and an abscess had formed in the pelvic fascia outside the disorganised prostate gland. Had the calculi been found a few months earlier, in all probability a fatal result might have been averted. As the case stands, the death cannot in anywise be attributed to the operation, which was in every way beneficial. It placed the patient in a condition of comfort and ease, although unavoidably it came too late to be of permanent advantage.

(*To be concluded.*)

CASE (UTERINE) ILLUSTRATING THE ACTION OF DIGITALIS AS A DEPRESSO-MOTOR.[1]

By J. GORDON BLACK, M.D. Lond.

We are all no doubt agreed as to the great value of digitalis as a cardiac stimulant and contractor of the arterioles, and in materially increasing the blood-pressure in all parts of the circulation. Probably no day passes without our feeling thankful for the aid which this useful drug affords when various little peculiarities of its action are thoroughly understood. As a depresso-motor, however, having a special power over the inhibitory reflex ganglia of the spinal cord, I fancy digitalis is not so generally employed. About twenty years ago, I remember seeing cases of delirium tremens treated with large, or what one may call depresso-motor, doses of digitalis. For example, half an ounce of the tincture would be given several times during the day or night, and had an excellent calming effect upon over-excited nerves and exhausted reflex centres. No doubt this method of administration is familiar to all; but judging from my own experience such a use of the drug is more occasional than common. Perhaps there is a latent dread of untoward effects, and thus one prefers to use the more familiar bromide of potassium or hydrate of chloral to control the disordered reflex manifestations. The following case seems happily to illustrate the power of digitalis, even in comparatively moderate doses, to stimulate exhausted inhibitory centres.

About two years ago I was sent for, late one night, to see a young married lady, staying in lodgings with her husband. Before reaching the house I heard shouts and screams, which I was told emanated from the patient. I found her in bed, throwing her arms and limbs about in a state of the wildest maniacal excitement. At the top of an unusually loud voice she was ordering her husband, or the maid, to get her beer, brandy, or morphia by turns. Had it not been for one symptom which arrested my attention in the act of walking across the room to the bedside on my entrance, I should certainly have felt inclined to ascribe the appearances before me to alcoholic excess. The emphatic signal which, however, at once awakened all my medical sympathies was that of well-marked risus sardonicus—the ghastly grin of the baboon, with the angles of the mouth drawn downwards and outwards, as if by tightened cords. Here was, therefore, no ordinary case of drunkenness or alcoholic mania, but one in which the fountains of the nervous system were seriously implicated. But for this invaluable hint the diagnosis, amid the incongruous surroundings of the sufferer, would have been a labour indeed like unravelling the Gordian knot. Hysteria there was of the most pronounced character. The patient had been addicted for upwards of two years to the hypodermic use of morphia. It had been originally ordered by a medical man for the relief of severe hypogastric and inguinal pain. There was now hardly half an inch of space down the outer side of one lower limb, from the hip to the ankle, where the morphia needle had not penetrated. She even boasted of her skill in operating without leaving a mark on the skin.

Such was my introduction to a very uninviting and apparently hopeless case. The utter degradation and loss of moral restraint in a woman, whom I afterwards found to be a lady of delicate sensibilities and proper conduct, could only be appreciated by actually looking "on this picture and on that." The patient was about twenty-nine years of age, and had been married ten years. She had been twice pregnant within the first two years of married life, but miscarried on each occasion at about the eighth month. The menses had always been regular up to four months ago, since which time they had not appeared. To make a long story short, I discovered that the whole train of symptoms in this case depended upon complete retroversion and flexion of the uterus, which organ was literally upside down, with an acute flexion about the site of the inner os. During the first twelve months of my acquaintance with this confirmed invalid the following forms of hysteria presented themselves at various times to my notice: double wrist-drop, so that splints down the arms were necessary to support the useless hands; loss of power to flex the body upon the lower extremities (she was thus unable to raise herself in bed from the lying into the sitting posture, and although she could sit when placed in a chair, by no effort could she stand up); intense salivation, with swollen gums and tongue, accompanied by horribly fetid breath; absolute aphonia for many days, followed by very considerable paralysis of the muscles of inspiration, the latter at one time being so serious that quantities of mucus collected in the bronchial tubes and trachea, causing the patient much anxiety from fear of impending suffocation; finally, the occurrence of an attack of catarrhal croup of unmistakable character.

Now, in this case, the only drug which seemed to possess power enough to control the disturbed action of the nerves and the maniacal symptoms was morphia. Under its soothing influence she was indeed happy and reasonable. So soon, however, as its effect had passed off she became a raving lunatic, disturbing night and day the neighbourhood where she lived, and for whom the appliances of a madhouse were devoutly desired by her medical attendant. Other medicines, such as the bromides, hydrate of chloral, chloroform, belladonna, quinine, tincture of iron, &c., were next to useless. I never knew bromide of potassium, even given in large doses, prove so utterly powerless. The patient was by no means a dipsomaniac; but, at times of excitement, alcohol was too freely taken in order to drown the sensations of nervine horror which enthralled her. To this end, however, it was only very partially successful; perhaps a little more so than the medicines just enumerated. Immediately on rectifying the malposition of the uterus, complete relief to the most distressing symptoms was attained. Whenever the womb was straightened and duly erected into a normal attitude, by means of a Graily Hewitt's stem pessary, the patient became a reasonable, controllable being, however outrageous her previous conduct might have been. This sequence, as cause and effect, was abundantly verified during the early treatment; for of course at first it was no easy matter to adjust an instrument capable of maintaining itself against the tension of ligaments and tissues contracted by long-standing error. Accidents would occasionally happen, and several times I found that the uterus had actually carried the pessary with it into an inverted position, the point of the stem being vertically downwards, whilst the base of the instrument was wrong side upwards. Under such adverse circumstances, the patient was evidently conscious of something having gone wrong, and very soon afterwards the characteristic risus sardonicus and the dreaded maniacal outbursts supervened, with a horror and thraldom upon her nervous system such as the sight of a spectral appearance might have caused. Under the mechanical uterine treatment mentioned this patient became practically well in the course of six or eight months. She was enabled to throw off the invalidism of several years' standing, and to walk abroad once more.

Thus far I have been obliged to describe this case in order that what follows as to the action of digitalis may be fully understood. About five months ago—that is, a year and a half after my first introduction to the patient, I was sent for one afternoon, in a hurry, to see her. On arrival, I saw again, to my intense chagrin, the spectral ghastly grin, maniacal rolling eye, and the furtive glance so well remembered; and though, as yet, the shouting demeanour was absent, there was the whispered entreaty for morphia, which she had not used for more than eighteen months. As if this were not discouragement enough, I discovered, upon vaginal examination, that the stem pessary which she continued to wear was not this time out of order. It was in perfect apposition, and erect in attitude. Independent of the treatment by pessary, nothing but morphia had been found able to moderate the violence of these outbreaks; and the employment of morphia I had rigidly forbidden on account of its pernicious effects on her constitution, moral and physical. The day was far advanced and night coming on, with the prospect of the household being turned into a veritable pandemonium. On casting about for some cause for this unpleasant return of her tormentor, I learned that the menses had been rather suddenly stopped by a chill. The left inguinal region was tender to the touch, whilst the left ovary, per vaginam, was felt to be swollen, and the slightest pressure over it was acutely painful to the sufferer. Here, therefore, appeared to me sufficient cause for the nervine disturbance. At least, careful inquiry could suggest no other. Whilst standing by the bedside, watching the vagaries of the patient, in a thoroughly crestfallen mood, the idea of digitalis suddenly struck me. How it was known to stimulate Setschenow's inhibitory ganglia at the upper part of the spinal cord, and, further, its sometimes happy effect when boldly administered in delirium tremens, recurred to my mind. The patient's pulse, too, was at all times high and feeble; but during hysterical paroxysms was even alarmingly so. Digitalis, therefore, being a powerful cardiac and vascular stimulant, seemed very appropriate. The result is soon told. I prescribed half an ounce of the tincture in a four-ounce bottle, with water; two tablespoonfuls (one-drachm dose of the tincture of digitalis) to be taken every hour. This was at five o'clock, and I did not see her again till between nine and ten o'clock. She was then quite calm and reasonable; a perfect contrast to her previous state. The four doses had all been taken. Previously the pulse had ranged from 120 to 130, and was very feeble in character, even at times difficult to detect. Now, on the other hand, it was steady and full, beating rather over 90 to the minute. On other occasions morphia alone had been able to break through the persistent sleep vigil; on this, however, the patient declared she felt drowsy and thought she could go to sleep. This result was happily realised, and an excellent night passed. Next morning she awoke refreshed, got up, and said she was quite well. Better still, she has remained so to the present date.

---

[1] A paper read before the first meeting of the Harrogate Medical Society, Nov. 27th, 1884.

I would remark, in conclusion, that this case seems to teach a useful lesson regarding the value of digitalis employed as an alternative to agents such as hydrate of chloral, bromide of potassium, nitrite of amyl, Calabar bean, and others so generally used as controllers of disturbed reflexes. These otherwise useful agents tend unfortunately to weaken the heart's action and lower the circulation generally. In poisonous doses they arrest the heart in diastole, whereas digitalis, similarly administered, stops the heart in systole. Digitalis also slows the cardiac beat, whilst it increases the force and efficiency of the contractions. In suitable cases, then, we would do well to remember that these most useful therapeutic powers of digitalis are united to others equally potent and valuable, which give control over reflex nervine disturbances. The result of careful experiments appears to establish that this influence over the reflex centres, as well as over the spinal cord generally, is really independent of the characteristic effects upon the heart and the blood-vessels. The latter potentiality, however, may not improbably assist the former; consequently, where long courses of the bromides and other depresso-motors are found necessary, a combination with digitalis is suggested, to avoid any weakening of the circulation liable to be produced by the former agents. In this direction the character of the pulse will be found a proper guide, for, when full and strong, digitalis will not be needed; but, when feeble and frequent, such assistance would be evidently indicated. There are, on the other hand, occasional instances where medicines commonly relied on and found most useful as sedatives to spinal irritation, have failed; and in such, as in the case I have related, digitalis may happily prove invaluable as the last arrow in the quiver of the long-suffering medical attendant.

A NOTE AND A QUESTION ON SO-CALLED SURGICAL SCARLET FEVER.

BY HERBERT W. PAGE, M.A. CANTAB., F.R.C.S.,
SURGEON TO ST. MARY'S HOSPITAL.

"OUGHT an operation to be performed on a patient whom we know to have been recently exposed to the contagium of scarlet fever?" is a question which cannot very often have presented itself to a surgeon; but it occurred to myself not long ago in the following circumstances.

On Dec. 13th, 1884, I admitted into St. Mary's Hospital a patient with suppurating glands and old sinuses in the right groin, the result of over-exertion, and perhaps general ill-health. On Dec. 13th the sinuses were freely laid open under an anæsthetic, the operation being a somewhat severe one of its kind. On the 18th the temperature rose, and a red rash appeared on the chest and abdomen. This was followed by sore-throat and general extension of the redness, and no doubt was entertained that the patient had scarlet fever. He passed through a mild course of this disease and desquamated over the whole body; but there was little or no arrest in the healing of his wound, and he was discharged from the hospital in eight weeks. He was an intelligent well-educated man, aged twenty-eight, formerly an officer in the Navy, and had been taken into the hospital for special reasons. He was quite unaware of having been exposed to recent contagion, but was sure that he had had scarlet fever twice before, the last time seven years ago.

There attended on this patient a night-nurse and a day-nurse, both lady probationers in the hospital. On Dec. 27th the night-nurse, aged thirty-five, began with scarlet fever, and passed through a typical yet very mild attack. On Jan. 7th the day-nurse, E. P. G——, aged forty-seven, called attention to the fact that her left breast had been for some time very painful and was growing rapidly in size. I was asked to see her, and learned that for the last fifteen years she had had a small painless lump in the breast, that it had begun to increase in size nine months ago, and that for the last two months its growth had been much more rapid, with a considerable amount of pain. The breast was found enormously enlarged, and to be the seat of a tumour which, both from the history and the feel, was obviously a cystic adeno-sarcoma. I advised removal as soon as possible—that; at any rate, it should not be delayed beyond a week or ten days. On the following day her friends took her to see Sir James Paget, who further advised that she should leave the hospital for a few days before operation, so as to lessen the risks of her contracting scarlet fever, to infection from which she had been continuously exposed for the last three weeks. She had never had scarlet fever before. Accordingly, she left the hospital at once, and returned on the morning of Jan. 14th, on which day I had the advantage of talking over the case with Sir James Paget, who agreed in thinking that it was right, in the circumstances of the breast disease, to operate, although the chances of the patient developing scarlet fever were very considerable. On the afternoon of Jan. 14th I removed the breast under full antiseptic precautions, Listerian carbolic spray and gauze. The wound healed by first intention; and from that moment to her discharge from the hospital, on Feb. 9th, her temperature never rose above the normal. She did not contract scarlet fever.

Such is the bare statement of the facts, and it will be acknowledged, I think, that a question of unusual difficulty was submitted to the surgeon before operation. The fortunate issue of the case gives at any rate one answer to the question, that an operation may be performed with safety on a patient who has been recently exposed to the contagium of scarlet fever. Operations have doubtless been frequently performed without ill results on persons who have been so subjected to infection, although that fact was unknown both to themselves and the operators. I question, however, if an operation other than one of real urgency ought to be undertaken knowingly in like circumstances, and I must own that for some days after the operation on E. P. G—— my anxiety was not small that she would show evidences of the fever. The necessity and urgency of the operation had to be weighed against the risks of developing scarlet fever, and had any facts been at hand to tell that the patient would certainly show symptoms of this fever after operation, that there was, in fact, no possible escape for her from such a consequence, then perhaps it would have been right to postpone the operation longer, urgent though it was. But who could say for how long? There were no such facts to guide me, and I thought it justifiable to take the chance and do the operation.

The history of these three patients clearly shows how different is the susceptibility of different individuals to the poison of scarlet fever. The man who had had scarlet fever twice before gets a third attack within four days of an operation; from him one nurse soon catches the disease, and the other nurse, who was subjected to no less risks of infection and who had not had scarlet fever before, not only does not acquire it, but even undergoes a serious operation within a week of the time when she had been nursing him. It appears, therefore, that an operation, or the state of depression induced thereby, has not that power which has been attributed to it of permitting the development of scarlet fever in a patient who has been exposed to it, unless the patient has also a certain measure of susceptibility to the disease. Nor do I know how this is to be gauged, unless it be from the age of the patient and the absence of any previous history of scarlet fever. It is improbable that anyone can have reached middle life without having been at some time exposed to the risks of infection, and in the system of every individual there must be something to determine whether poison or system shall prevail, whether the poison which has entered in shall run its course, or be deprived of its potency and cause no symptoms. That different persons and different families show all degrees of susceptibility is of course well known, and the history of these three cases seems to point to individual susceptibility as having an all-important share in allowing the development of scarlet fever after operation. How widely different, for example, must have been the susceptibility in the man and in his nurse. This conclusion seems, however, to teach that an operation ought not to be undertaken in such circumstances as have been recorded unless there be some good reason for believing that the patient's susceptibility is only small. The question which begins this paper can, as has been said, very rarely present itself to a surgeon, and I can only suggest that when it occurs very careful inquiry should be made into the history of the patient and his family, that his age be noted, and the probabilities of his exposure to contagion, and his escape from its dangers during his previous life, be fully considered. And yet his previous escape may render him more liable to an attack now, and an operation may be the one thing needful to make him fall a victim to the fever. Not necessarily so, as the case in this paper shows; but there must be a risk, and it should be fairly put before the patient and his friends. Risk unavoidable; attack by no means inevitable; hope of escape well-grounded or the reverse, according to the age and previous history. These are the considerations which must be put before them, and which must be balanced against the measure of the urgency for the operation. How difficult it may be to arrive at a right conclusion is self-evident.

In a letter to me on the issue of this case Sir James Paget writes: "I wish we could have more of these negative facts; we have nothing to weigh against the positive evidences of the bringing out of previous infection." It is with the object of recording a negative fact of much interest and importance that I venture to publish this note.

NOTES ON

A CASE OF ABDOMINAL SECTION.

By C. A. BRODRIBB, M.R.C.S.

Mrs. F——, aged forty-one, a widow with six children, was about her household work, in her usual health, on May 24th, 1884. The next day she was seized with severe pain in the abdomen, with constant vomiting. The pain seemed most severe in the right lumbar region, over the ascending colon. She said she felt that "something had given way in her inside." I was sent for in the evening of the next day (the 26th). I found her in great pain, frequently retching; pulse 108, weak; skin moist and cool. I ordered her to take fifteen minims of tincture of opium in an ounce of chloroform water every four hours, to suck ice, and to apply warm flannels over the abdomen. The next day (27th) she was much the same, but an indistinctly defined swelling over the ascending colon had appeared, extremely tender to the touch. On the 28th I asked Dr. Bagshawe to see her with me. The swelling was more defined, pain intense, but very little vomiting. Pulse 108; temperature 99·5°. No motion and no flatus had passed since the illness began. Ordered half a pint of warm oil with a quart of warm water, as an enema; twenty minims of tincture of belladonna every four hours; extract of belladonna to be applied over the tender swelling, which now had a sharply defined edge below, ending upwards indistinctly. The enema washed out a little fæces and flatus. Dr. Bagshawe thought that the ascending colon had become strangulated by adhesive bands of lymph. So matters continued for the next two days; no motion or flatus passed, and the swelling became more distinct and more tender. On May 31st the case was obviously almost hopeless if left to itself, and it was plainly unwise to wait until the patient became feverish or collapsed. Mr. Travers also kindly saw the case on the 31st with Dr. Bagshawe and myself, and we all agreed that the only chance lay in abdominal section, with a view to release the strangulated bowel. Accordingly, that afternoon, Mr. Travers chloroformed the patient, and having rinsed my hands and the sponges in a little carbolic acid and water, I made an incision in the median line, about five inches long, from just below the umbilicus downwards. I carefully stopped all the little bleeding vessels by torsion before I opened the peritoneum, which I did, of course, upon a director. I then introduced my hand, and passing it on to the ascending colon, I found it surrounded by adhesions of recent lymph, which I easily broke down with my forefinger. I also found a distinct band of lymph transversely across the bowel, and I managed to get my finger under it and broke it. I then drew the bowel sufficiently towards the incision to be able to get a glimpse of it. It was deeply congested, but sound. I afterwards squeezed onwards the contents of the swollen gut, especially one or two hard scybala, and left it soft and gurgling. I found some little difficulty in preventing the bowels from protruding *en masse* through the incision, but with a little more care I was able to close it securely with two deep silver-wire sutures through the peritoneum and four superficial sutures of silk. I dressed the wound with a little piece of lint soaked in carbolised oil, and then put over it a good-sized pad of wadding, with strapping, and six yards of wide calico bandage. I then gave half a grain of morphia under the skin, and ordered nothing but ice by the mouth. The same night the patient passed flatus per anum, but towards morning she had frequent and copious stercoraceous vomiting; temperature 97°; pulse weak. I gave drachm doses of brandy every two hours, and she rallied, and took a little of Brand's essence of beef. For the next two days she continued to improve, and passed flatus freely; lost all pain and swelling in abdomen. On June 3rd she had a large enema, which gave copious relief; wound healthy and healing well. On the 4th she had a relapse, with pain in the epigastrium and temperature 102°, which I attributed to a small slice of roll injudiciously given by a visitor. However, this attack subsided, and on the 5th (six days after the operation) the bowels acted freely of their own accord, the temperature fell to normal, and the pulse improved. On the 6th I removed the sutures, as they caused a "pricking" pain, and I found the wound all healed by first intention. I continued of course to support it with strapping and bandage. I gradually improved the diet, and on the 7th the patient sat up. She is now (seventeen days after the operation) weak, but able to go downstairs, and is practically quite well.

The points of interest to be noted in this case are: first, the rarity of the operation itself in private practice, as it is generally only resorted to as a forlorn hope; secondly, the favourable result, without any special advantages, such as hospital treatment and nursing and antiseptic precautions. The cottage in which the patient lives is one of a row of little houses in a crowded part of the town not particularly clean, airy, or well drained. The operation itself presents no particular difficulty, and requires no great skill in the operator; and this case seems to show that the dangers of abdominal section have hitherto been somewhat over-estimated; and that elaborate antiseptic treatment (which cannot well be obtained at the homes of the poor) is not necessary. Cases of intestinal obstruction are sadly common in the practice of all medical men, and are almost always fatal. I venture to hope that my professional brethren may be encouraged by this case to endeavour to save life in such cases by operation when other means seem likely to prove of no avail.

I must not omit to add that my best thanks are due to Dr. Bagshawe and to Mr. Travers for their kind advice and assistance, and also to the good ladies connected with a church in the neighbourhood who so tenderly and skilfully nursed the poor patient day and night until she was well out of danger.

Hastings.

CASE OF MYXŒDEMA IN A WOMAN AGED SEVENTY-SIX.

BY C. W. SUCKLING, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

L. L——, a woman aged seventy-six, was admitted into the workhouse infirmary on November 12th, 1884. Before I saw her the nurse of the ward told me that another case of myxœdema had been admitted, she having had one, which proved fatal, for twelve months under her charge. On hearing the patient speak I at once recognised the similarity of her mode of utterance and tone of voice to those of the other patient above mentioned, and it was in this way that the nurse detected the disease. No family history of importance could be elicited, and no history of trouble, want, or excess in any way could be obtained. She had been employed for years as a washerwoman, but lately had been too feeble to work. She complained only of coldness of the feet and weakness of the legs. She had had eight children; no miscarriages. She is a big, stout woman, with a heavy fatuous expression, the complexion is sallow with a circumscribed flush on each cheek. There is puffiness above and below each eyelid which does not pit on pressure. The nose is large and broad, and the alæ nasi thick. The lower lip is thick and protruded and somewhat cyanosed. There is hair on her upper lip and chin. The teeth are nearly all gone, the tongue and uvula large. The appetite bad. The skin is harsh, thick, dry, translucent, scaly, and wrinkled. She never perspires. Her limbs are large and there is a general œdema which does not pit on pressure, except in the legs and feet, where it does so slightly. There are thick swellings resembling fat above each clavicle. The hair is very scanty. The thyroid body cannot be felt although the rings of the trachea can be distinguished down to the sternum. The heart sounds are feeble, the pulse regular, small, feeble, and infrequent, 48 per minute, and there is certainly cardiac debility. The respiration is slow (13 per minute). She complains of a sensation of coldness in her feet, also of tingling, numbness, and formication in the hands and feet. Perceptions of pain and touch are retarded; localisation perfect. The pupils are unequal; they respond to light and accommodation. The hearing is very defective. Taste and smell normal. The reflexes are normal. She is slow in her movements, and fumbles in dressing herself; her gait is slow, with short steps. There is no agoraphobia or pain in the head. The speech is slow and drawling, and exactly resembles that of the other cases I have seen. Her intelligence appears fairly good; the memory is defective. She is slow of perception, and takes a considerable time to appreciate and answer a question. The temperature is below normal, ranging from 95° to 97° F. The urine averages forty ounces daily, contains no albumen, and its specific gravity is 1010. The percentage of urea estimated by Squibb's process is 1·15 per cent. For the last few days she has suffered from diarrhœa. She is very quiet and placid, and has had no fits or attacks of excitement.

This case is the third one of myxœdema that I have had under my care. All three have been women—two of them about the climacteric period of life. Two have proved fatal after being under observation for several months. In both of these fatal cases there were convulsions, shortly preceding death, which was by coma. In one of them delusions and attacks of temporary excitement occurred. In all the temperature was low, the urea diminished, and the heart feeble and slowly beating. In one of the fatal cases a gradual slowing of the pulse began two or three days before death, a few hours before death being 20 per minute, the patient at the time being comatose. No albumen could be detected in the urine examined shortly before death. Two of the patients were sisters. One of the patients fractured her patella; this was probably accounted for by the toneless condition of the extensor muscles of the knee, allowing the knee to give way suddenly, and the effort to recover herself fracturing the bone. I have tried jaborandi, nitro-glycerine, iron, arsenic, and baths in these cases without any appreciable benefit to the patient. The prognosis, in my experience, is of course very grave, the patient at any time being liable to a fatal coma. Dr. Oliver, in a clinical lecture on Myxœdema, called attention to a pause between inspiration and expiration as long as the sound of inspiration itself. This has not been present in the cases I have seen. West, however,[1] describes alterations in the respiratory murmurs, and says that Cheyne-Stokes' breathing has been observed in this disease. Many case of myxœdema have now been published, but I cannot find any case approaching in age this one.

ST. GEORGE'S HOSPITAL.

A CASE OF FACIAL CARBUNCLE; DEATH; NECROPSY.

(Under the care of Mr. HOLMES.)

THE following case is a good example of the more severe variety of the disease known as facial carbuncle, death occurring as in the majority of these cases, which are happily uncommon, from pyæmia. No decisive opinion has been arrived at by the profession as to the exact relationship between this disease and true carbuncle, some considering it as the same, modified by position, others considering it to be allied to phlegmonous erysipelas. It will be observed that, in the case recorded phlebitis of the facial and other veins was noticed, preceding the more marked symptoms of pyæmia. In the diagnosis of this disease it is important to remember its resemblance in some respects to malignant pustule.

For the following notes we are indebted to Mr. H. W. Allingham, late house-surgeon:—

Bessie J——, aged twenty, single. Family history: Father died of bronchitis at a good age; other members of the family are alive and healthy. She had always had bad health, being very anæmic, and suffering from amenorrhœa. For this she had been to Eastbourne, and had only returned about a week previous to her admittance into hospital. On Dec. 23rd she complained of some pain in the left side of her upper lip, and noticed it to be very red on its inner aspect. Hot fomentations were used, but the swelling increasing a doctor was consulted, who ordered a poultice to be applied. Deriving no benefit from this treatment she was brought to the hospital.

Dec. 27th.—On admission she appeared very anæmic, the temperature being 105°; pulse 140. On the left side of her face, at the angle of the mouth, involving more of the upper than the lower lip, was a large reddish-blue indurated mass, about two inches in circumference; on this were six yellow points, from which pus could be squeezed. The rest of the side of the face was swollen, being hard and brawny, with neither sense of fluctuation nor œdema; upon this were two or three small boils scattered about. This swelling extended from the eyelids, which were thickened and closed, down to the angle of the jaw, and spreading slightly down the neck. Stimulants were given and five grains of sulphate of quinine every four hours.

28th.—The lip was still of a darkish hue, and more yellow points had made their appearance, those dotted about the cheek being very pronounced. Streaks were apparent, following the course of the facial vein and its branches, which felt like cords, being evidently due to phlebitis. The eyelids were more swollen; sordes on the teeth; tongue moist, but very dirty; skin dry. The patient was slightly delirious at night and complained of intense headache. Mr. Holmes made an incision about an inch in depth along the lip at the junction of the mucous membrane and skin, but only a little venous blood (no pus) came from the wound.

---

[1] Boston Medical and Surgical Journal, vol. ii., page 80.

Temperature, morning, 104°; evening, 102°. Pulse in the morning, 140; evening, 136. Six ounces of port wine and five ounces of brandy were taken during the day, and an injection of a third of a grain of morphia was given at night.

29th.—The patient seemed much worse; the lip was bluish-black and in a sloughing condition; inflammation of the facial vein was still more marked; the eye was prominent and immovable, with a slight hæmorrhage under the conjunctiva on the outer side. The boil-like prominences about the cheek presented black sloughs on the surface. Tongue dry. Temperature, morning, 103°; night, 104°; pulse, morning, 156; evening, 140; respiration, morning, 52; evening 60. Some signs of pneumonia appeared in the left axillary line. About 6 P.M. she was delirious, having slight tremors of the right arm and leg, which continued up till 11 o'clock, when she died.

Autopsy.—The brain was soft and congested; the superior longitudinal, lateral, and cavernous sinuses, and left ophthalmic veins contained a dark, soft clot, friable, and in some places yellow and semi-purulent. A purulent disintegrated clot filled the entire length of the external and internal jugular veins. The pleuræ contained some fluid, and both visceral and parietal layers were covered with soft recent greenish lymph. The cut surfaces of the lungs were deeply congested; in the centre of the left were numerous scattered foci of suppuration, from the size of a sago-grain to a pea. The bronchi were congested and filled with frothy fluid. The liver, spleen, and kidneys were congested. There were no internal hæmorrhages or peritonitis.

RADCLIFFE INFIRMARY, OXFORD.

A CASE OF ATAXIC ARTHROPATHY: REMARKS.

(Under the care of Dr. BROOKS.)

W. C——, aged forty years, who works on a steam threshing machine, was admitted into the Radcliffe Infirmary on February 25th, 1885, with symptoms of œdema of the left leg, together with considerable effusion into the left knee-joint. He is an intelligent man and gives a clear concise account of his illness up to the present date. Two months ago he first noticed a swelling of the left knee, which gradually became larger and larger until it attained the present size. The swelling of the knee had been preceded by pains in both lower legs, which were of a gnawing character. These pains had been present at intervals for between two and three years. During the time the knee was swelling he did not suffer any pain in the joint, nor was it at all red or tender. When he bent his knee in walking he observed that there was a crackling sound produced in the joint. He noticed that his legs as he lay in bed would give occasional spasmodic jerks. Shortly after the knee began to swell he found that he could not walk steadily in the dark, but he considered that this was due to the condition of his knee-joint, which had made his leg somewhat weak. He, however, had not any difficulty in getting about during the day with the help of a stick. He had not felt any abnormal sensations in his feet, and could distinguish by means of his feet the character of the ground on which he walked. For six years he had been in the army, during which time he had not had occasion to go into hospital, although he had served three years and a half in Jamaica. He had not been subject to gastric crises. No history of syphilis could be elicited. From the nature of his work he is much exposed to the weather.

On admission the left knee and the upper two-thirds of the lower leg appeared considerably larger than the corresponding parts on the right side, the measurement over the left knee-joint exceeding that over the right knee-joint by two inches. The swelling at the joint consisted of a large quantity of fluid in the synovial membrane; the lower end of the femur and the upper end of the tibia were slightly and uniformly enlarged. The joint did not present any abnormal redness, and its temperature was the same as that of its fellow of the opposite side. The joint was quite smooth, and there were not any irregular nodules of adventitious bone. There was partial luxation of the joint inwards and backwards. There was considerable semi-solid œdema of the left leg below the knee-joint. On moving the joint loud crackling was heard, which was in fact perfectly audible to people two or three feet from the patient. The movement of the joint caused no pain whatever, even when the ends of the bones were forcibly approximated. The posterior surface of the patella when rubbed against the anterior surface of the femur felt rough. The ligaments of the joint, especially the capsular ligament, were very lax, and allowed the finger to be thrust into the joint between the ends of the bones. Lateral movement would be produced when the leg was extended. The patient could stand perfectly steady, with his feet together, and without any support, as long as his eyes were open. He walked with a firm step when allowed to spread his feet well apart from one another, so as to form a broad base for his body, and did not exhibit any incoördination that could not be accounted for by the state of the knee-joint. When he turned, he required some space to get round in, and was slow and awkward in executing the movement. When standing with his feet together and his eyes closed, coördination was distinctly less than normal, and he swayed considerably. On trying to walk along a line on the floor, his movements became markedly incoördinate. It was found that coördination was less interfered with when his boots were on than when his feet were bare. Patellar reflex was absent on both sides. Muscular power was unimpaired, and tactile sensation normal. The pupils were unequal, and did not respond to light. Accommodation could be readily performed, and was accompanied by contraction of both pupils. Sight was good both for colours and for type. By the ophthalmoscope it was seen that the discs were pale, but no distinct optic nerve atrophy was present. The control over the bladder and rectum was perfect. Since admission the œdema of the leg has become less marked, and there is slightly less synovial fluid in the joint. The crackling heard on moving the joint has gradually disappeared. The ligaments of the joint are very lax, and allow more movement than on admission. The incoördination, on standing with the eyes shut, remains as it was on admission.

Remarks by Dr. BROOKS.—The case is a good instance of ataxic arthropathy as described by Charcot.[1] The joint attacked is the one most commonly diseased in locomotor ataxia. The tumefaction of the joint first attracted the patient's attention and caused him to seek advice, but it is not possible to say how long the patellar reflexes had been absent before this. There was not any traumatic or other cause for the disorganisation of the joint. The arthropathy has occurred, as is commonly the case, between the prodromic and incoördinate periods of the disease. The presence of the Argyll-Robertson phenomenon at this stage of locomotor ataxia is in accordance with the statistics given by Gowers in his paper before the Ophthalmological Society.[2] One curious point I am at a loss to account for is the fact that coördination is more perfect when the patient has his boots on than when his feet are bare. The tumefaction of the joint, according to the patient's account, was much more slowly developed than in many of Charcot's cases.

CHILDREN'S HOSPITAL, NOTTINGHAM.

A CASE OF MENINGOCELE; OPERATION; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. LEWIS W. MARSHALL.)

C. B——, six weeks old, was admitted on January 30th, 1884, with a large tumour on the back of the neck, said to have existed at the time of birth, but on admission very much increased in size. The description given by the mother was as follows: It was about the size of an egg at birth, and hung to the scalp at the back of the head; white in colour, turning to a bluish tint. At the end of a week it was larger and red in colour. Some fluid escaped at a fortnight old. The tumour, as seen by Dr. Marshall, was as large as an orange, spherical in shape, attached by a short thick pedicle an inch long to the scalp at a point corresponding to the occipital protuberance, and hanging backwards on to the shoulders. The swelling could be lifted away from the skull, and no reduction in size was effected by pressure. It was soft, fluctuating, translucent, and resembled in appearance a spina bifida. A white broad line ran across the tumour from before backwards. There appeared to be no connexion between the posterior fontanelle (which was open) and the swelling. Pressure produced no ill effects upon the child. Its general health was good; there was no history of "fits" or squinting. The child was fed by the mother's milk, which was taken well.

Jan. 31st. — The tumour was tapped under chloroform, after securing the pedicle by an old pile clamp, with screws at either end. When the cyst was emptied of its contents (clear limpid serum) the growth was removed by the knife. The edges gaped too much for a continuous suture to be used, and three harelip pins with twisted sutures were passed through, with the double object of approximating the edges and preventing the clamp slipping off. In the centre of the cut surface a small channel was found, which admitted the end of a fine probe down to the point of compression by the clamp. The middle harelip pin was made to transfix the walls of this channel before passing out again on to the skin surface. The total quantity of fluid withdrawn was six ounces. On examination the tumour was found to be a meningocele, the membranes being collected into a rope-like body at the pedicle, with the small channel above referred to in the middle. There was no oozing of fluid or bleeding after the operation. The stump was washed over with boroglyceride.

---

[1] Diseases of the Nervous System, 2nd series, New Sydenham Society.

[2] THE LANCET, June 16th, 1883.

Feb. 1st.—Clamp removed twenty-two hours and a half after operation.

3rd.—Two lateral pins removed, but the central one left in. The child was sleeping well and taking the breast. In the afternoon the anterior fontanelle was noticed to be raised, and the child was more restless. Some puffiness, too, was observed at the back of the neck.

4th.—Child more lively. Swelling in neck less, and fontanelle less tense. Ordered bromide and iodide of potassium, one grain of the former to an eighth of the latter, three times daily. 9 P.M.: Eyes staring; vacant expression.

5th.—Some cerebro-spinal fluid oozed away. The orifice of the channel was painted over with collodion. The wound surface, which was grey and sloughing, was dressed with oil of turpentine (1 in 6).

6th.—Slight oozing of fluid.

7th.—Last pin cut out.

8th.—Medicine omitted; child brighter and better in every way; anterior fontanelle flat.

14th.—Left the hospital. The mother lived in the country, and unfortunately missed her omnibus, and the child was therefore exposed much longer than was necessary on a cold day.

18th.—The child was brought into hospital, the mother having noticed twitchings of the face and limbs the night before, and the breast was refused. 5 P.M.: Had a convulsion; medicine returned to, every three hours. The child was placed in a dark room and fed with mother's milk by a spoon.

19th.—Occasional twitchings of the face and limbs, and the head drawn backwards; bowels relieved by enema.

20th.—Mother's milk disappeared; cow's milk and water used as food. Child much better; slept well all night; medicine given less often.

21st.—Jerking of trunk backwards; eyes open. 3 P.M.: Vomited milk in curds.

24th.—Vomiting ceased. 6 P.M.: Shrill scream; return of twitchings; swallowed with difficulty; face and neck flushed; eyes fixed; anterior fontanelle very tense; head noticed to be larger. Medicine as before.

27th.—Died to-day, having slowly and steadily become worse.

Necropsy.—The wound nearly healed. On removing the scalp an opening, half an inch in length by a quarter of an inch at its broadest point, was found three-quarters of an inch behind the posterior fontanelle, communicating with the interior of the skull, but closed by membranes which were welded together into a rope and attached to the cerebellum, a portion of which was torn away on removal of the brain. On cutting through the parietal bones the left lateral ventricle of the brain was opened, and a large quantity of fluid escaped. The surface of the brain was coated with lymph, and showed everywhere evidences of recent inflammation. Both lateral ventricles were very much distended, the left markedly so. The fluid in the left ventricle was clear, that on the right side was opaque and milky. The third and fourth ventricles were distended with fluid, and their boundaries softened and disorganised.

Remarks.—In this case there appeared to be legitimate grounds for adopting, with a fair prospect of success, the measures suggested by Mr. Holmes in his Surgical Diseases of Children, although these means had not, at the time his work was written, been put to the test by him. From the symptoms there was no evidence of existing internal hydrocephalus; but this condition is stated to be usually present to a greater or less degree in all cases. There was clear evidence of the absence of brain matter, and that the channel of communication with the inside of the skull, if one existed, was small. The child's general health was also exceptionally good. A tubercular history was made out on the father's side, yet not pronounced. In any future case with the same favourable prospect, the operation as done here might again be attempted with a different result.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Excision of Cerebral Tumour.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President in the chair. Great interest was manifested in the proceedings, though there were but few who joined in the discussion.

Dr. HUGHES BENNETT read a paper on a case of Cerebral Tumour, the surgical treatment of which was managed by Mr. Rickman J. Godlee. The chief features of interest in this case were, that during life the existence of a tumour in the brain was diagnosed, its situation localised, and its size and shape approximated entirely by the signs and symptoms exhibited, without any manifestations of the growth on the external surface. This growth was removed by a surgical operation without any immediate injurious results on the intelligence or general condition of the patient, who lived relieved of his former symptoms for four weeks, and who at the expiration of that time died, not from any special failure of the nervous centres, but from the effects of a secondary surgical complication. The case, however, taught important physiological and clinical lessons, and suggested practical reflections which might prove useful to future medicine and surgery. In the communication the history and condition of the patient on examination were detailed. The diagnosis arrived at was stated with the reasons for the same. The surgical operation and subsequent treatment were described with comments thereon. The progress of the case, its termination, and the post-mortem reports were recorded. Finally a commentary was added in which all the important clinical, physiological, and pathological points of interest were discussed. (For further particulars of this case, *vide* THE LANCET, 1884, vol. ii., p. 1090, and p. 23 of the current volume.

Dr. HUGHLINGS JACKSON congratulated Dr. Hughes Bennett on the accuracy of his diagnosis. The operation Mr. Godlee performed showed that Dr. Bennett was right in saying that a cerebral tumour might, so far as the operation itself goes, be safely removed. The patient, most unfortunately, died, but he died of a secondary surgical complication. Dr. Hughlings Jackson also warmly congratulated Dr. Ferrier from whose valuable researches the tumour was localised. Speaking more generally of localisation of cerebral tumours with regard to trephining, Dr. Hughlings Jackson said that there was a kind of monoplegia, often passing into hemiplegia, which was almost certain evidence of cerebral tumour; a paralysis beginning very locally, for example, in the thumb and finger and spreading very slowly week by week. In such a case he should not advise trephining, since there would be great probability of a large tumour in the centrum ovale, not certainly, for he had seen such hemiplegia in a case of tumour of the dura mater pressing down on the cortex. The convulsive seizures of localising value were not cases of epilepsy proper, but epileptiform seizures, convulsions beginning one-sidedly and only locally in the hand, cheek, or foot. Whilst these seizures pointed with certainty to disease of the opposite cerebral hemisphere, they did not always occur from such gross disease as tumour. In some there was local softening. When, however, there was also double optic neuritis, such gross disease as tumour might be confidently predicted. Even yet there is not evidence of exact position. Dr. Hughlings Jackson had not yet seen a case of epileptiform seizure caused by disease outside Ferrier's motor region. But such cases were recorded by great authorities, so that, repeating in effect what Charcot and Pitres had urged, we required also some local persisting paralysis of the part convulsed—persisting, since temporary paralysis after a seizure was no further help towards localisation. So far, then, three things were required: local persisting paralysis, epileptiform convulsion, and double optic neuritis.

Dr. Hughlings Jackson mentioned the case of a man who had had convulsion and paralysis of one arm; a tumour, a cubic inch in bulk, was found involving the hindermost part of the uppermost frontal convolution. This was before Hitzig and Ferrier's researches; the exact position was not diagnosed. That tumour might probably have been got out with safety, yet there was considerable softening; moreover, there was a tumour in each lateral lobe of the cerebellum, although there had been no cerebellar symptoms. Another case in which a woman had very many convulsive attacks of one arm (later wider seizure was mentioned). In this case Dr. Hughlings Jackson correctly predicted tumour of the hindermost part of the uppermost frontal convolution and adjacent ascending frontal convolutions, but not with the confidence he should have done had Ferrier's researches then been made. The tumour was about an inch in diameter, and, had it been removed, very likely the woman's life would have been saved. She had not double optic neuritis, but, making an exception to a former statement, were he to observe a case of repeated convulsions nearly always limited to one arm, exactly alike at each recurrence, he should, even without double optic neuritis, consider them to be due in all probability to a tumour in the region mentioned. In another case he had diagnosed correctly tumour of the same region, but there were also other tumours in that half of the brain. Admitting difficulties—that the tumour might be very large; that there might be softening about it; that, besides the tumour localised, there might be others,—yet in a case where the tumour was evidently going to kill the patient, when there was intense pain, and when, as sometimes happened, the patient had twenty or thirty fits daily, the patient would consent to risk something, and a surgeon might justifiably operate. Dr. Hughlings Jackson remarked that, after operation in such cases as he had mentioned, there would, he thought, be the serious drawback of some permanent paralysis; but this was little in comparison with the misery of pain, torment, repeated fits, and great danger of death. In conclusion, he said that in a case of convulsion limited to one arm, or beginning in one leg, with some persisting local paralysis and double optic neuritis, he should diagnose tumour or other such gross disease of the upper part of the Rolandic region, and should seek surgical advice as to the propriety of trephining, not forgetting to state prominently the three difficulties mentioned.

Dr. Ferrier congratulated the authors on their success, which was gratifying both to Dr. H. Jackson and to himself. He had watched the case with the greatest interest, and was present at the operation, which was entirely successful; although the patient had been under the influence of the anæsthetic for two hours, yet at the end of that time he became conscious and was able to answer by gesture simple questions put to him by Dr. Ferrier. So that the patient bore the operation without any great shock to the nervous system, and he might say without danger to life, for there could be no doubt that death was due to an inflammatory complication, such as could only come under the chapter of accidents. The operation, if performed strictly antiseptically, need not be attended with any risk of encephalitis. Some authors had said that operations on the brain of monkeys were free from risk of encephalitis, but this was not the case. Monkeys were quite as difficult of surgical management as human beings. If antiseptics be employed inflammation need not result. In his earlier series of experiments on monkeys antiseptics had not been used, and then every animal suffered from encephalitis. During the experiments made with Professor Gerald Yeo, in which both frontal lobes or both occipital lobes, or other parts of the brain, were removed, this was done without any inflammation resulting because antiseptics were employed. He made reference to a case which had been under his care at King's College Hospital, because it illustrated important principles. The patient was a man who for two years had suffered from cerebral symptoms. He was admitted with coma and left-sided paralysis, and suffered from pain in the right frontal region when the coma lessened, as it did at times. The right eyeball was feebler than the left, and he had all the symptoms of cerebral tumour. At his instigation an exploratory operation was carried out by Sir Joseph Lister. The skull was trephined at the right frontal eminence. The frontal lobe of the brain was found to be distended by what at first was thought to be a cyst, but turned out to be the distended lateral ventricle. The knife, passed downwards, led to the escape of a gush of fluid; nothing further was done. The paralysis was relieved and the coma diminished by this procedure, but the patient died eight days later. At the autopsy a new growth was found to spring from the sphenoidal fissure, and had pressed upon the corpus striatum, and so caused the paralysis; the bulging of the eyeball was due to this new growth. This tumour would have been doubtfully removable, even supposing that it had been detected by the exploratory operation; but in order to verify a diagnosis exploratory measures should be adopted, for the disease if left alone would prove fatal. He felt confident that the future would yield more favourable results.

Dr. Macewen contributed an account of some cases which had been under his care, and which are being published separately in our columns.

Dr. H. Bennett referred to the important cases of Dr. Macewen, which had been attended with such brilliant success; yet he considered that his cases were scarcely analogous with the one brought forward; for a limited lesion of the brain had been diagnosed entirely by symptoms, whereas in Dr. Macewen's first case there were other indications to guide the surgeon. Then there was paralysis of a more extensive character than obtained in his (Dr. Bennett's) case. He then exhibited to the Society a brain taken from a patient who had been under the care of Mr. Davy. This patient had been trephined, and from the substance of the cortex as many as eight pieces of bone were removed; the bone had been forced there by an accident. The operation left behind it a large hole in the brain, which would take a pigeon's egg. There were no antiseptics used in this case, and yet the boy made an uninterrupted recovery. Death ensued some time later from acute double pleuro-pneumonia. The autopsy showed no trace of injury to the brain, except a hard dense cicatrix, the site of the former operation.

Mr. V. Horsley said that in this last case, which had been done without antiseptics, the conditions were hardly parallel with those which obtained in cases in which the brain had sustained no previous injury. In this case of depressed fracture, no doubt adhesions would be produced all round the injury, and effectually shut off the wound from the rest of the cavity of the arachnoid. Some practical surgical points in experiments and operations on the brain were alluded to. There was no doubt that morphia diminished the tendency to hæmorrhage, and the vigorous welling up of blood from numerous arterioles was seen to a less extent in his and Schäfer's experiments. The morphia was hypodermically injected, about two-thirds of a grain being the dose employed. As to the kind of dressing, he preferred the dry permanent dressing, for he had been astonished to see how rapidly the effused serum was absorbed. In only five out of forty experiments had he aspirated with a view to diminish the tension of the effused serum.

Mr. Godlee congratulated Dr. Macewen on his successful and brilliant results. He ventured to think that there was not so much hæmorrhage in opening into an abscess cavity as in cutting the unaltered brain. Moreover, he had employed the actual cautery partly no doubt to arrest hæmorrhage, but also with a view of destroying the deeper parts of the tumour, the boundaries of which were indefinite in the downward direction. In his opinion the inflammatory action was the cause of the hernia cerebri; inflammation would probably not occur without some putrefaction having been set up. In removing the deep part of the growth, which appeared to extend downwards in a conical fashion, he had used a Volkmann's sharp spoon, but some instrument rather larger and blunter like a salt spoon would probably have answered the purpose better. Large wounds in man had not in his experience been well treated when the wound was completely closed, and he considered that wounds in lower animals were not perfectly analogous to wounds in man. So that he agreed with Dr. Macewen that a drainage-tube should be used; otherwise there would be no opportunity for an extensive effusion of serum and blood to make its way out. As to the cause of the disaster in his case, he had no doubt that it was due to putrefaction, which was probably the result of imperfect purification of the scalp. He remembered that blisters had been employed in the occipital region, and had not healed; the serum from these sores might have contaminated the wound. At another time he should have the head shaved all over and thoroughly washed first with soap, and then with corrosive sublimate, and finally soaked in a strong solution of carbolic acid.

CLINICAL SOCIETY OF LONDON.

Obstruction of Arteries and Veins extending over many years.—Osteitis Deformans.—Hæmoptysis treated by Artificial Pneumothorax.—Removal of Calculus from Vermiform Appendix.

AN ordinary meeting of this Society was held on May 8th, Mr. Arthur E. Durham, F.R.C.S., Vice President, in the chair.

Dr. B. HADDEN read notes of a case of Obstruction of Arteries and Veins extending over many years. The patient was a healthy-looking man, aged fifty-one. His paternal grandparents had gout. The patient denied syphilis, but there were strong grounds for suspecting past infection. His present disease began suddenly in 1868, when he was seized with a sharp pain in the left foot, said to be gout. Phlebitis of the same leg, with swelling and tenderness of the limb, followed, the attacks lasting five months. In 1880 he came under the care of Dr. Mitchell Bruce for sudden obstruction of the right brachial artery. The radial artery was small, and the heart was irregular. Very soon the radial and ulnar veins became painful and thrombosed. In 1881 he had sudden loss of power in the left arm, but not in the leg. The face was thought to be drawn. There was some mental confusion, but no actual loss of consciousness at the time of the attack. Between 1881 and 1884 he is said to have had several attacks of arteritis and phlebitis. He was admitted into St. Thomas's Hospital under the care of Dr. Stone on Feb. 2nd, 1885. He had pain and tenderness in the right groin, with feeble pulsation of the femoral artery. No beat could be felt in the posterior tibial, but the dorsalis pedis was pulsating strongly. The right internal saphena vein was thickened and thrombosed. There was slight œdema of the foot, and some enlargement of the superficial veins. Pulsation was absent in the right brachial and feeble in the radial. There was a large collateral branch strongly pulsating just above and behind the external condyle of the humerus. There was no enlargement of the superficial veins. There was slight varicosity of the veins of the left leg, but otherwise the vessels were unaffected, as were also those of the left upper limb. On the front of both legs there were pigmented scars, very suggestive of syphilitic disease. The heart was irregular, but there was no bruit and no hypertrophy. The urine was free from albumen. The pain in the right groin persisted for six weeks, without any fresh obstruction occurring. He had two attacks of severe headache localised in the right frontal and parietal regions, but they both passed off without further mischief. The treatment consisted of mercury and iodide of potassium, with hot *soda* baths and complete rest. He is now free from pain, and is better than he has been for two years. In discussing the case, the author believed there was no evidence that the affection was gout. Possibly it was syphilitic. Two explanations may be offered with regard to the pathological nature of the disease. First, there may be embolism affecting the arteries, and phlebitis; secondly, there may be an inflammatory condition affecting the coats of both arteries and veins. The latter hypothesis seems the most probable, and it is supported by the fact that, although there was great tenderness in the right femoral vessels for six weeks, no fresh obstruction occurred.—Mr. A. P. GOULD referred to the cases (which Dr. Hadden and he had shown during the last session) of obliterative arteritis from which the present case differed very materially, for there was no evidence of affection of the veins. A case which occurred in Billroth's practice had been reported by Dr. von Winiwarter, who had written by far the best account of the disease. In Billroth's case the plantar and digital vessels were first affected, the posterior tibial being involved later, and its companion veins were affected. In the wide extent of the vessels affected, Dr. Hadden's case was peculiar; the disease was limited to one upper extremity in the cases shown last session. As a rule, the progress of the affection was steady and chronic, and attended with pain and some gangrene; the final result was generally a shrunken and colder limb. In Billroth's case the disease lasted a few years, and, although it was not very extensive, it recurred in the foot. In Dr. Hadden's case the obstruction appeared to be more sudden and acute than in the majority of cases of obliterative arteritis. He asked whether the pain was very severe; if it were limited to the vessels or spread over the whole limb; whether the obstruction spread from the smaller arteries up to the larger or in the opposite direction; also, whether the vessels were first felt to be harder and firmer than normal with lessened pulsation and only later on became completely pulseless; with regard to temperature, also, was it raised? as happened in his case; was there much swelling? there was very little of the hand and forearm in his case. Did the patient suffer very much from coldness?—Dr. ANGEL MONEY considered that the interesting case was worthy of inquiry from a neurological point of view. Lewaschew had experimentally shown that chronic irritation of nerves led to inflammatory changes in the walls of arteries. With this view in mind he asked whether there were any symptoms pointing to disease of the nerves.—Dr. HADDEN said that the pain was very severe but limited to the vessels; the disease spread from the large to the small vessels; the temperature was usually normal, but rose somewhat when the localised headaches appeared. There was no marked swelling of the limbs, but a great deal of coldness was complained of by the patient. The man was highly emotional, but he had not suspected a nervous causation for the disease.

Mr. J. R. LUNN read notes of a case of Osteitis Deformans. In St. Thomas's Hospital Reports for 1883, vol. xiii., he had given a full account of a case of osteitis deformans. Since 1876, when Sir James Paget drew attention to the disease, numerous other cases have been recorded. The chief symptoms noticed by the patient are pains of a rheumatic character in the affected limb, loss of height, and in male patients increased size of the head, rendering their hats too small. In a fatal case the morbid process was nearly universal, but the chief stress seems to have fallen upon the bones about the main axis of the body. The absorption and disappearance of the original bone seems to have been the primary event in the course of the disease, and must have taken place, not by a coarse process, but by a very delicate interstitial change. As to the nature of the morbid process which produced the anatomical alteration, the view advanced by Sir James Paget that it is a kind of chronic ostitis has been generally accepted. But, while fully admitting that chronic inflammation may have some share in the process, he did not think that it altogether accounts for the changes found. The conclusion he had come to is that osteitis deformans consists of:—1. A constitutional disease producing atrophy and absorption of a large part of the osseous system. 2. Consequent weakening of the bones, so that they yield when exposed to strain. 3. Compensatory strengthening of the growth of what may be looked upon as a variety of callus. 4. The occasional formation of definite tumours. 5. Fatal cachexia.—Mr. MACNAMARA said that in these cases there were pains of a rheumatic character. He had recently made some observations on the insertion of tendons into bone, and he had found that the tendons were prolonged into the bones; possibly the perforating fibres of Sharpey were such prolongations. The tendons were really portions of bone on this view, and he surmised that the disease might have commenced in the tendons and spread into the substance of the bone.—Dr. F. L. BENHAM spoke of the helplessness of the patients and of their weakness, which might be accounted for by the atrophy of the bones; for the new bone thrown out was obviously a secondary change. He thought there was merely a difference of degree between this disease and osteomalacia.—Dr. THOROWGOOD remarked on the failure of anti-rheumatic remedies to relieve the symptoms of this disease. The administration of small doses of Fowler's solution was followed by marked improvement in his hands. It would be interesting to know the very earliest symptoms of the disease. He had seen cases in which pain in the joint with crackling sensation in passive movement were the main features. Did these cases go on to osteitis deformans?—Mr. WARRINGTON HAWARD referred to the possible occurrence of the disease without any rheumatic pains. In cases that he had seen pain was not a marked symptom; not unfrequently the urine was alkaline and there were no other signs of rheumatism.—Mr. STEPHEN PAGET could not concur in the remarks of Mr. Macnamara, for the chief deformity of the bones occurred in parts away from the insertion of tendons, the skull was enormously thickened in the region of the eminences, and there was bowing and thickening of the anterior surface of the tibia in cases which he had seen. The curves of the arms, clavicles, and spine were influenced by the posture which the patient assumed. Much difficulty of respiration was brought about by ankylosis of the ribs.

Patients die partly from cardiac weakness and partly from the difficulty of breathing. Full mental activity seemed to be retained, and there was no more loss of flesh or vigour than was natural to people of their age.—Mr. J. R. LUNN, in reply, said all his cases had had rheumatic pains. He had submitted the occipital bone and the tumour of the iliac bone to Dr. Sharkey, for histological examination. There was much irregularity in the anatominal structure of the bone; absorption or rarefying osteitis appeared to be the dominant process; the bone corpuscles were not arranged in parallel lines; there was also clear evidence of a formative osteitis. The tumour was cartilaginous throughout, and not sarcomatous. No definite history of the early symptoms of the disease was to be ascertained in the majority of cases. He believed that there was no specific cachexia in the affection.

Dr. CAYLEY read notes of a case of Hæmoptysis treated by the Induction of Pneumothorax so as to Collapse the Lung. The patient, aged twenty-one, a porter, was admitted into the Middlesex Hospital on Feb. 9th. For some time past he had suffered from a slight cough, but otherwise his health was very good. On Feb. 7th he was at work as usual. In the evening he had a sudden attack of hæmoptysis, which recurred the next morning, and again the following night; and immediately after his admission he brought up 4 oz. of florid blood. He considered that he had in all brought up about a pint. Patient was rather pale, but well nourished and of good muscular development. The left side of the chest was flattened in front, and the expansion was much diminished. There was dulness on percussion over the scapular region, and here there was feeble bronchial breathing. The breath sounds all over this lung were very faint, and accompanied by moist râles. These signs were attributed to the lung being clogged with blood. On the right side the physical signs were normal. He was quite free from any feelings of malaise, and his appetite and digestion were good. He had in all brought up upwards of a gallon of florid liquid blood, besides a large quantity of blood-stained sputum. The physical signs over the left front were much as on admission. On the right side rather fine moist râles were now audible in front and in the axillary region. The temperature was usually normal or subnormal in the morning, and varied from 101° to 101·8° at night. The breathing was but little accelerated and tranquil. As it was now evident that much repetition of the hæmorrhage, in all probability due to a pulmonary aneurysm or to the ulceration of a large vessel, must prove fatal, it was determined to induce pneumothorax, with the expectation that the great diminution of the circulation through the collapsed lung, together with the pressure exercised by the air, would arrest the hæmorrhage; and supposing there was active development of tubercle in progress in the lung, this would probably for a time be checked. It was considered that the extreme anæmia of the patient would diminish the embarrassment to the breathing likely to be caused by collapsing one lung. Accordingly, at 6 P.M. on March 10th, Mr. Hulke made an incision in the sixth intercostal space, an inch behind the anterior fold of the axilla, and intoduced into the pleural cavity a double tube, made by uniting together by a shield two pieces of elastic catheter about three inches long. The opening was protected by a small cage, lined with carbolic gauze, and the whole covered by a carbolised gauze bandage. The air passed freely in and out at the time of the operation, and the apex of the heart moved to the mid-sternal region; the respiration became much accelerated. On March 12th it was observed that the breath sounds over the left front had become more audible, and the percussion resonance less tympanitic than after the operation, and the tube was found to be completely blocked; it was accordingly removed, and a silver tube resembling a flattened tracheotomy tube was introduced in its place. The air now passed in and out freely, the resonance became tympanitic, and the "bell sound" could be elicited. The apex of the heart could be felt beyond the right border of the sternum. He afterwards complained of severe pain in the side. The temperature rose to 104·6°, and much serous fluid began to flow through the tube. The following day the tube was removed. On March 14th, though extremely prostrate, he felt better. He continued to spit frothy glairy mucus with pellets of altered blood, but there was no return of the hæmorrhage. On March 15th he was in much the same state. At 2 P.M. he died quite suddenly, apparently from syncope. After death both lungs were found studded with recent grey miliary granules. The right lung was free from any old tubercular disease. In the apex of the lung was a very small old vomica with smooth walls, and some puckering round it. The lower lobe and the lower part of the upper lobe were collapsed, and the pleural surfaces smeared with recent lymph. The pleural sac contained about two drachms of non-purulent fluid. In the lower part of the upper lobe close to the interlobular septum, which was bulged downwards by it, was a cavity the size of a walnut, filled, except at its centre, by a light-coloured laminated clot, so as to closely resemble an aneurysm. In the centre of this clot was a small round cavity containing a little loose black coagulum, and this cavity communicated with a considerable branch of the pulmonary artery. A large bronchial tube opened into the periphery of the pulmonary cavity, but was shut off by the laminated clot from the central space. At the upper part this clot was softer and more recent than elsewhere, and had no doubt recently allowed a communication to take place. The cavity in the lung containing the clot was smooth-walled, but showed no signs of any aneurysmal sac. There was no old tubercular disease around it. As the case turned out to be one of acute miliary tuberculosis, it is evident that no treatment could have availed to prevent a fatal termination. The patient did not live long enough to warrant positive conclusions as to the effect of the operation in arresting the hæmorrhage. He had two slight attacks in the following night, but there was no subsequent recurrence. The necropsy showed that the communication between the false aneurysm and the bronchus was closed, and possibly if the patient had lived complete solidification of the aneurysm would have been effected. Considering how largely the pulmonary circulation is influenced by the respiratory process, and the small amount of blood which flows through a collapsed lung, such a mode of procedure affords a means of arresting an otherwise uncontrollable pulmonary hæmorrhage. Any extensive consolidation of the lung would no doubt, by preventing collapse, be a contra-indication, and would thus restrict the applicability of the operation to a few cases. The probability of exciting pleurisy was, of course, another objection. In this case, notwithstanding careful antiseptic precautions, pleurisy was set up, but it was of a simple non-suppurative form, and but for the tuberculosis would not have added much to the patient's danger.—Dr. THEODORE WILLIAMS thought the case was one of great interest, and he congratulated Dr. Cayley on his courage. Then, as to the utility of the mode of treatment, he considered there were grounds for discussion. In many cases the patients were reduced to the last extremity by hæmoptysis, and yet finally recovered. Derivative treatment was sometimes beneficial. In a case which he had under his care where the hæmoptysis probably proceeded from a vomica, into this vomica he had injected a solution of tannic acid, with the result that the hæmoptysis almost immediately ceased. The sputa later on gave the reactions of tannic acid. What were the advantages to be gained by inducing a pneumothorax which the patient would necessarily carry with him ever afterwards?—Dr. DUFFIN said that the question to be decided was whether the immediate effect was beneficial; the lung was practically reduced to a fœtal condition through which but little blood flowed. He did not think that we need be afraid of the admission of air into the pleura. Physiologically we should expect valuable results to follow the operation. The difficulty was to know when we should be justified in resorting to this heroic remedy.—Mr. R. W. PARKER thought the treatment was rational, but there were ways of causing pneumothorax without running risk from septic agencies. He recommended the injection of filtered and carbolised air into the pleura such as he had advised in the treatment of certain kinds of empyema. A hypodermic syringe with an elastic ball and some carbolised cotton-wool were the only articles required for the operation.—Dr. S. COUPLAND did not suppose that Dr. Cayley would have performed the operation if he had known the precise pathological condition which existed in this case, which was of a remarkably singular character, for there were very few physical signs of pulmonary tuberculosis. The case proved that a large amount of disease of the vessels could occur without any physical signs of disease.—Dr. CHAPMAN thought the case would have been still more interesting if the details of treatment were given. Was the side of the chest compressed and strapped by plaster?—Mr. CHARTERS SYMONDS spoke of the induction of artificial pneumothorax as having been suggested by Dr. Mahomed in a case on which they had held a consultation. The aim of the operation was to be the arrest of phthisis.—Dr. EWART considered that an important departure in the treatment of pulmonary cavities might date from Dr. Cayley's recommendation. The arrest of the circulation in the lung might throw the other lung into such a condition as to lead to hæmoptysis from it. He remembered that some time ago Dr. Douglas Powell had induced artificial pneumothorax for the treatment of a large cavity. The upper lobe of the lung had been almost entirely destroyed, and the cavity in it had been practically obliterated, as the autopsy showed. The lower lobe of the lung was practically carnified; there was an empyema, and aseptic air was introduced as a means of treating the empyema, and at the same time with a view of causing collapse of the pulmonary cavity.—Dr. HADDEN said that the pleura might have been universally adherent, and artificial pneumothorax would be useless if the aneurysm were at the apex of the lung, as this portion would not collapse.—Dr. CAYLEY, in reply, said that every means for arresting the hæmorrhage were tried. There were no physical signs of old pulmonary disease. He thought that the pressure of air and stoppage of the circulation would have an influence on an aneurysm, even though this was in the apex of the lung. The condition of pneumothorax was not necessarily a serious matter. A patient, the subject of a wasting disease, required less area for breathing purposes than a man in sound health.

Mr. CHARTERS SYMONDS read a paper on a case in which, at the suggestion of the late Dr. Mahomed, he had removed a Calculus from the Vermiform Appendix for the relief of Recurrent Typhlitis. The following are the chief particulars of the case:—Charles S——, aged twenty-three, a basket maker, was admitted into Philip ward, Guy's Hospital, under the care of Dr. Mahomed, July 16th, 1883. The patient had typhoid fever a year ago. The report of Mr. Vernon, the clinical clerk, says that "six months ago (January, 1883) he was seized during the night with pain in the right iliac region; this increased in severity and he became ill generally, and at the end of a week was unconscious, remaining in this state four days. The illness lasted seven weeks. During the first week he vomited everything, and his bowels were not opened for ten days. During the whole time there was great tenderness in the right iliac fossa. On getting about, he noticed a hard lump in the right groin about the size of a walnut; sometimes this swelling was painless, at other times it was very tender. Since this illness he has had repeated attacks of pain in the right iliac fossa, which come on suddenly and last one or two days. The pain is relieved by poultices. At first these attacks recurred about once a month, but during the last five weeks he has had six attacks, and they have been increasing in severity." On admission there was to be felt in the right groin on deep palpation a small hard lump about three-quarters of an inch by two inches running parallel with Poupart's ligament. There was slight tenderness on pressure. The man was placed on a fluid diet, and was soon relieved of all his pain. Dr. Mahomed considered fully the question of operation, and proposed that the cæcal region should be approached by an incision in the right iliac region, as he was strongly of opinion that there existed an abscess cavity containing probably a calculus or concretion, and that the periodical occlusion of a communication with the cæcum determined the recurrence of pain. One of the attacks had been observed in the hospital, and was accompanied by an increase of the swelling, which also remained dull on percussion. Mr. Symonds thought a peritoneal adhesion constricting the last portion of the ileum might explain the periodic attacks, as he had seen a somewhat similar condition before. As the complaint continually recurred, it was decided to explore the right iliac fossa. Dr. Mahomed planned the operation, and it was on his recommendation that the incision adopted was selected. The lump was oval in shape, could be distinctly felt, but could not be taken hold of. It was well defined and only slightly tender. The most probable explanation seemed that this lump was a concretion; but whether inside the appendix, or resting in a cavity bounded by peritoneal adhesions and bowel, was doubtful. It was therefore decided to cut down upon the lump to remove a calculus present or drain a cavity should pus be found. Chloroform was administered, and under the carbolic spray an incision was made commencing two inches above and one inch internal to the anterior superior iliac spine, and curving downwards and forwards for about four inches, being much the same as that used in ligature of the external iliac, and so arranged that its centre corresponded with the position of the lump. The various structures were divided, but the transverse fascia was not distinctly recognised, owing possibly to the incision being rather near the iliac spine. The structures in front were now raised out of the iliac fossa, when the swelling could be plainly felt from behind, and as yet the peritoneal cavity had not been opened. A hand pressed duly from the front steadied the swelling, and brought it more into the wound. A vertical incision was now made over the hard lump, and a small calculus exposed. Before removing it a fine silk suture was passed through the tissues just above, so that the orifice might not be lost. The opening was then enlarged, and the calculus exhibited removed. The soft and purple mucous membrane of the appendix was seen, and its tortuous course from the aperture could be traced upwards towards the cæcum, so that there seemed no doubt of the canal having been opened. Exploration of the cavity with a probe failed to detect a channel leading towards the cæcum. No pus or other fluid was found round the calculus, nor was there any fæcal or unpleasant odour. The opening into the appendix was closed by Lembert's method, and the wound by deep silk sutures. The peritoneum was not opened so far as could be determined, and this was attributed to the adhesions that had probably taken place at the time of the first attack, and to the method adopted in reaching the appendix. The usual gauze dressings were used. The calculus was oval in shape, smooth on the surface, and measured three-quarters of an inch long, and rather more than half an inch wide. On section it showed a laminated calcareous capsule enclosing hardened fæcal matter.—With the exception of some local disturbance about the wound the patient did well, and was discharged at his own request six weeks after the operation. There remained some induration to be felt on deep pressure, but the wound had apparently healed. During the whole of his stay the temperature never rose above 99·4°. Fearing some further trouble might arise while any lump remained in the iliac fossa, he was directed to return at the first sign of a recurrence of his former symptoms. The man resumed work in a fortnight, and suffered no inconvenience till a month later, when he felt pain in the right iliac fossa, which gradually spread over his abdomen, and became so acute that he was obliged to take to his bed. Two days afterwards he observed a yellowish fluid escaping from the wound. He was readmitted two days later. There was a sinus three inches long discharging a thin yellowish fluid, and the hard swelling noticed when he was discharged. He had improved, and there was to be noted induration beneath the scar, and from here the appendix could be traced upwards. The rounded swelling that had been observed, and which varied in size, had now entirely disappeared. Three weeks after admission he was discharged, the sinus having closed, and the man being in good health. When last heard of (April, 1885), though an inmate in the Barming Heath Lunatic Asylum, he was free from his old disease, and had never had any trouble since Nov. 1883. Mr. Symonds remarked that this is the first case in which a concretion or calculus has been removed from the appendix vermiformis without at the same time the opening of an abscess, and the credit of whatever value rests in the procedure must be given to his lamented colleague, Dr. Mahomed, at whose suggestion the operation was undertaken, and who further advised the inguinal incision in opposition to that in the linea semilunaris proposed by himself. That the operation in this case was justified few will deny when it is remembered how frequently a concretion is found to be the cause of fatal typhlitis. This fæcal concretion was present in eleven out of seventeen fatal cases, in all of which the disease originated in the appendix, either as a sloughing ulcer with a concretion or a sloughing ulcer without a concretion. He mentioned this to exclude tubercular ulcers. This case was so isolated that it was not expedient to attempt to formulate conditions under which we should undertake similar operations. In none of the eleven cases mentioned above was the concretion calcareous. He directed the dissection to the posterior surface of the cæcum and appendix, not because he imagined that under normal circumstances he might avoid the peritoneum, but because here, if anywhere, he would probably meet with adhesions, and so possibly enter a case containing the appendix and concretion shut off from the general peritoneal cavity. After the study of twenty-three fatal cases, and with a knowledge of how frequently large iliac swellings due to typhlitis disappear, he suggested that some cases at least might be saved by early incision. Such cases are recorded, and success has followed the treatment.

The following living specimens were shown:—Mr. John Hopkins: Two cases of Myxœdema. Mr. Willett: A case of Congenital Enchondromata.

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the ordinary meeting held on April 10th, Dr. S. C. Smith, Vice-president, in the chair,

Dr. JACOB showed Microscopical and other Preparations from the Intestine and Liver of a case of Tuberculosis occurring in a child aged two years, which had caused death with symptoms of acute intestinal obstruction. The glands were enlarged into great masses completely surrounding and obstructing both the cæcum and one part of the ileum for about two inches. The liver showed microscopically great fatty infiltration and increase of connective tissue. The viscera from this case, freshly removed, were shown to the Society by Mr. Hartley at a previous meeting.

Dr. JACOB also read a paper on "Second Attacks of Scarlet Fever."

Mr. J. J. PICKLES related the case of one mother in three successive pregnancies giving birth to children the subject of Harelip, there being no hereditary tendency or other apparent cause of the deformity.

Professor JESSOP showed a young man with perfect movement of the elbow, on whom he had operated for Ununited Fracture of the Olecranon, by wiring together the fragments. The operation had been done some months previously, up to which time the patient had a useless and weak limb.

Professor JESSOP also showed a man on whom he had operated for Fæcal Fistula, the opening being high up in the jejunum, as shown by the motions being liquid and full of bile. The patient had been stabbed in the abdomen several years before, and had ever since had the fistula, for which he had been several times unsuccessfully operated on. The operation consisted in opening the abdomen, detaching the bowel from the abdominal wall, refreshing the edges of the opening in the gut, which was the size of a shilling and opposite the mesenteric attachment; carefully suturing the edges of the intestine by eleven carbolised silk sutures passed from within and one from without, through all the coats of the bowel; returning the closed viscus and stitching up the abdominal opening as in ovariotomy. Flatus passed after a few hours, and after the second day the temperature continued normal, the man recovering without a bad symptom.—Mr. WHEELHOUSE said that he looked on the case with great satisfaction, since on this very man he had several years ago done every operation he could think of without any benefit. He had not, however, seen the case until some time after the accident, when the fistula was fully established.

Dr. OLIVER read a paper, with demonstrations, entitled "A Contribution to the Clinical Study of the Liver, viewed through the Urine," which, together with a second paper read on May 1st, is in course of publication in our columns.

At the ordinary meeting held on May 1st, Dr. Bell, President, in the chair,

Mr. E. ATKINSON showed a patient, aged twenty-one, who had suffered Compound Dislocation of the Astragalus forwards and outwards in November, 1884. As there was a wound of four inches, the diagnosis was easily made and the astragalus was felt to be firmly fixed to the os calcis. Reduction was effected under ether without division of the tendo Achillis. When the patient was shown to the Society the ankle was somewhat swollen and stiff, but the wound was healed and the man could walk with only a slight limp.

Mr. NEVITT read a paper on Coca and its Alkaloid. After giving an account of the botanical relations of the plant and its use by the native Indians as a stimulant and narcotic, he referred to its use as a local anæsthetic and gave a list of the surgical operations in which it had been used, including cases of hæmorrhoids, fistula, opening mammary abscess, applying arsenical paste to epithelioma, circumcision, irritable conditions of the bladder, lithotrity, vaginismus, toothache, pruritus ani, lichen, eczema, and in numerous operations on the throat and nose. He had used it himself in four cases. 1. The removal of a vascular growth from the female urethra; a 20 per cent. solution being applied on cotton-wool. 2. A case of *vaginismus* in a newly married woman; the same solution was applied on a pledget of wool, and in five minutes the patient could bear the introduction of a Ferguson's speculum and the application of carbolic acid to two fissures. A vaginal dilator was used frequently, and the patient was enabled in a very short time to return to her husband. 3. He had used it in applying carbolic acid to a fissure of the rectum. 4. In applying nitric acid to a chancroid sore.

Reviews and Notices of Books.

Lectures on Diseases of the Nervous System. By WEIR MITCHELL, M.D. Second Edition. Philadelphia: Lea Brothers and Co. 1885.—We reviewed these Lectures on Diseases of the Nervous System when they first appeared, about four years ago. The second edition has been somewhat enlarged and revised. The difficulties of diagnosis in hysterical disease of joints receive special consideration in the new edition. The chapter on this affection opens with a description of a typical case of hysterical disease of the knee-joint, in which there could be no difficulty in assigning the true origin of the complaint, for the present and past associations of the affection were only too manifest. Difficulty in diagnosis arises, as Dr. Weir Mitchell truly states, when there has been a real injury or true joint disease, and with it hysteria, or this later condition primarily, and inflammatory joint lesions supervening. Then problems of "exasperating perplexity" beset the physician. A case is narrated in which the affected knee was the seat of notable alterations of temperature, as ascertained by a surface thermometer. The sound knee was also investigated, and showed no abnormality. The temperature of the affected joint began to rise about 9 P.M., and was attended with redness, swelling, and tension. The same set of symptoms could be brought about at any time by handling the knee. Ultimately, under the advice of Professor Billroth, the joint was laid open and explored, with a view to obtain ankylosis. But inflammatory exudation in the connective tissues was not discovered, and the ends of the bones and cartilage were found to be normal. "For those who believe that hysteria never gives rise to organic change, this case will certainly be full of instruction." This lecture is by no means an exhaustive one; but, like most of the lectures, the interest lies in the keen insight into the nature of the subject and in the suggestiveness which the author manages to throw into his somewhat sketchy accounts. Other new chapters have been introduced on the relations of hysteria to organic disease of the spine and on the hysterical disorders of the rectum. The lectures must command the thoughtful attention and careful study of all who desire to read what is best in medical science.

The Microtomist's Vade Mecum. By ARTHUR BOLLES LEE. London: J. and A. Churchill. 1885.—This work, as the preface states, is to put into the hands of the instructed anatomist a concise but complete account of all the methods of preparation that have been recommended as useful for the purposes of microscopic anatomy, and so to furnish him with a ready source of information on points of detail as to which his memory or his knowledge may be at fault. It is a work that has been much needed. George E. Davis's treatise on Practical Microscopy, one of the latest books on this subject, deals chiefly with the instrumental part of microscopical work, and, though otherwise good, is deficient in that which relates to hardening and staining tissues for section. Moreover, within the last few years an extraordinary number and variety of processes have been published, some of which are available for almost any tissue, while others are adapted for special organs and objects. The work before us is divided into 660 sections, and almost every section is devoted to a description of some staining agent or process, some material for injection, or some mode of mounting. It is in fact a complete repertory of modern methods. It is well remarked by the author that, notwithstanding the great variety of processes recommended, which are, indeed, almost as numerous as the tissues to be examined, a certain system underlies that variety; the system consisting in the first place of fixing the structures to be examined, then staining them with a nuclear stain, dehydrating with alcohol, and, mounting series of the sections in balsam. In accordance with this principle, the majority of preparations are made by fixing, either with sublimate or a picric acid combination, washing out with alcohol, staining with alcoholic borax-carmine, embedding in chloroform-paraffin, cutting with a sliding *microtome*, and mounting the sections in series in Canada balsam. No microscopist should be without this handbook of the methods of microscopic anatomy, which will supply him with useful information on every subject he may require to know when at his table, and will give him suggestions that he may readily turn to account.

Manual of the Antiseptic Treatment of Wounds, for Students and Practitioners. By W. Watson Cheyne, M.B., F.R.C.S., Assistant-Surgeon to King's College Hospital, &c. With Illustrations. London: Smith, Elder, and Co. 1885.—This book supplies a known want. It is notorious that many who speak and write of the antiseptic treatment of wounds are but imperfectly acquainted with the scientific basis upon which it rests, or the many details in its management upon which its full success depends. Mr. Watson Cheyne's larger work is too bulky for the majority of readers and practitioners. He has done well, therefore, to place the essential considerations and facts within the compass of 150 octavo pages. Having gone carefully through the book, we can confidently recommend it to all who seek to become acquainted with Sir Joseph Lister's method.

Die Methoden der Bakterien-Forschung. Von Dr. Ferdinand Hueppe. Wiesbaden: C. W. Kreidel. 1885.—Modern pathological research has opened up an entirely new field of study, for to be an all-round pathologist nowadays one must be a mycologist also. It is, then, highly necessary that some guidance should be given to those who desire to pursue a study that requires minute observation and most careful manipulation. For this purpose Dr. Hueppe has written a book which covers the whole ground. It is a laboratory handbook, and deals in the first place with the microscopical detection of forms of bacteria with and without the aid of special staining reagents, within diseased tissues and isolated from them. Thence he passes to the next step in all such research—viz., the separation of the bacteria and their cultivation in various media, so important for the detection of specific differences. Then come the inoculation test and its various methods of application. After sections devoted to such subjects as the action of temperature and disinfectants, and the investigation of soil, water, and air, Dr. Hueppe concludes by advocating the formation of bacteriological laboratories in connexion with hygienic institutions. The author has every right to be heard on the subject, and we may be sure that what he says is founded on an extended personal experience.

Darkness and Dawn: the Peaceful Birth of a New Age. London: Kegan Paul, Trench, and Co. 1884.—This is a smartly written little book, containing some fine irony, and wholesome, though sad and sober, truth, dressed in a somewhat Ruskinian garb. Worshippers of the great god Commerce will wince if they read it, and the glorifiers of Trade, as the prime civiliser of the world, will not relish the remorseless fashion in which their idol is demolished. But a revolution, bloodless yet complete, is represented as changing all this. The transformation is inaugurated by a self-denying nobleman, who relinquishes, for the benefit of the State, his possessions, and, his example becoming contagious, the nation of shopkeepers is gradually converted into a real Christian commonwealth, each for all and all for each. Zymotic diseases die out, relentless competition having ceased, the motive for food adulteration no longer exists, whilst all that is noblest and best in human character has full sway. So ends the tale. Gloom, lurid and intense at the beginning, merges into the brightness of a golden age. "So mote it be!"

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

Tuesday, May 12th.

Sir H. Acland, President, in the Chair.

The President, in opening the proceedings of the Council, said:—The session brings the Council together once more with the same constitution and the same functions to discharge that were assigned to it by Parliament in 1858. It has often been remarked, that so long as this is the case we cannot intend nor even wish to abandon the post of duty so assigned and undertaken. On this head, therefore, no more now need be said. At a later period I shall have to make a single observation on an important question arising from the situation in which we are placed. It was lately my happiness to see the Marquis of Ripon, since he returned from his distinguished administration in India. I reminded his lordship that in the fifteen years that had elapsed since he had endeavoured in vain to consolidate the medical examination arrangements of this country, no action taken in that direction by Parliament had been successful, notwithstanding the sincere labours of successive Governments—labours appreciated and often acknowledged by you. But I was able to add with satisfaction that, nevertheless, education had continuously advanced; that many anomalies had comparatively ceased; and that I sincerely believed that there was, upon the whole, an honest rivalry among teachers and between institutions to carry out, by voluntary exertion, the principles by which he had sought to secure the public good. It had been my wish this year to have taken a brief survey of the education and examination changes which, as I understand them, have taken place in these last fifteen years. But since they are still in transition, I shall confine myself to-day to a short account of the present position of the Council's work, reserving a more complete statement for another occasion. My reasons for adopting this course are these. At the last meeting of the Council instructions were given in three directions, each of which had separately much significance, and are, when taken together, calculated to produce a great effect on the course of medical education. The three were: 1. The revision by the Branch Councils of England, Scotland, and Ireland, severally and separately, of the recommendations hitherto issued by the General Council. 2. No person should be granted a degree, diploma, or licence to practise, registrable under the Medical Act, unless he has proved his competency in medicine, surgery, and midwifery, by passing examinations in those subjects at one or more of the licensing bodies. 3. The inspection of the final medical examinations in all the universities of the United Kingdom. Before we proceed to-day to consider in detail the result of the Council's instructions, it may be well generally to note the effect of these instructions taken collectively and in their complementary relation to a Report which as yet has hardly been fully considered—viz., that on the examinations by the corporations in England, Scotland, and Ireland, by Mr. Teale, Professor Gairdner, and Mr. Stokes. The reports on the recommendations having been circulated among the members of the Council, they will have already observed that the several suggestions of each Branch Council have been printed in parallel columns along with the original recommendations of the Council. The General Council can now compare at a glance these Branch Council suggestions with those of the

General Council, and can readily draw in each case their conclusions. The General Council requested each Branch Council to confer as far as it might deem desirable with the several licensing bodies of its division. They all did so, and the several replies of these authorities are appended to each Branch Report. The English Branch decided that it was desirable to give to some of the teachers in the English schools an opportunity of recording their opinions on the several points raised in the recommendations. There are no fewer than twelve separate medical schools in London only, with about 350 accredited teachers; and in the provinces there are as many as nine schools, with about 250 teachers. The English Branch Council decided not to address officially each school as a whole, but only to write to a few individual teachers. Accordingly a small selection was made, comprising representatives of every subject taught, whether in the larger or in the smaller schools. Seeing the great change that has taken place in the last twenty-five years, not only in the ideas but in the apparatus of teaching, some of the younger as well as the older teachers were applied to. It is not without interest to compare some of these replies with those received by the Committee on Professional Education presided over by Mr. Syme in 1869, together with the Report of the London Teachers' Association, presented by their chairman, Mr. John Simon. In the last twenty years, opinions concerning the administration and teaching in the London and provincial schools have greatly changed. The Council, in thus revising and reissuing its recommendations, has, for two reasons, a delicate task to perform. The Council's recommendations have often been assailed from two opposite quarters. First, by those who believe that great institutions—such, for instance, as the Universities of London, Edinburgh, and Dublin—that have worked honourably, and faithfully, and independently in the past, and have with justice acquired a great name, should be seldom interfered with by this Council, and then only in cases of importance, and not in matters of detail. It has often been said, and with truth, that these recommendations are sometimes framed by narrow majorities, and that they touch on points which had better be left to the experience, the progressive experience, of individual institutions. It is therefore alleged that the recommendations should properly be considered as suggestions, and not as orders; that they should, in fact, be regarded in the light of "moral suasion," as it was called by Mr. Syme, with just a touch of the "moral influence," as it is described, of an ironclad in a neutral harbour. But on the other hand, it is said that the recommendations have no value because they cannot be enforced,—and that for this reason the Council is in a false, and it is even said in a humiliating, position. I venture to make a brief reply to both these criticisms—a reply based on observation, and as simple as it is true. The Legislature did not intend this Council to be mandatory in its action. It did intend the Council to be consultatory and hortatory. It was constituted of persons who were entitled to be consulted and capable of advising. It did not intend to relieve the great institutions for the higher education from the responsibility of their trust, or deprive them of freedom to advance on their own lines. It did direct the Council to ascertain whether these did so act, and to report them if they did not. It did call on the representatives of all these institutions to combine in this Council for national consultative and directing purposes, laying aside here, for the common end, their local aims and prejudices, if they had any, which were out of harmony with the general interest. It is easy enough to ascertain whether, and how far, these several intentions have been fulfilled. At no time in history has it been more difficult to fix a standard of education, general, scientific, or practical. Since the Council has existed, the extent of biological knowledge has increased in an unprecedented way; the foundations of therapeutics, the very conceptions concerning prevention of disease, have been enlarged by observation and experiment, and the course of study and examination has been necessarily widened and become more complicated. It became therefore judicious, if not necessary, to seek separately the matured opinions of the independent authorities in England, Scotland, and Ireland, for the purpose of learning their most recent educational views. It has often been stated that there are real differences in the three divisions of the kingdom, which should be taken into account in framing a general scheme. If so, we might hope thus to learn their nature, and how to allow for them, and we may expect now more completely to harmonise the matter as well as the manner of study and examination. That these observations are not connected with an imaginary difficulty, and that it is dangerous for the Council to issue recommendations which cannot be made orders, will appear when letters from the Universities of Oxford, Cambridge, and Dublin are laid before you and discussed. The next instruction of the Council to which attention may be drawn is "That, in the opinion of this Council, no person should be granted a degree, diploma, or licence to practise, registrable under the Medical Act, unless he has proved his competency in medicine, surgery, and midwifery, by passing examinations in those subjects at one or more of the licensing bodies." An observation was lately made on an official occasion to the effect that the issuing of this recommendation showed the need for the reconstruction of the Medical Council, because the Council could not enforce it. The premises and the conclusion both appear to me equally at fault. It is not certain that practically the Council cannot enforce the recommendations; but if a legal authority desire to do its assigned legal duty, and if it is not enabled by the law to do it, then the law should give the powers requisite for carrying out its intentions. In this case a clause of a few lines would give it. But the Council, if it think fit, is able to represent to the Privy Council that having long since agreed with each Government that has affirmed the principle of its recommendation, and having waited for many years for accomplished legislation on this and on other points, it has advised the licensing bodies to carry out the principle of all the amending Bills in this direction. By combination they assuredly can do so. Indeed, to a partial extent, this has been done by the corporations of Scotland and of England, and there is hope that it will be done also in Ireland. In order to ascertain what is the actual condition at present in regard to the registration of single qualifications, the entries made in the Register for a period of six months have been examined by the registrar. Between the 1st of October, 1884, and the 1st of April, 1885, there were registered 175 persons with a single qualification, and of these 175 only 11 have subsequently registered a second. This constitutes about $\frac{5\cdot7}{100}$ of the whole number of registrations, $\frac{4\cdot2}{100}$ of those in England, $\frac{1\cdot3}{100}$ of those in Scotland, $\frac{3\cdot3}{100}$ of those in Ireland. Of those in England, 62 had a surgical qualification only, and 113 only a medical one. Some of the statistics concerning students also are noteworthy. One of the most remarkable is recorded in a table by Mr. Miller in the Student's Register of last year—viz., that the number has increased between 1870 and 1884 from 1160 to 1957. The subject of the statistics of the profession will be brought before you by Mr. Marshall. The inspectors whom you directed to be appointed to visit the final examinations of the universities have begun their labours. A calendar has been prepared of all the examinations to be held during the present year, and whatever further information or assistance the visitors may require in each branch of the kingdom will be from time to time furnished from your office. Each division of the kingdom is to be visited by visitors from the other two divisions. The Council is already indebted to the able persons who have undertaken this task, it must be said, wholly or mainly on public grounds. It would not become me to anticipate the result of their inspections. Yet, it should be now borne in mind that when these reports are examined in conjunction with the report of 1881-2 on the corporations, and when both are compared with your conclusions which will appear in your revised recommendations, and with your resolutions as to excluding single qualifications from the Register, there will be a complete body of statement as to the present condition of the pass examinations, their efficiency, or their shortcomings. At least two important questions will remain—the first, how far the Council can or should inquire, not necessarily for criticism, but for information and suggestion, into the means and appliances for education in the several schools, a question so keenly discussed of late in relation to the teaching in this metropolis and the universities; the second, what shall be the relation of the pass examinations and the registration titles, to the higher examination, and the so-called higher titles. It is an open secret that these higher titles differ greatly in their actual value, and that some are of no value at all. Yet they are eagerly sought after. It will be generally admitted that the aspiration of students after a title supposed to be of higher social worth to some extent affects the educational arrangements of this country. It is possible that a committee might elicit information which would show this kind of disturbance to be an evil either more or less than is supposed. But the agitation to obtain the title of doctor by new channels, or on easier terms by old ones, shows that the students have sometimes a motive other than that of obtaining more knowledge or proving the possession of higher acquirements. I cannot wholly pass by without notice a Bill, introduced into Parliament by Dr. Lyons, Mr. Gibson, and Mr. Plunkett, to enable the College of Physicians of Ireland to register a title not included in Schedule A of the Medical Act, 1858, and to enable universities to register the title of master in midwifery, and master of obstetrics, or master in obstetric science. Nor can I omit to notice the action taken lately by the University of Oxford in the way of utilising the diplomas of surgery of the Royal College of Surgeons rather than institute at present a new surgical title in England. Both actions are useful as calling attention to the vexed question of the real or imaginary evil of numerous qualifications—an evil which would be almost imaginary, supposing that all education and all examinations could be exactly equal. I pass to another topic—that, namely, of the questions which arise under the penal clauses of the Act. Sooner or later these clauses will demand revision. The Council in its early days declared that it had not the duty of a prosecuting body; and on May 24th, 1877, it came to the conclusion that after mature deliberation it saw no cause for the determination then arrived at. Its legal functions in regard to prosecutions are administrative and judicial. Inasmuch as illustrations of this fact will appear during this session, the subject need not here be considered in detail. It is now sufficient to note that there is a tendency to exercise pressure on the Council to undertake criminal inquiries. There is, perhaps, no great willingness on the part of the Public Prosecutor in England to take this work off our hands. On this matter the Council's solicitor has full information at your disposal. Thirteen cases of alleged misconduct by registered practitioners have been referred in the past year to the solicitor. Almost all these cases have been complaints against men professing to be qualified who are not qualified, or men who are qualified but act with unqualified persons either as partners or as assistants. They are usually cases which would, *primâ facie*, justify investigation. The complainants generally desire the Council to take up the inquiry, or to pay their solicitor to do so. Their view is that it is the duty of the Council to undertake prosecutions, even against persons who are not on the Register, as well as to punish *proved* offenders who are on it. Mr. Farrer has observed to me that though there may be cases in which the Council might properly undertake prosecution, it should not be the rule upon every charge brought before it. The Council are judges with a formidable power of severe punishment without appeal, but they cannot compel sworn testimony; the machinery for hearing cases and sifting evidence is cumbrous, expensive, and involves serious loss of time; and their only sentence, removal from the Register—for they cannot suspend—may be much the same as ruin. It is Mr. Farrer's *opinion* that offenders should be summoned, when the cases against registered practitioners are so far complete as to be without doubt in the absence of satisfactory explanation. Some of the cases are certainly such as should be brought before the ordinary tribunals. It is much simpler to judge of the professional misconduct in a case that has been tried for some offence according to law, and legally convicted. Several years ago the President of the Board of Trade brought two cases of drunkenness before the Council, and the Council declined to interfere. The Council then thought that it could not undertake to investigate charges of drunkenness. Yet such charges might involve cases of the gravest dereliction of duty—and they, in this instance, did so. But the Council then thought it was a case with which the Government should deal. Perhaps, too, it felt that, grave as the offence of drunkenness is, the only punishment the Council can inflict—viz., removal from the Register, and, in that way, the loss of the civil rights of a profession—is an excessive punishment. I must not pursue the question whether the several corporations have to exercise the same caution, or are under a greater obligation to strike the names of the persons so offending from off the roll of their members. This subject will appear again in the case of a Scottish practitioner, charged at the last meeting with issuing certain newspaper advertisements. Further correspondence on this matter will be laid before you. I have to congratulate you on the approaching completion of the new edition of the British Pharmacopœia, to which Dr. Quain has given so much zealous attention. It would not become me to attempt to describe the value of this work, and the might of Dr. Quain's labour upon it. In conclusion, I wish to express my conviction that the zeal and energy of the rising generation of teachers in our medical institutions are grappling with the advancing mass of biological knowledge in a manner which, if ever equalled, has never been surpassed; and that the chief fear for the ordinary medical student of the end of this nineteenth century is that he will be oppressed by details in many departments of science, which, though important to the expert, the specialist, and the discoverer, and attainable by exceptional men, are an actual source of distraction to the ordinary clinical student in the precious and too brief years of his student life. Whether Parliament will alter the constitution of the Council, whether it will extend its powers, or whether it will leave it still, with enlarged experience and single intention but without more power to do its work, are questions which I leave to others to discuss. In both political parties of the State there are men of energy too great, perseverance too steady, and public spirit too strong, to be daunted by past difficulties, or to be wanting in the will to give us whatever is needed as soon as our institutions have agreed among themselves to work unitedly with the same zeal that they have ever shown for their individual progress and development; for no political party is able to destroy the independence of institutions while they fulfil their function according to the true idea of a State. But if they do not, or if they are victims of internal dissension, neither party will refrain from seeking to substitute for their old independence the growing force of rigid State control.

Mr. MARSHALL, in moving that the address be entered on the minutes, said he had never heard an address from the chair which contained more important and weighty matter.

Dr. HUMPHRY seconded the motion, which was agreed to.

The Finance Committee having been appointed, the following members of the Council were elected by ballot on the Executive Committee:—Sir H. Pitman, Mr. Simon, Dr. Haldane, Dr. Humphry, Dr. Quain, and Dr. Aquilla Smith.

A table was received showing the results of professional examinations held in 1884 for qualifications granted under the Medical Act by the bodies named in Schedule A.

A table was received showing the number of exceptional cases that occurred during the year 1884 under Clause 20 of the Council's Recommendations on Education and Examination, together with a statement of the action taken thereon by the several licensing bodies.

A table was also presented showing the results of preliminary examinations in 1884, compiled by the registrar from such returns as had been supplied by the examining bodies.

Dr. HAUGHTON moved that the table be referred to a committee. He called attention to the fact that several bodies had sent no information to the Council on the subject, and said he thought that the returns should be sifted in committee before being considered by the Council.

The motion was seconded and agreed to.

The usual returns from the Army and Navy Medical Departments were received and ordered to be entered on the minutes.

A table was received showing the results of professional examinations in 1884 for qualifications granted under the Dentists Act; also a communication from the College of Preceptors showing the results of the preliminary examinations of the College in March last.

Dr. PITMAN called attention to the circumstance that the returns from the College of Preceptors showed that there was almost every year a larger percentage of rejections.

Dr. HAUGHTON said it appeared from the returns that out of 317 students only twelve had passed in mechanics, a circumstance that seemed, he thought, to indicate that there was something in the case of mechanics which the regulations of the Council had failed to reach.

A communication was received in regard to the case of a registered practitioner against whom a complaint had been forwarded to the General Registrar by the Branch Council for Scotland. The Branch Council urged the importance of having the case ready to be dealt with at the present meeting of the Council. The Council deliberated on the subject in private, and were so engaged during the remainder of the sitting. It subsequently transpired that the Council resolved, while sitting in private, that Daniel Sutherland be summoned to appear before the Council on Tuesday next, and also that the name of George Washington Evans be removed from the Medical Register.

WEDNESDAY, MAY 13TH.

Sir HENRY ACLAND, President, in the Chair.

A communication was read from the secretary of the Royal College of Surgeons of England, stating that the diploma of member of the College issued to Mr. Ebenezer Bryceson on April 26th, 1884, had been declared to be void, and that he had ceased to be a member of the College in consequence of it having been proved that before his admission to the final examination he produced forged certificates of professional study.

On the motion of Mr. MARSHALL, seconded by Mr. SIMON, the qualification of Mr. Bryceson as member of the Royal College of Surgeons of England was ordered to be erased from the Register.

Dr. HUMPHRY stated that Mr. Bryceson appeared on the Register as a M.B. of Cambridge University, but as far as he (Dr. Humphry) knew, he had never taken that degree.

The REGISTRAR said that when Mr. Bryceson came to the office he produced what purported to be a document evidencing his qualification, and he filled up the usual form with his name and address as a M.B. of the University of Cambridge.

Dr. HUMPHRY said he would bring this matter before the Council to-morrow.

A letter was read from Dr. J. Wyllie, secretary to the Royal College of Physicians, Edinburgh, stating that at the quarterly meeting of that College, on Nov. 4th last, Bentham Paynter Morison, licentiate of the College, had been deprived of all his rights and privileges as a licentiate, he having been convicted in the Supreme Court of Adelaide, South Australia, of conspiring to cheat and defraud the Australian Alliance Insurance Company, and sentenced to one year's imprisonment with hard labour. At the same meeting of the College similar action was taken with regard to Thomas Robert Horton, who had been convicted in Adelaide of conspiring to cheat and defraud the Australian Mutual Provident Society, and sentenced to two years' imprisonment with hard labour.

On the motion of Dr. HALDANE, seconded by Dr. HERON WATSON, the qualifications of Mr. Morison and Mr. Horton as licentiates of the College of Physicians, Edinburgh, were ordered to be erased from the Register.

Dr. HERON WATSON drew attention to the fact that in October last it was decided that Mr. Horton's qualification as licentiate of the Royal College of Surgeons, Edinburgh, should be removed from the Register, but it still appeared.

The REGISTRAR said that it had been erased from the manuscript register kept in the office, and it was simply a printer's error that it still appeared in the printed book.

On the motion of Dr. HERON WATSON, seconded by Dr. HALDANE, Mr. Horton's name was ordered to be erased from the Register.

Communications were read from the Registrar-General of Wellington, New Zealand, stating that Francis Goold, registered as member of the Royal College of Surgeons, England, 1853, had been erased from the New Zealand Medical Register in consequence of his having been convicted of felony at Auckland on Dec. 2nd, 1876; and that the name of Lloyd Davenport Parry, registered as licentiate of the Royal College of Surgeons, Edinburgh, 1871, had also been erased from the New Zealand Medical Register, in consequence of his having been convicted of manslaughter, and sentenced to four months' imprisonment in the public gaol at Dunedin. It was decided to refer these cases to the Royal Colleges of Surgeons of England and Edinburgh respectively.

A letter was read from Mr. Farrer (solicitor to the Council), stating that Daniel O'Hara, alias Owen Patrick O'Hare, had been condemned to ten years' penal servitude for levying black mail.

The REGISTRAR stated that he had received an extract from the *Liverpool Mercury* of May 9th, from which it appeared that Mr. O'Hara had committed suicide in Walton Gaol, by hanging himself with a towel.

The Council resolved to await further communication from their solicitor before coming to any decison on this question.

Some correspondence was read between the Executive Committee and the Irish Branch Council. A resolution was adopted by the Executive Committee on Jan. 23rd, 1885: "That in the opinion of the Executive Committee it is desirable that the several Branch Councils should contribute the funds required for carrying on the business of the General Council at such times as they may be required to do so by resolution of the Executive Committee." In answer to a communication to that effect, the registrar of the Irish Branch Council had written, stating that at a meeting of that branch on March 24th it was resolved: "That this Branch Council are not prepared to forward the funds at such times as they may be required to do so by resolution of the Executive Committee."

Sir HENRY PITMAN said that it was quite time that some better arrangement should be made with regard to the funds which were provided for the payments of the expenses of the Council. When he was appointed one of the treasurers he found that there was no money whatever to deal with. No account stood in the bank in their names, and very little money was received during the year on behalf of the Council. It was therefore rather an anomaly to have two treasurers. In the returns presented to the Houses of Parliament for the year ending Jan. 1st, 1884, the contributions by the English Branch Council to the General Medical Council appeared as £1682, by the Scotch Branch Council £636, and by the Irish Branch Council £473, but those contributions were never furnished. Every year they were returned as facts, but they were not so; it was evidently an irregularity. It was really a debt due, and he had no doubt that the Irish and Scotch Branch Councils might be trusted to pay the amounts at their convenience, but they did not do so during the year. On the other side of the account, the cash balance in the bank in favour of the Scotch Branch Council was £900, less due to the English Branch Council £636, which was credited as having been paid during the year before. The expenditure of the General Medical Council amounted to £3014 5*s.* 7*d.*, and the receipts out of which the treasurers had to pay that amount were £221 14*s.* 8*d.* Even that £220 was not in the treasurers' hands in the beginning of the year. It was derived from the sale of Registers and Pharmacopœias, &c., so that the treasurers started with the liability of the rent and expenses of the office. Some of the members of the Council would recollect that there had been occasions when there had been no money to pay their fees at the conclusion of a session, the Branch Council not having sufficient funds in hand, and the members had to wait for their cheques. The English Branch Council were not bound to advance £3000 a year for the General Council's expenditure. This, however, was too delicate a matter to be dealt with in the Council, and he therefore proposed: "That the communications with the Irish Branch Council be referred to the Finance Committee, and that the Finance Committee be requested to submit to the General Medical Council a scheme which will render it unnecessary in future that the Branch Council for England should advance the money required to meet the current expenses of the General Medical Council." In dealing with the national funds, the Chancellor of the Exchequer at the beginning of a year provided for payment of all his accounts, and he did not see why the Council could not do something of the same kind. Why could not the Finance Committee make a forecast, and say, "During the year we shall want so much." Each Branch Council would then pay its proportion, and the General Council might open an account at the Bank of England, from which it could draw its money to pay expenses.

Dr. HAUGHTON seconded the motion. He considered that the present relations with the Branch Councils were most unsatisfactory. The only fault he found with the Executive Committee was that they had not enough knowledge of the English language to use the right verb. If they had "requested" instead of "required," the difficulty might have been settled at once; but he allowed no man to "require" him to do anything. It was, however, quite reasonable and proper that the Irish Branch Council should advance the money, and they were quite willing to do so.

Mr. MACNAMARA reminded the Council that some years ago a committee, of which he was chairman, strongly recommended that all the money of all the Branch Councils should be given to the General Medical Council. The English Branch Council objected to that, because at that time they had a large sum of money; but one-half of it lawfully belonged to the Irish and Scotch Branch Councils, because it was derived from registering in London degrees conferred in Ireland and Scotland. Many years ago the grievance was ventilated, and in some cases the English Branch Council was called upon to refund the money to the other Branch Councils.

The resolution was agreed to.

A letter was read from the Secretary of State, requesting information as to "upon what conditions foreign doctors are allowed to practise in England." The information was required by the Danish Minister.

The Registrar was directed to forward to the Secretary of State the clauses of the Medical Act bearing upon the subject.

Communications were laid before the Council from the India Office, the Army Medical Department, and the Navy Medical Department, relating to returns which the Council had asked for.

On the motion of Dr. Struthers, seconded by Dr. Haughton, the Registrar was directed to thank the Secretary of State for India for his communications, and to state that a return applying to the examinations for the Indian Medical Service held in London, similar to that furnished to the Council by the Army Medical Department, would be satisfactory to the Council.

Mr. Marshall moved: "That a committee be appointed to superintend the preparation of statistical returns relating to the medical profession of the United Kingdom; that the committee be empowered to expend on these investigations such sums as may be sanctioned by the President and Treasurer." There were, he said, several subjects which might be usefully considered by the proposed committee, as to which the Council had full information in its possession; and nothing would render the proceedings of the Council more valuable than complete statistical returns with reference to those subjects. One of them was the question of waste and supply in the profession, with regard to which opposite opinions had been expressed. Another related to the career of medical students; and a statistical return on the subject, like that made by Sir James Paget with reference to the career of a thousand students at St. Bartholomew's Hospital, would be both interesting and useful. The duration of study was also a matter of interest, as to which statistical returns could be made by the Council; and the results might show whether fresh legislation was necessary. Another matter for inquiry was the question of single qualifications, and the number of persons taking additional qualifications. So far as the present partial statistics went, it appeared that there had been a gradual reduction of single qualifications from 26 per cent. to about 14 per cent., but more complete information on the subject was required. Other questions would also suggest themselves to the committee as fit subjects for statistical returns, and he thought that a good deal of useful information would result from their labours. The expense of the inquiry would be slight, and the Registrar would be able to render valuable assistance in its prosecution.

Mr. Simon seconded the motion, which, he said, had his cordial support and sympathy.

Dr. Struthers asked if Mr. Marshall had any controversial object in view in his proposal, and suggested that the subject should be postponed until a more definite statement was made of the nature of the statistics proposed to be obtained. He also thought that the committee, if appointed, should be a larger one than had been suggested. A committee of three would be too small.

Dr. Haughton supported the motion, and said he thought that the proposed statistics would prove very interesting to the profession and the public. The discretion of the committee might be trusted as to the particular subjects of inquiry.

Dr. Duncan also supported the motion, but wished to have the opinion of the treasurers as to whether the expenditure involved would be a legitimate one.

Sir H. Pitman said, if it could be shown that the inquiry was for the purpose of the execution of the Medical Act, the expense would be perfectly legitimate.

Mr. Macnamara supported the motion, and suggested as a subject of inquiry the question where students have been educated with reference to where they have been registered. The result, he thought, would be surprising, and would show how it was that the English Branch Council was so rich, and that the Irish and Scotch Branches were so poor.

The President pointed out that the work of statistical returns had been well begun by the Registrar, and would no doubt be usefully extended by the proposed committee.

The motion was agreed to.

On the proposal of the names of the committee—Mr. Marshall, Dr. Haldane, and Dr. A. Smith,—

Dr. Struthers again urged that the committee should be larger; but, after a short discussion, withdrew the suggestion, and the committee was appointed.

Communications were read in regard to the General Medical Council's amended regulations for the preliminary examinations of medical students from the University of Dublin, the University of Oxford, the University of Cambridge, and Queen's College, Cork.

Dr. Haughton said that the letter from the Dublin University had been carefully considered, having been drawn up by himself and amended by the provost of Trinity College. It would be seen that the University peremptorily rejected the mode of teaching and examining in mechanics proposed by the Council, and said that they were not prepared to alter their method, which they regarded as superior to the one which the Council had recognised. None of the bodies had given a more hearty support to the Council than the University of Dublin when it saw that the proposals of the Council were an improvement on existing methods, and it was still willing to recognise the paramount authority of the Council on subjects relating to the final examination. But in regard to subjects of the preliminary examination, mechanics, physics, &c., the Council ought not to expect the University to abandon its well-considered plan of teaching. On all matters connected with the professional curriculum it was ready to yield, but not in regard to subjects of general education. If the resolution passed by the Council at its last session were continued, the students would cease to appear on the Students' Register. That would not be desirable, because the students would be able to say that they had ceased to appear there because they aimed at a higher education, and it would lead to the supposition that the Register only contained the names of minimum educated students. Under the circumstances he did not propose to vote for the motion about to be brought forward by Dr. Humphry.

Dr. Humphry proposed: "That the examinations in education conducted by the universities be accepted as heretofore, but that if in any of these examinations the subjects of elementary mechanics of solids and fluids are not included, a knowledge of these subjects should be required at a subsequent examination." The President, he said, had in his opening remarks stated that the Legislature had intended the Council not to be mandatory but hortatory, and if that applied to medical studies *a fortiori* it applied to general studies. It could never have been the intention of the Legislature that the Council should be mandatory on the university in reference to general studies, and still less to the particular mode in which an examination in English should be conducted. The great work of the universities was connected with the general education of the students, and the examinations were conducted in what was considered the best manner by men who had given their lives to the consideration of the subject. The Council had almost always taken that view: it had been anxious that the general education of students should fall into the hands of the universities, and had passed several resolutions to that effect. The examinations conducted by the universities were of a high order, the requisites for admission to the Students' Register being considerably beyond the requirements of the Medical Council, and that the Council should refuse to sanction the examinations because they were not in accordance with its own inferior plans seemed scarcely credible. Every student was examined in Greek as well as Latin, and his knowledge of English was shown by the manner in which he wrote it, which was perhaps the best possible test. He had formerly proposed a similar resolution to that which he now brought forward: but it was suggested that the universities should be requested to give the Council their opinions on the subject. They had done so, and they had given the only answer which could be expected from them.

Dr. Chambers, in supporting the motion, said that the Oxford University had always held that grammar (with logic) was an essential part of education, and that it was best taught by the Latin grammar. It was not likely that the University would change its method at the request of the Council.

Mr. Simon said it was very disappointing that, after giving up a large portion of the last session to the consideration of the subject, they should now be returning to it. It would be impossible to do justice to Dr. Humphry's motion until after the proposed discussion on professional education. He strongly sympathised with the view taken by the University of Oxford as to the undesirability of instituting a special examination in English, which, indeed, he regarded as a delusion. The University stated: "We do not think that the literary character of medical students will be lowered by your not insisting on a special English examination in the case of Oxford students." The question of physics had been before the Council on several occasions, and the view that it had taken was that elementary mechanics should be a part of the earlier education of students, and be passed before registration; but to press such a regulation in the case of the universities, where the subject was taught *in extenso*, was futile and ridiculous. The point on which the Council had continually insisted was that the purely medical curriculum, treated as a minimum, should be relieved from the subject of physics. If five or six years were given to medical education, time could no doubt be spared for a full course of physics, but that was not the case when the medical course only extended over forty-five months.

Sir H. Pitman said he could not help feeling great surprise that the subject should be discussed in the Council in the year 1885, seeing that as early as 1859 it had resolved "that examination on general education should be eventually left entirely to the examining boards of the national educational bodies recognised by the General Medical Council;" and similar resolutions had been passed at subsequent periods. If the Council was of opinion that the examinations in general education should be left to the universities, why should it now be discussing the question whether the examinations of the universities should be recognised by the Council? It could hardly have been the intention of the Council to lay down the precise subjects of examination in general education at the universities; and if it had done so, he doubted whether the universities would accept any such arrangement. The Council had been all along urging the universities to conduct the examinations, and now that they were doing it exception was taken to the mode in which they were proceeding, and it was proposed to refuse recognition on the ground that the examinations did not include mechanics.

Mr. Teale thought that the Council would be placed in an absurd position if it declared that the university examinations were not sufficient for its purpose.

Dr. Watson said the subject had been thoroughly threshed out on previous occasions. They had again and again expressed their confidence in the action of the universities and their competency to conduct examinations for preliminary education, and it was hard that those bodies would not do what the Council required, but would insist on doing something that the Council did not want. There was no reason why a student who had passed a higher examination should not have a separate examination for mechanics, in order that all medical students, wherever taught, might be placed on the same footing. To have a student coming up without having passed the examination in elementary mechanics created extreme confusion in regard to all licensing bodies, and there was an uncertainty as to whether the student still required to be subjected to such an examination before he was permitted to go in for a professional examination. Again and again men had come up for the professional examination, and after they had passed it had been discovered that they had not passed the examination in elementary mechanics. There ought to be one rule for all students, whether coming from the universities or elsewhere; and if the universities would not conduct the required examinations, there were other bodies that would. If the universities carried out their threat, and allowed their students to go on without registration, all he could say was that those students might undoubtedly obtain university degrees, but they would not be able to obtain licences to practise from the corporate bodies. If the Council had, after repeated consideration, come to a definite conclusion on the subject, it ought to adhere to it until it had a better reason for reversing it than that the universities declined to accept it.

Dr. Struthers said that the Council had already by a large majority passed a resolution as to English, and it was absurd to ask it six months afterwards to reverse its decision. The Council had also decided that elementary mechanics should be passed before registration, and it would be a complete waste of time to reopen the question. The only reason for reconsideration was the opinion expressed by the universities. What would be said if one of the Scotch universities had tried to defy the Council in the same way? Surely, the universities could easily institute examinations in the required subjects; and if they would not, there was the College of Preceptors, whose examinations met all the requirements. He moved as an amendment: "That in reference to the letters now received from the University of Dublin, the University of Oxford, the University of Cambridge, and from Queen's College, Cork, the Council sees no reason to depart from the resolutions adopted at the last meeting in regard to preliminary examination for the registration of medical students."

Dr. Watson seconded the amendment.

Dr. Pettigrew supported the amendment, and expressed a hope that Dr. Humphry would withdraw his motion.

Dr. Banks supported the motion. The Oxford examination in English was perfectly adequate; and as to Dublin University, it could not be expected to alter its regulations at the bidding of the Council.

Dr. Duncan, in supporting the motion, said it would be preposterous for the Council to say that they would not be satisfied in regard to English with what satisfied the University of Oxford. The difficulty as to elementary mechanics, which was not included in the preliminary examination at the University of Dublin, would be easily overcome by Dr. Humphry's proposal that the subject might be taken in a subsequent or separate examination.

Dr. Haughton said there was no desire on the part of the universities to act offensively towards the Council. As to the subject of elementary mechanics, it ought to be taught in the same way to all students, whether medical or otherwise; and at present it was certainly not taught efficiently in the schools.

The debate was then adjourned.

Thursday, May 14th.

At the meeting of the Council to-day, the debate on Dr. Humphry's motion was resumed, and after some further discussion the motion was agreed to in the following modified form:—"That the examinations in general education conducted by the universities be accepted as heretofore; but that if in any of these examinations the subject of elementary mechanics is not included, a knowledge of that subject be required at a separate preliminary examination." The amendment of Dr. Struthers was withdrawn. A report was received from the Pharmacopœia Committee with a revised copy of the new Pharmacopœia. A cordial vote of thanks was given to Dr. Quain for his valuable labours in connexion with the work. A report was presented from the Committee appointed to make inquiries as to possible sites available for the purposes of new offices for the Council. The Committee reported in favour of a site on the Savoy estate of the Duchy of Lancaster. The general feeling of the Council was adverse to the suggested change; and after discussion it was resolved to refer the report to the Executive Committee, with power to take steps to improve the ventilation of the hall in which the Council meets; or, if necessary, to report on the improvement of the building at the next meeting.

Dr. Pitman then moved: "That a committee be appointed to consider and report in what way, if any, the accumulated funds of the General Medical Council can be applied in promoting scientific research for the public good."

The debate on the motion was adjourned, when the Council rose.

STRANGULATED OMENTAL HERNIA.

To the Editor of The Lancet.

Sir,—I regret to have overlooked until to-day Mr. Treves' letter in your impression of April 25th. But I do not propose, at present at all events, to repeat, extend, or multiply the arguments I can muster, having already been favoured, on May 17th, 1884, and April 25th last, with space ample for the purpose. In the communication of a year ago Mr. Treves will find, I think, the answer to his objections. But even should he not be convinced on reading it again, I would prefer to wait till, as he well puts it, my "arguments have been supported or opposed by more extended clinical data, and when they have met fully the test of the post-mortem room." I am glad that he has taken up the subject, for the more it is noticed the better its chances of thorough ventilation, not so much on paper as in the thought and practice of surgeons, in the presence of illustrative cases.

I am, Sir, yours truly,

Rushton Parker.

Liverpool, May 10th, 1885.

THE LANCET.

LONDON: SATURDAY, MAY 16, 1885.

THE most interesting event which has transpired up to the present time at the meeting of the Medical Council is the Address of the President, Sir Henry Acland. The number of the subjects lightly touched upon give interest to the speech. The President's gentleness of touch is his great quality. One occasionally comes to a point at which strength and determination of language would be a relief. Failures, delays, and disappointments, that move less serene men than Sir Henry, only bring out his imperturbable suavity; and the most imperfect settlement of public questions, over which the profession grieves, he views with an equanimity such as Darwin might display over the slow processes of Evolution. In the early part of his address he recalls the happiness with which he had met the Marquis of Ripon, and had reminded his lordship of his efforts fifteen years since in favour of medical legislation. It is all just where it was where the Marquis left it. Nineteen corporations are all fighting for their own hand, and the weak hand of Parliament has been shown to be powerless in the matter. But to Sir Henry Acland's happy mind there is no disappointment in all this. He told the Marquis that he sincerely believed that though he had failed, thanks to the honest rivalry among teachers and between institutions, "the principles" were being carried out, and the public good secured. We can only look on at a distance and admire this power of seeing unmixed good in the failure of all Governments to accomplish what the Government and the profession thought necessary for the public good, and what a Royal Commission recommended. The report of the interesting incident of a conversation between the Marquis and the President would have been a little more interesting if Sir Henry had told us the Marquis's views of the situation and of the obstinate resistance of the medical authorities to changes for the public good.

The first day of the Council's meeting was occupied very largely with the discussion of a case of alleged misconduct. It is very painful to find from the President's address that no less than thirteen cases of alleged misconduct by registered practitioners have been referred in the past year to the solicitor. These largely have reference to unqualified practice—registered medical men acting with unqualified persons as partners or assistants. We have often cautioned medical men against conduct of this kind, which brings the profession into discredit and its members often into positions of much embarrassment. The Council will have the full approval of medical men generally in exercising its judicial powers against members of the profession who act unworthily. It is unsatisfactory to notice from the President's address that there is still much uncertainty and difference of opinion as to where the duty and power of prosecuting offenders should lie. The Corporations seem very reluctant to vindicate the honour of the profession, though always ready to tell Parliament that their moral influence alone preserves the high standard of professional opinion and conduct. The Public Prosecutor shows great unwillingness to do work for which, one would suppose, he was brought into existence. And the Medical Council, from its earliest days, has discouraged the idea that it had any prosecuting function. In regard to this duty of prosecuting for breaches of the Medical Act, all the parties that should have acted have made excuse, and too often the work has had to be done by private medical men or medical associations organised for the purpose. Since the Home Secretary, in his plain way, expressed his opinion that the Medical Council has duties of judgment in regard to such cases, the judicial functions of the Council have come into more frequent action, and a great part of the present programme is filled with motions having reference to cases of alleged misconduct. In one such case, as will be seen by our reports, the Medical Council has erased from the Register the name and qualification of George Washington Evans, who was no less than a Fellow of the Faculty of Physicians and Surgeons of Glasgow. His publications and advertisements on the subjects of diseases of women and debilities of the generative organs constituted, in the opinion of the Faculty, "infamous conduct in a professional respect," and led to the erasure of his name from the Register of Fellows on December last. The Medical Council has endorsed the action of the Faculty.

The inevitable discussion on Preliminary Education has begun; but it really seems as if the Council was going to be deprived of the pleasure of its full development on this occasion. Some of the members begin to see that there is something bordering on the jocose in its treatment of this subject. Not only does it turn up annually, but, as Sir Henry Pitman showed on Wednesday, the continuous idea of the Council from its first meeting in 1859 has been to rid itself of all responsibility in regard to preliminary examinations, having voted repeatedly in favour of leaving them entirely to the Universities and other national educational bodies. But having almost effected this result, they keep on worrying these bodies, and dictating to them how to do the work. The consequence is not only that the Council wastes time which it might well devote to improving strictly medical education, but it receives protests from the Universities which, though couched in polite language, are not destitute of pungency.

◆

THE *American Journal of the Medical Sciences* for April contains a careful and useful paper, by Dr. Winslow of Baltimore, on the Operative Treatment of Pyloric Stenosis. In the forefront he places pylorectomy, and gives a table of sixty-one cases of this operation. From it we learn that there have been sixteen recoveries and forty-four deaths, while in one case the result is not given. Billroth has operated eleven times, with success in six cases, and his results are the best that have been yet attained by any surgeon. The mortality in cases of cancerous stricture of the pylorus has been 76 per cent. The factors which seem of chief importance in determining the result of the operation are the age and general condition of the patient, the existence of extensive adhesions between the pylorus and the neighbouring organs, particularly the pancreas, and the length of time occupied in the operation. The younger the patient the greater the power of resisting collapse. The presence of adhesions not only greatly adds to the difficulty of the operation, and therefore to the time required in its performance, but it renders the danger of hæmorrhage and of subsequent peritonitis greater; while in some cases gangrene of the transverse colon has occurred owing to removal of the omentum and transverse mesocolon. Nearly 50 per cent. of the patients operated upon have died of shock within twenty-six hours, and of the cases which have recovered not one has lived for three years without recurrence of the disease when the operation has been done for cancer. Gastro-enterostomy, by which the stomach is made continuous with the small intestine beyond the pylorus, has been performed thirteen times during the last four years. Of these nine have died within a month of the operation, and four, or just over 30 per cent., have recovered. This is a better result than was obtained in the early cases of pylorectomy; and when it is borne in mind that the operation has been done in cases of cancerous and other strictures of the pylorus, in which the adhesions have been so extensive as to render impossible or nearly impracticable the operation of pylorectomy, it is evident that the balance in favour of gastro-enterostomy is greater than the mere figures show. The operation consists in raising a loop of small intestine and, after making an incision into its free border and into the stomach, uniting them by sutures. It is thus a shorter and simpler operation than pylorectomy, and does not expose the patient to the same risks from shock or hæmorrhage. It has been urged against it that it is in no way radical, that it only palliates the disease, and allows the new growth to extend and exert its deadly influence upon the system. This is no doubt true. But, on the other hand, it is to be remembered that the success in the radical cure of cancer in the situations most favourable for it has not been such as to render it probable that surgery will ever be able to cope effectually with this disease when it attacks the stomach, and the results of pylorectomy thus far point in the same direction. Gastrotomy, gastrostomy, and duodenostomy have all been performed for cancer of the pylorus, but, for various reasons, are sure not to be widely practised or even repeated again. *Digital divulsion of the pylorus*, or Loreta's operation, has been practised with great success for cicatricial stricture of the pylorus. Of five completed cases three recovered, and a sixth case was doing well three days after the operation. It is, of course, quite unsuited for cancer of the pylorus, but in cicatricial stricture of that orifice it gives speedy and complete relief, and the procedure appears to be free from much of the danger attending the graver operations we have been referring to. Among Dr. Winslow's conclusions, which, we believe, are thoroughly supported by the evidence at hand, are these: that pylorectomy for carcinoma should only be performed in the limited number of cases where, with marked stenosis, the pylorus is not adherent to the neighbouring structures and the patient is young and fairly strong. In other cases of cancerous stenosis gastro-enterostomy should be performed. In cicatricial stenosis digital divulsion of the pylorus should be performed when the symptoms are sufficiently severe to demand operative interference.

◆

Discredit was for a long time cast on the attempts to explain the prevalence of certain epidemic diseases by referring them to meteorological conditions, and this was to a great extent deserved, because those who at that time interested themselves in this subject were content to assert that this or that epidemic owed its prevalence to what they were pleased to term "climatic" or "telluric" influences, without any apparent effort to ascertain or explain what were the precise conditions which had been operative, and which were disguised under such general terms as we have referred to. During later years, however, the attempts to ascertain how far meteorological conditions influence the prevalence of disease have been on a much more scientific scale, and medical officers of health are, in their annual reports, now in the habit of making records bearing upon this influence, which cannot fail in the long run to be of material value. Mr. C.E. Paget, medical officer of health for the Westmoreland Combined Sanitary District, makes a contribution to this subject in connexion with a detailed review of the prevalence of "fever" in the borough of Kendal since the passing of the Registration Act. During the early portion of the period referred to, "typhus" was the prevailing fever, but it gradually changed its name as years went on, until it became evident that, although typhus might not have been altogether absent at certain periods, it was really enteric fever that Kendal has had to deal with. During the decade 1842-51 the mean annual "fever" mortality per 1000 of the population was 1·58; in the decade 1852-61 it was 0·70; in the decade 1862-71 it was 0·41; and during that ending 1881 it had further fallen to 0·26. The steady decline in the mortality is attributed in the main to the progressive sanitary improvements which have taken place, but when the separate prevalences which examination of the death-rates exhibit are studied it would appear that other influences have been at work; and Mr. Paget has made every endeavour to ascertain how far these influences may have had to do with prevailing meteorological conditions. The value of the earlier records available were found to be much affected by the circumstance that only the mean annual variations could be learned, and so it comes to pass that as regards rainfall, for instance, whilst it is almost undeniable that in Kendal there have been occasions when an excessive fall of rain has been associated with a rise in the prevalence of enteric fever, yet mean annual records alone do not help much in deciding the question. Such mean records as to the state of the barometer are still less helpful, and hence, although Mr. Paget is convinced that sudden depressions in the mercury, especially when associated with excessive rainfall, have favoured special prevalences of this fever, yet he is obliged to base his opinion rather on certain recent occurrences than on any observations extending over a series of years. The temperature records, though also limited to annual means only, were found to be a little more helpful, the rise and fall in the total mortality from continued fever corresponding in a more or less degree with a rise and fall of the mean annual temperature in twenty-nine of the years between 1838 and 1881; variations to the contrary only being indicated in four of the remaining seventeen years. In view of the imperfect means at his disposal, Mr Paget does not attempt to lay down any general conclusions, and it is evident from his report that he would be the first to admit that when meteorological conditions influence the rise and fall of the mortality from any special disease, this influence may be largely, if not in the main, brought about by the operation of these conditions on purely local states, which, being absent elsewhere, might prevent any similar conclusions being arrived at in other places. Thus, in one special outbreak of enteric fever which is several times adverted to, it seems all but certain that the conditions of sewerage which existed at that time in Kendal constituted a local state on which meteorological changes could operate with special force. The incidence of the disease fell chiefly on a portion of the town having deficient sewer ventilation, and it is precisely under such circumstances that heavy rainfall, which would force foul air out of the sewers at every available weak point in the system, together with a diminution of barometrical pressure which would aid in the expulsion from the soil into the atmosphere above of any accumulation of foul air from sewers or elsewhere, would tend to bring about one of the very conditions so well known to be associated with prevalences of enteric fever. We by no means wish to suggest a limit to the operation of meteorological conditions by explaining away any direct influence they may have upon disease; but merely to indicate that, with the very imperfect knowledge we at present possess on the subject, the study should be approached with all scientific caution. Many of the observations which can be made by officers of health must almost necessarily be limited to comparatively small areas, but when put together they will aid in the solution of a very difficult but most interesting subject. Hitherto not many medical investigators have been attracted to its elucidation, but such reports as the one we are now discussing, and the carefully prepared papers which are from time to time communicated to the Epidemiological Society by Dr. G. B. LONGSTAFF, all tend in the direction indicated.

◆

MRS. GRANT DUFF, the wife of his Excellency the Governor of Madras, has recently presided over a meeting, at Madras, for discussing the establishment of a hospital there for the Hindu and Mahummedan women whose religious feelings and social duties preclude them from seeking the aid of medical men. The speech delivered by MRS. DUFF at this interesting meeting, which seems to have been attended by all the notabilities of the Presidency, native as well as British, abounds in good sense, refined feeling, and the truest appreciation of those silent but potent influences which are most likely to assimilate our great Indian Empire into our own national family. In addition to this matter of good sentiment, in the speech there is much light cast upon the present state of medicine in India. There is, we are told, no institution in Madras to which Gosha women can go without violating their religious feelings. The caste wards of the General and Lying-in Hospitals are under the superintendence of men, and into them a Gosha woman will rarely enter, except as a last resource, and when human aid is no longer of any avail. We are also informed that the greatest suffering, ending sometimes in death, is caused by unskilled and unqualified female practitioners throughout India.

To meet these two difficulties the new institution is started. The original conception of it is due to Surgeon-General CORNISH, who, with his usual happy facility for foreseeing great results from unpretending projects, when they are set in the mind of the world in the right way, called the attention of the Government to the subject last year, and led the Government to determine that, so soon as the natives expressed a strong desire to have the suggestion carried into practice, it would give its support. That expression, led off by a native gentleman, Mr. RAMASAWENEY, having come "in a very liberal form," the initiatory stages of the project may be considered as over, and the prospect of the existence of a great and useful institution is fairly in view. The work intended to be carried out at the hospital will be the teaching of the practice of medicine by the European methods, with all the resources of modern science; the selection as teachers and practitioners of none but those whose status is of competent worth; the performance of important surgical operations which cannot at present be done from the want of a suitably fitted up hospital; and the introduction of the necessary requirements for a school where diseases of the eye, and other diseases requiring particular and advanced skill for their successful treatment, can be combated. The hospital—as Mr. AIGER, one of the prominent supporters of the movement, explained—will be under the superintendence of a lady, who will induce lady patients to visit it; "and thus, while the scientific system of dealing with disease will be adopted, the ignorant practitioners will be gradually cleared away." It is intended for the present to have from twenty to twenty-five beds for in-patients, to increase the number as the demand for accommodation extends, and to have consulting-rooms for caste and Gosha women. The QUEEN-EMPRESS is to be asked to be patroness; her Excellency, Mrs. GRANT DUFF, vice-patroness; and native ladies throughout the Presidency are to be solicited to give their countenance and support, and a considerable amount of money has already been subscribed. In the new design the scope for the kind of labour very suitable for women is of the widest; and if something like it were instituted in all our dependencies, where native habits have to be conciliated, so much the sounder would be the union between the centre of power and the radius of it.

Annotations.

"Ne quid nimis."

THE ARMY MEDICAL SERVICE IN THE SOUDAN.

IN the discussion last week on the vote in the Army Estimates for medical establishments, the question of the relation of the National Aid Society to the Army Medical Department was brought under notice by Dr. Farquharson. The statements which have from time to time been made as to the benefits conferred upon the army by the Society and the inferences which have been drawn as to the inefficiency of the Medical Service, if it required, in the interests of the soldier, to be supplemented by this voluntary and irresponsible aid, certainly seemed to call for some explanation. Dr. Farquharson, therefore, without wishing to undervalue any service the Society might have had it in its power to perform, asked who was responsible for the care of the sick and wounded, and whether there was any deficiency in the supplies of necessaries and even of superfluities furnished by the Army Medical Department. The financial Under-Secretary for War, while claiming for the National Aid Society that it was doing good work in Egypt, distinctly laid down the principle that the Army Medical Department was "not only primarily but entirely responsible for the care of the sick and wounded, but this responsibility did not impair the recognition of the generous and charitable aid rendered by the Society." We still hold strongly to the opinion that as the Government is bound to provide all that may be requisite for the sick and wounded soldier, and has in the present campaign made abundant and liberal provision for all their wants, the operations of the National Aid Society would have been much more deserving of praise had they been directed in favour of the wives and children and of the widows and orphans of the soldiers, for whom no adequate provision is made by the Government. We have considerable doubts as to the benefits conferred by the present working of the Society; we have none as to the claims of the widows and orphans upon the kindness and benevolence of those who have it in their power to aid them. It is very satisfactory to find that there has not been the slightest complaint of any shortcoming on the part of the medical staff, either as regards personal service or the requisite supplies, and in the absence of such default it is difficult to understand how the expenditure incurred in supplementing that which is already sufficient can be justified.

THE NEW BRITISH PHARMACOPŒIA.

On Thursday afternoon the Pharmacopœia Committee, through its chairman, Dr. Quain, were able to report the virtual completion of the new Pharmacopœia and to place a copy on the table. Much satisfaction was expressed with the work, and high praise accorded to Dr. Quain and to the editors of the work, Professors Redwood, Bentley, and Attfield, for the way in which they have performed their respective duties. The revised Pharmacopœia contains over 100 pages of new matter and over 100 new articles, including coca, jaborandi, apomorphine, boric acid, thymol, menthol, iodoform, &c. The volume will be sent to the members of the Council for their suggestions. After these have been discussed and disposed of by the Pharmacopœia Committee, this committee will forward the work to the Executive Committee for publication.

THE ARMY IN THE SOUDAN.

The public have at length received from the Ministry an indication of the course which they mean to take with reference to the troops now serving in the Soudan. Three courses appeared to be available as regards the army in the interior; to maintain their present position, or to concentrate at Dongola and places below Dongola, or to revert to the line of Wady Halfa or Assouan as the effective frontier of Egypt and withdraw the troops as soon as possible from the advanced positions now occupied. The Government has decided to adopt the third course as soon as the rise of the Nile, which is expected to begin in about three weeks, shall enable the movement of the troops and stores to be effected. Lord Hartington stated that the troops at present are fairly protected by huts or other temporary cover, and that although the heat is very great, and the inconvenience and suffering they have to undergo are very considerable, their health has not materially suffered. This change, when effected, will enable the authorities to withdraw a considerable portion of the 9000 men now occupying the posts in the interior. With regard to the force at Sawakin, the Ministers do not seem yet to have been able to make up their minds as to what they mean to do. They have given up the idea of carrying on to Berber the railway recently begun, but to what extent they will remove the troops, or what provision they will make for their maintenance at Sawakin appears to be still among the problems which our rulers find themselves unable to solve. The fears which we have expressed as regards the health of the troops at Sawakin seem to be entertained also by Lord Wolseley, for Lord Hartington stated that "he anticipated that if that force is retained there for a considerable time during the hot weather, it may materially suffer in health." But Ministers desire to suspend their judgment as to the course they ought to pursue until they receive further information. The indecision and delay which have characterised the whole of the proceedings with regard to the Soudan appear still to mark the policy of the Government. It is impossible to read Lord Hartington's speech without asking for what purpose has all this expenditure of life and money been made? The thousands of lives which have been sacrificed, the millions of money which have been thrown into the Nile, or wasted in the desert, have produced nothing but sorrow and shame. The events of the last twelve months in the Soudan must ever form a subject of bitter regret and lamentation to every right-thinking Englishman.

EXCISION OF CEREBRAL TUMOURS.

The unusual interest which characterised the proceedings of the Royal Medical and Chirurgical Society on Tuesday last was due to the reading of a paper on the now famous case which has already occupied attention both in the profession and outside it. We have called the case a famous one, because we are of opinion that it will prove to be the first of a long line of more complete successes. That this opinion is not one of exaggerated hope will be admitted by those who are most competent to judge as well as by those whose reason is not clouded by prejudice. It is singularly unfortunate that one of those accidents which not unfrequently mar the most brilliant surgical successes should have arisen in the case in question. That the patient owed his death to an avoidable accident will be readily conceded if it be remembered that there are now on record —and Dr. Macewen added others at the discussion—cases of surgical interference with the brain far more extensive than the operation performed by Mr. Godlee; so that the special merit of the case recorded by Dr. Hughes Bennett merely lies in this. It was a triumph of medical diagnosis; the symptoms alone revealed the growth, which, unless removed, would have proved fatal. There was nothing very remarkable in the surgery of the case, and nothing special about the nature of the tumour. The chief interest was a medical one; and in this connexion we draw attention to the valuable clinical observations of Dr. Hughlings Jackson, which may be read in our report of the proceedings. As was to be expected, the discussion took a surgical aspect, and there is no question that, as Dr. Ferrier remarked, cerebral surgery is still in its infancy. One of the points which future experience must decide is as to the relative value of closing the wound permanently or treating it by free drainage. Experiments on animals and operations on man show that a large effusion of serum is the necessary accompaniment of operations on the brain. Dr. Ferrier and Mr. Horsley, from their experience with monkeys, believe that a permanent closure of the wound at the end of the operation is the right course to adopt. Mr. Godlee, Dr. Macewen, and Mr. Davy appear to hold the opposite view. For them this large effusion of serum and blood constitutes a source of danger chiefly from the tension which it sets up, and which may lead to opening up of the wound, or to worse effects on the brain. Mr. Godlee and Dr. Macewen used the drainage-tube, and Mr. Davy his open-air method of treatment. Another practical surgical point is the mode of dealing with the parenchymatous bleeding from the wounded brain; all authorities recognise the "welling up" of blood in a wound made in the healthy brain. Gliomata are frequently of a very vascular nature, and the occurrence *of spontaneous hæmorrhage into their substance is a frequent accident.* The hæmorrhage during Mr. Godlee's operation was evidently very great, and *it is possible that* the nature of the tumour may partly account for this. However this may be, it is obvious that one of the surgeon's difficulties is the treatment of the hæmorrhage, and the treatment which Mr. Horsley has successfully employed in monkeys—the hypodermic injection of morphia—is worthy of trial in man. Dr. Macewen took exception to the use of the galvano-cautery as a hæmostatic, *on the ground that* by causing much irritation it favoured the production of *hernia cerebri. This must, we think, be a moot point.* There are other surgical points—such as the question of the reimplantation of the trephined bone, the best kind of antiseptic dressings, the mode of dealing with diffuse growths, and the like—which we cannot enter upon now, and which must remain more or less *open questions.*

THE UNIVERSITY OF LONDON.

The annual general meeting of *Convocation of the University* of London was held on the 12th inst. The first business was the election of Chairman of Convocation in the room of Dr. Storrar, who retires. The only candidate for the *appointment* was Mr. Frederic John Wood, LL.D., who was accordingly elected. In support of a vote of thanks to Dr. Storrar for his services during the past twenty-one years, Mr. Wood reviewed the history of the University since 1848, and the part taken by Dr. Storrar in the contest with the medical authorities at a time when the degrees conferred by the University were not recognised. Dr. Storrar, he concluded, had been the true, noble, and *self-devoting* friend of the University. The resolution was unanimously adopted. The question of the matriculation examination, and a resolution affirming that the principle of allowing candidates who have failed *only in one* subject to come up for examination again in that subject is worthy of acceptance by Convocation and the Senate, were referred to the Annual Committee, and the House was shortly afterwards counted out. The ceremony of the presentation of diplomas, exhibitions, scholarships, medals, and prizes to undergraduates and graduates of the University took place on the 13th inst., in the presence of a large assembly.

"WHY NOT EAT INSECTS?"

A great divine has told us that the maxim of *creation* is "Let us prey." We are not, however, prepared to carry this principle so far into practice as to rob the poor birds of their food. Beyond question insects were made for birds to eat; or, to put the fact in another form, birds were intended to eat insects. Man may eat birds, but not birds' food. Mr. Vincent Holt—who for some mysterious reason has set himself to convince mankind that, as we are hereafter to be preyed upon by the worms, we ought to "take it out" of the worms while we can—argues colloquially thus: "Them insects eats up every blessed green thing that do grow and us farmers starves. Well, eat *them*, and grow fat." We prefer a more *logical and* comprehensive policy, and as the insects eat the green things, and the birds eat the insects, we will eat *the* birds. It would not simply be cruel *to the* birds, but *flying in the* face of nature, to interpose between them *and their* food; more particularly as by passing through their bodies and becoming birds' flesh insects are brought *nearer* to our own standard of tissue. If Mr. Holt will only sit down for five minutes and think the question out in its economic as well as its dietetic bearings, he will agree with us that the course of conduct he prescribes would be as irrational as taking to eating grass ourselves instead of feeding on that delicacy by proxy, and afterwards eating our agents in the shape of mutton and beef. If the principle on which Mr. Holt reasons were carried out to the bitter end, there would be an end of *intermediates altogether,* and we should take to living on carbon, oxygen, hydrogen, and nitrogen, with a little sulphur, instead of boiled eggs, for breakfast, which, to say the least, would be both disagreeable and inconvenient. If anything could possibly induce us to eat insects, it would be Mr. Holt's elegant *brochure,* got up with persuasive taste by Messrs. Field and Tuer; but we decline. "Why not eat insects?" *Because the idea of devouring slugs, spiders, and centipedes,* not to mention other more horrorful monstrosities of the edible insect class, is revolting. Life would not be worth living at the price. In dire straits of famine men and women may bring themselves to devour rats and mice and slugs and caterpillars; nay, in such a state of matters, these creatures might come to be considered delicacies. But there is not the least reason why we should, in pure wilfulness, take to filth as food while clean things that do not creep are to be obtained. *Therefore* we say if "*these insects eats* up every blessed green thing that do grow and us farmers starves," let "us farmers" be a little less hard on the birds, and then, instead of being compelled to eat the insects, the birds will do that for them, and they can eat the birds.

PNEUMOTHORAX FOR HÆMOPTYSIS.

At the last meeting of the Clinical Society Dr. Cayley read a paper on a case of profuse hæmoptysis in which he had artificially induced pneumothorax with the express purpose of arresting the hæmorrhage. We refer our readers to our report for the particulars of the case. The question which we have to discuss here is as to the wisdom and propriety of the procedure which Dr. Cayley so boldly adopted. It is well known that hæmoptysis is not seldom fatal in and of itself; it is also familiar to clinical physicians that hæmoptysis which threatens to prove fatal does not unfrequently become arrested by natural processes. Clinical knowledge can at present carry us no further. That the induction of pneumothorax should be a powerful remedy for checking hæmoptysis rests upon sound physiological data. By inducing pneumothorax the lung is placed *hors de combat,* its circulation is reduced to a minimum, its aspirating power on its contents is done away with, and the lung is reduced to the state of atelectasis of a fœtal lung. So that there is abundant physiological justification for Dr. Cayley's procedure. The presence of air in the pleural cavity cannot be regarded as a very dangerous condition, especially if the air be filtered so as to deprive it of its suspended organic particles, and in this connexion the suggestion made by Mr. R. W. Parker in the discussion which followed Dr. Cayley's paper is worthy of special attention. But, again, the sudden induction of pneumothorax may in virtue of its suddenness be attended with such a physiological displacement or disarrangement of natural *processes as to* place the patient's life in jeopardy. Another consideration which must play a part in *coming to a decision as* to whether pneumothorax should be brought about or not is the *question of the state of the lung,* and *this* is a very wide subject. If the lung be the seat of extensive adhesions or of extensive consolidation of no matter what kind, it is obvious that pneumothorax could not be induced, or induced so partially that the necessary arrest of the circulation through the lung would be impossible. Indeed, on reflection, it will be perceived that the class of cases in which the treatment is likely to prove efficient is a limited one. It is probable that in cases of chronic phthisis limited to the apex of the lung, where the profuse hæmoptysis is the result of rupture of an aneurysm, the induction of pneumothorax would cause the circulation to be reduced to such a *low* ebb that the hæmorrhage would be arrested. However, it is almost futile, *in the absence of data, to* pursue the subject further. The operative treatment followed out by Dr. Cayley will probably not frequently come under consideration; but it must be acknowledged that until we know something more of its practical application the question of its judiciousness must remain in abeyance.

SUCCESSFUL ŒSOPHAGOTOMY FOR REMOVAL OF A HALFPENNY SWALLOWED THREE YEARS PREVIOUSLY.

A BOY seven years of age, now in the Queen's Hospital, Birmingham, has a history rarely paralleled in the annals of operative measures for the removal of foreign bodies. The patient was admitted under the care of Dr. Suckling for asthma, for which he had been unavailingly treated. The history was elicited that a halfpenny had been swallowed three years previously, and that dysphagia and dyspnœa followed immediately afterwards. No attempt at extraction was made, and the incident appears to have been forgotten. On admission the child presented all the appearances of chronic starvation, and only the smallest quantity of liquid could be swallowed, the greater portion of which regurgitated. To solids of any kind the passage was impermeable. Dyspnœa was constant, with paroxysmal cough, copious expectoration, and deficient respiration on the right side. The case having been transferred to Mr. Bennett May, that gentleman found the œsophagus impermeable to anything but the smallest bougies at a point beyond the top of the sternum, but all attempts at detection or removal of the cause were fruitless. On the 25th ult. Mr. May opened the œsophagus low in the neck, and, having passed the finger down it, was able to feel a metallic edge through the wall of the tube. The coin lay in front of the œsophagus, apparently between it and the trachea or the right bronchus. As no point of communication could be discovered, a second incision was made in the œsophagus, and through it the halfpenny was with some difficulty withdrawn. A free escape of air from the wound indicated the existence of a communication between the tubes. The subsequent nutrition of the child has presented considerable difficulty, the fluids swallowed regurgitating through the wound. The patient is now fed three times daily by injecting into the stomach through an elastic catheter half an ounce of brandy and an egg beaten up in half a pint of new milk. On the sixteenth day after the operation the child was sitting up in bed, talking cheerfully. He sleeps well, the bowels act twice daily, and the steady improvement in health augurs complete recovery.

"NO DOCTORS AMONG THE PEERS."

WHO was the witty Premier who declined to make an eminent physician a peer because he would not have as an equal in rank any man upon whom he could call for what he was pleased to represent as menial services? The commotion was great in the House of Lords a few afternoons ago when a noble member fell down in a quite ordinary "fit," and when the *reductio ad absurdum* of etiquette was reached, the House being hastily adjourned to admit of the entrance of a couple of commoners to minister to the needs of the sick peer, and when the members of that august assembly were so generally scared that only one peer, the Earl Spencer, had the presence of mind to hurry to the Commons for medical assistance. We do not, of course, intend to imply that members of the medical profession ought to be introduced into that assembly for the sake of having a doctor in attendance; but it is amusing to note how dire is the panic when human nature comes to face, or to be seen facing, death without medical assistance. We are not of those who think the medical profession stands in urgent need of such Royal countenance as would be involved in bedecking one of its members with a coronet. If Art is the better for being patronised, Science can stand alone, and will not languish for the smile fashion withholds from its professors. All the same, the custom so long honoured by a laborious breach of good manners is very crabbed and wondrously weak.

DEATH FROM HYDROPHOBIA.

LAST week Dr. Diplock, coroner for West Middlesex, held an inquest on the body of a journeyman blacksmith, aged twenty-three, who died, according to Dr. Ferris of Uxbridge, with all the symptoms of hydrophobia. The history showed that there was a possible bite from a dog two years previously, but there seems to be some doubt on this point. If the case were one of rabies, the period of incubation was even for rabies, rather long. Seeing that the case is not perfectly clear, it is allowable to speculate on its nature. Now, Dr. Broadbent and others have placed on record cases which have been characterised by all the symptoms of hydrophobia, which were certainly not due to the usual cause of hydrophobia—i.e., the bite of a rabid animal. In the cases in question there would seem to have been a decided history of terror, almost amounting to mania. This terror, or extreme fright, may have been an efficient cause in bringing about those nervous symptoms which are the chief features of rabies, or the terror may have been one of the symptoms of the nervous disease, however originated. The chief symptoms of rabies may be explained on the view of an extremely irritable state of the grey matter of the spinal cord, medulla oblongata, and adjacent parts. This irritable state of an important part of the cerebral nervous system need not always be due to the action of the virus of rabies. Other conditions may bring it about, and some authorities have asserted that acute poisoning by alcohol, and perhaps other substances, may give rise to the same condition. It is possible that the case on which the inquest was recently held was one of this abnormal class.

DEFECTIVE SUPERVISION IN SCHOOLS.

ANOTHER very painful case of death in a schoolboy is reported from Darlington. The very temperate statement of the father of the little boy is given as follows by the *Leeds Mercury*:—

"Mr. David Davison, of Lieben Lodge, Darlington, father of the deceased, was examined, and stated that his son was a healthy boy, and had never been seriously ill previously in his life. On the 23rd ult. deceased came home and said he had been ill-treated by the boys of the fifth and sixth forms, who were from fifteen to seventeen years of age, while his boy was ten years of age. He could not sleep, and complained of his knee being lame and being unable to kneel. He went to school, however, on the 24th, and returned at noon in an exhausted state, complaining of pain in his right leg. He called in Dr. M'Carthy and Dr. Gibb, of Newcastle, but the boy lingered, and died on May 7th. He said that the boys had pulled him down and dragged him about. He said they had done so every day, inside and outside school, wherever they had a chance."

Dr. M'Carthy testified to the existence of inflammation in the knee, and of inflammatory fever. He considered them due to such injuries as the boy described to him and Dr. Gibb as having been suffered. The medical witness was interrupted in giving evidence as to the boy's account of what happened. And the coroner seems to have supported the objection made by a solicitor representing one of the boys of the school. The verdict of the jury was as follows: "They were unanimously of opinion that death was caused by accident, but there was not sufficient evidence to show how." They added that they thought a little more guardianship might be exercised over the boys out of school, though they did not by this convey an imputation against any person. We shall be deeply disappointed if this inadequate verdict is to end the inquiry into this case.

THE INFLUENCE OF SEA-VOYAGING UPON THE GENITO-UTERINE FUNCTIONS.

DR. IRWIN of New York, who has had much experience as a ship-surgeon, finds from observations on 451 women that sea-voyages have very marked influences on the uterine functions, producing emmenagogue and rarely the contrary effects; but amenorrhœa often follows landing after a voyage. Habitual discomforts in menstruation are aggravated, and dysmenorrhœa is the commonest complaint, next to sea-sickness, for which the ship-surgeon is consulted. A sea-voyage is also said to produce aphrodisiac effects on both sexes, but the author thinks that high living, idleness, and the close association of the sexes should be discounted in weighing this effect. Abortion and premature labour, when they occur, are probably due to sea-sickness. Besides acting as an emmenagogue, sea-voyages produce tonic, alterative, and sedative results, and are useful in chlorosis, retarded sexual maturity, uterine debility, sterility, and threatened phthisis.

A RUSSIAN MANUAL OF LARYNGOLOGY.

DR. W. N. NIKITIN has recently published a "Handbook of Laryngoscopy and Diseases of the Larynx" in Russian, the first book on the subject that has appeared in that language. He employs sponges for making applications to the larynx, though he adds that dossils of cotton-wool are more convenient, but, apparently, is prevented from using them by his fear of their becoming detached and falling into the trachea. He uses the term "croup" in an anatomical sense, and speaks of croup of the pharynx, and, according to the *St. Petersburg. Med. Woch.*, a confusion of terms is thus produced which is to be regretted. The same paper thinks that the author would have done more service for Russian medicine if he had translated one of the numerous valuable manuals which already exist in other languages than by his own original work.

A MEDICAL MAN CENSURED.

AT an inquest recently held at the Royal South Hants Infirmary, Southampton, touching the death of a boy named John Arnold, aged thirteen, a very important question arose as to the duties of a charity medical officer. It appears that the deceased injured his finger in a chaffcutter on Thursday, April 2nd, and that on the same day he was seen by Mr. Hutchinson, who advised as to the treatment and ordered the patient to come to him again on the following Saturday. By that time the wound was found to have taken on unhealthy action, which in the course of two days developed into gangrene of the little finger, calling for amputation. Mr. Hutchinson very wisely declined to administer an anæsthetic and perform the operation himself; and, as his partner was ill, he determined to send the case to the infirmary. After the removal of the finger matters went on satisfactorily for a week, but at the end of that time tetanus supervened, and from this complication death ensued six days later. Mr. Matthey, assistant-surgeon to the infirmary, deposed that "if the finger had been amputated earlier a source of irritation would have been removed, and the lad would have had a better chance." This may or may not have been the event, but Mr. Matthey's opinion seems to have been based on the assumption that tetanus is due to irritation of the nerves in a wound, whereas the balance of evidence strongly supports the rival theory of blood infection. No doubt when gangrene has developed and its probable extent is indicated, the sooner the necrosed part is removed the better. At the same time it must be admitted out of simple justice to Mr. Hutchinson that he acted with reasonable discretion in waiting as he did before condemning the injured finger, considering the great vascularity of the parts and the high reparative power of the tissues in youth. It is very easy to find fault with a line of treatment that has failed, and to censure a medical man who has had the misfortune to lose his patient. In Mr. Hutchinson's case, however, we see neither carelessness nor wilful neglect of duty. A slight error of judgment there may have been; but surely this scarcely warranted the rider to the verdict of the jury that "Mr. Hutchinson was censurable in sending the case to the infirmary before first trying to obtain some local medical man to assist him in the operation which required to be performed." Had the patient died whilst under that gentleman's care, it is just possible that blame might have been imputed to the doctor for not availing himself of the resources which a hospital affords. The case is an interesting one, and, we doubt not, will be instructive to medical men holding union appointments.

SURGERY AND ROSE-COLOURED URINARY PIGMENTS.

THE urine of patients who have sustained injuries, or who have been submitted to surgical operations, sometimes exhibits a rose-coloured deposit which adheres to the glass vase, can be easily recognised with the naked eye, and is composed of a peculiar material. M. Verneuil is the author of the above statement (*La France Médicale* of May 2nd). This phenomenon accompanies the concentrated urine which follows injuries. It shows itself soon after the accident, is transient, and lasts from one to three days. It is related in some way to disease of the liver, and is especially liable to appear in the urine of alcoholic subjects. The subjects of this rose-coloured deposit are prone to secondary hæmorrhage and gangrene after traumatism. The strain in which M. Verneuil writes is one of novelty. We cannot believe that the "acid rosacique" to which he draws attention is an altogether unfamiliar object. Unless we are greatly in error, there should be nothing novel in the appearance of rose-coloured deposits in the urine of patients the subjects of hepatic disease, even in the absence of injury. Of the nature of the pigment we have yet to learn a great deal. The fact that hepatic disease is a serious complication of wounds has long been recognised. That rose-coloured urinary deposits specially indicate a tendency to secondary hæmorrhage and gangrene of wounds is a proposition which has probably not been hitherto distinctly formulated. We do not altogether fall in with the interpretation of the doctrines that M. Verneuil has brought forward, but we are convinced that the subject is one which will repay renewed attention.

NOT COCAINE.

COCAINE, the wonderful medicament which anæsthetises mucous membranes, and has simplified many minor operations on the eye, is very costly. Hence we must not be surprised to hear that, in Paris at all events, the manufacturers endeavour to obtain as much of the alkaloid as possible by submitting the coca leaves to a second process of exhaustion. The result is very similar to that which follows attempts to make a second infusion out of already exhausted tea leaves. Certain substances are extracted which are not cocaine, but have nevertheless a remarkable effect on the pupil, causing it to dilate in a marked manner. These substances are derivatives of hygrine, most of which are mydriatics. Eserine is not an efficient antagonist to atropine, but it is to these derivatives of hygrine. Our readers may have observed that different observers have made different statements with regard to the action of cocaine on the pupil. Some have asserted that cocaine has a powerful mydriatic effect, which others have not noticed. The explanation appears to be rendered patent by the above-mentioned facts.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the Medico-Psychological Association was held on May 8th, at Bethlem Hospital, Dr. Rayner, President, in the chair. There was a very numerous attendance of members, and the provisions of the new Lunacy Bill were discussed at some length, a very strong expression of opinion being elicited that the intervention of the magisterial authority (as provided in Clause 2) prior to the granting of an order for the treatment of a person of unsound mind, was undesirable, and would lead, if adopted, to delay in treatment, to attempts at evasion of the law, and other untoward results. It was, however, considered difficult to suggest any officials for carrying out the proposed provision other than those indicated in the Bill, but it was urged that the power of those authorities should be purely "ministerial," and that when any doubt arose on medical questions they should only have power to direct a further medical examination. It was reported that these and other points, including the desirability of protection to medical persons signing certificates of insanity, and more extensive provision for secrecy in examination, had been already brought under the notice of the Lord Chancellor by a deputation to his office. A committee was appointed to draw up a suitable resolution to be presented to the annual meeting, in the event of Lord Shaftesbury's resignation of the chairmanship of the Lunacy Commission being confirmed.

HOSPITAL SATURDAY IN BIRMINGHAM.

THE amount contributed to this fund up to the time of going to press was £5860 8*s.* 0*d.*, as against the total of £5410 5*s.* 7*d.* last year. It is expected that when the lists are complete, over £6000 will be realised, the largest amount since the institution of the movement, over thirteen years ago. No less than £489 2*s.* 2*d.* has been contributed by the operatives in three firms, whose names deserve special mention:—Kynoch's, £245 5*s.* 6*d.*; Nettlefold's, £139 2*s.* 8*d.*; Tangye's, £104 14*s.* The employées in the first (cartridge works) are chiefly females, while the third amount only partially represents what Tangye's engineering works have done for their local charities. They have additionally expended £124 16*s.* in the purchase of hospital tickets.

SYPHILIS IN RUSSIA.

HERZENSTEIN has brought out the first part of his work on Medical Geography and Statistics in Russia. This deals with Syphilis. He complains that many of the official statistical records are evidently of little value for scientific purposes; for example, the cases of syphilis in the Wilna government in 1877 were returned as 211 in hospital and 29 in private practice. In 1878 not a single syphilitic recruit was found in Livonia; and in the two years 1879 and 1880, of sixty-three recruits, only one was reported as syphilitic. In 1871, 275,761 working men were examined, and only 194 were found affected—numbers which are all of them obviously too low. He has made use of the best sources of information open to him, and has come to the conclusion that 2,000,000, or 2 per cent., of the inhabitants of Russia are syphilitic, and that of the 13,000,000 families it contains some 700,000 are tainted. The way in which the disease is spread is by peasants, who, leaving the country for the large towns in order either to work in factories or for military service, contract the disease, carrying it back to their villages when they return—whole families thus becoming affected.

NEGLECTED NUISANCES AND TYPHOID.

IF any point in the history of typhoid fever may be held to be established, it is the constant and essential relation which exists between that disease and the presence of sewage impurities. We cannot therefore but strongly condemn the blind neglect of cleanliness in a case which affords us the latest recorded illustration of this truth. The circumstances were the following: An inspector of nuisances at Darlaston was required by the Local Board of Health, at the instance of the medical officer of the Board, to clear away an accumulation of sewage matter at the back of a house in which there were four cases of typhoid fever. The medical officer and the Board in so doing were of course only taking the first essential step in the treatment of disease, the removal of its cause. The inspector, however, had other views. He saw no need for interference, and left matters as they were. Under such conditions no remedies could be expected to effect their purpose, and we are not surprised to learn that out of four persons attacked by the disease three died, an unusually high mortality for enteric fever. It must be evident to all that the censure which this official justly incurred at the hands of his employers is but a light one, unless it implies an assurance that like offences will be prevented in the future.

THE EDINBURGH GRADUATES' CLUB.

THE members of this Club assembled in great force on Wednesday evening at the Holborn Restaurant, under the genial presidency of the distinguished Rector, Sir Stafford Northcote. There were nearly one hundred members present. The Rector was supported on the right by Field Marshall Lord Strathnairn, and on the left by the new Principal of the University, Sir William Muir. There were also present the Lord Provost of Edinburgh, Sir Charles Nicholson, Professor Geikie, Professor Mackie, Dr. Haldane, and Professor Flower.

THE PNEUMONIA COCCUS.

L. BRIEGER has examined the coccus described by Friedländer as the excitant of the croupous form of pneumonia. It was cultivated with success in solutions of grape and cane sugar neutralised with lime, and containing fibrin and nutrient salts. The cultures, even after two months, when injected into the breasts of mice and guinea-pigs produced distinct pleuritic symptoms. The guinea-pigs resisted the effects strongly, few of them dying; their exudations contained cocci and minute rods in their characteristic capsules. There is nothing in the chemical constitution of the cocci to account for their virulent character. The author tried to produce ptomaines from pure cultures, but without success.

SOAP IN BLOOD.

F. HOPPE-SEYLER, in the *Zeit. Physiol. Chem.*, states that a soda soap exists in the serum of blood and of chyle, and that it may be obtained by precipitation with alcohol and subsequent evaporation at a low temperature. Blood serum of the ox, horse, and dog contains 0·05 to 0·12 per cent. of the fatty acids of soap; human chyle 0·23 per cent. of soap and 0·723 of fat. Blood serum in a case of pneumonia contained 0·662 fatty acids of soap. The origin of soap in these fluids has not as yet been accounted for.

NITRITE OF AMYL IN SOUTH-AMERICAN INTERMITTENT FEVERS.

IN a paper on nitrite of amyl in *El Ensayo Médico* of Caracas, Don José Gomez Rosende says that in intermittent fevers, if administered in the first stage, it certainly stops the cold stage, and that when the hot stage comes on, followed by sweating, it brings the pyrexia to an end. It is, however, by no means to be looked upon as a specific or as a substitute for quinine, though it has the power of controlling the most distressing symptoms of these fevers.

THE TEETH IN MORPHIOMANIA.

As the result of a careful investigation, M. Combes has arrived at the conclusion that the chronic ingestion of morphia leads to rapid decay of the teeth. The disease appears first in the enamel of the teeth, and the large molars are the first to be affected; the small molars are next diseased; then the incisors suffer, and last of all the canines. As the enamel is insensitive, and as there is no periostitis, the disease makes rapid progress without causing much pain. The effect of morphia on the sensory nerves should also be borne in mind. The hair falls off at the same time that the teeth decay in morphiomaniacs.

THE SANITARY CONFERENCE.

FRANCE will be represented at the International Sanitary Conference at Rome by Drs. Brouardel, Proust, and Rochard; and Abbate Pasha, an Italian physician on the Khedive's staff, has been selected to represent the Egyptian Government.

SIR WILLIAM JENNER.

WE are happy to announce that Sir William Jenner has quite recovered from his attack, and has gone to the seaside for a fortnight.

DESPATCHES from Sawakin announce that at the H Redoubt there are now in hospital 169 non-commissioned officers and men. The total number of deaths have been 13. Up to the 6th inst. there had been 83 cases of dysentery and 27 of enteric fever admitted. At the auxiliary hospital on Quarantine Island Surgeon Major Corry had on the 6th inst. 97 non-commissioned officers and men, 18 of whom were suffering from dysentery and diarrhœa and 12 from fevers. The hospital consists of four well-ventilated wooden huts with a capacity for 100 beds.

DR. G. H. R. DABBS, medical officer of health for Shanklin, Isle of Wight, has, in his report for 1884, expressed his willingness to advise, unofficially, local builders on any points connected with sanitary arrangements of new houses or the alterations of existing systems. Dr. Dabbs' example in this respect might, we think, be usefully followed in other districts.

THE Royal Academy of Medicine of Rome has addressed a letter of thanks to Prince Alexander Torlonia for his munificent present to the city of a surgical amphitheatre and thirty beds, completely equipped. Professor Mazzoni, lately deceased, was the Prince's adviser in the erection of the institution, which is specially devoted to major surgery.

THE International Board of Health in Constantinople has, with a view to obviate the dangers of infectious disease in case of the outbreak of war, telegraphed to Dr. Jablonowski, who has been commissioned to study the plague on the Persian frontier, to remain there, and if necessary to take the requisite sanitary measures.

SKATOLECARBOXYLIC ACID is said by E. Salkowski, in the *Zeit. Physiol. Chem.*, to form a regular constituent of urine in cases of peritonitis and inflammation of the ileum, and that when present it can be detected with great ease.

THE congress of the French Association for the Advancement of Science will this year be held at Grenoble, the opening of which will take place on the 13th of August next, under the presidency of Professor Verneuil.

DR. SACHARJIN, Professor in the Therapeutical Clinic at Moscow, has given 1200 roubles out of the yearly proceeds of his post to the administrative authority of the university, to be applied to the assistance of poor students.

DR. LEGOUEST, Inspector-General of Military Hospitals, has been placed on the retired list, and is succeeded by Dr. Didiot, Inspector-General attached to the Medical Department of the offices of the Minister of War.

PROFESSOR HYRTL, who from 1847 to 1874 occupied the chair of Anatomy at the University of Vienna, celebrated on March 24th the fiftieth anniversary of his graduation as Doctor of Medicine.

THE Rajah of Sarawak has appointed C. G. R. Storie, M.B., C.M., to be Principal Medical Officer to the Sarawak Government, in place of Dr. E. P. Houghton, retired.

THE Prince of Wales has been pleased to appoint John Lowe, M.D., late of King's Lynn, to be an Honorary Physician to His Royal Highness.

DR. MÜNCH, Professor of Pathological Anatomy in Kieff, has gone to Tashkent, Khiva, and Kokhand for the purpose of studying leprosy.

CHOLERA is stated to have broken out in Rangoon, and the daily return shows an increasing number of deaths.

DR. BURNEY YEO has been appointed Professor of Clinical Therapeutics in King's College, London.

THE eleventh congress of the Italian Medical Association is to be held in Perugia next November.

CHOLERA CONFERENCE AT BERLIN.

IT will be remembered that in July last a conference on cholera was held at Berlin, under the presidency of Professor Virchow, which was opened by an address by Dr. Koch upon his researches in India and Egypt, and was occupied with the discussion of most of the important questions concerning the origin and dissemination of the disease. At the close of the session it was resolved to assemble again in the present year, and last week the meetings were held.[1] In addition to those who took part in the previous conference there were present Herr Koehler, the Director of the Imperial Board of Health, Dr. v. Pettenkofer of Munich, and Dr. Günther of Dresden. The proceedings opened on the 4th inst., the first point for discussion being the experience obtained since the last session upon the cholera bacteria, with especial reference to their durability.

PROFESSOR KOCH, who opened the discussion, referred at first to the accounts published since the last conference. He criticised the statements of Finkler and Prior, Klein and Emmerich, and reaffirmed the fact that the comma bacillus was peculiar to cholera, and was never absent from it. As confirmatory of this, he described the results of his examinations of cover-glass preparations of choleraic intestinal contents sent to him from Calcutta, and showed that the cultures of the comma bacillus obtained from France, Italy, and Germany were absolutely identical. He considered it proved that the comma bacillus occurs exclusively in cholera, that it is readily distinguished from other bacteria, and therefore of diagnostic value. He has performed a large number of experiments upon guinea-pigs, which were given five cubic centimetres of a 5 per cent. soda solution, followed in twenty minutes by an injection into the stomach of ten cubic centimetres of broth containing comma bacilli; laudanum was injected into the abdominal cavity immediately afterwards; the animals remained narcotised for about an hour, and then completely recovered. On the following day they appeared ill, their coats became rough, they became very feeble, and died in from one to three days. The small intestine was found to be swollen, and, together with the stomach and cæcum, was filled with an alkaline, colourless, flaky fluid, which contained a pure culture of comma bacilli. The use of the soda solution and opium had been found to render the animals more susceptible to the pathogenic action of bacteria generally; and the same experiments, although in smaller degrees, succeeded with Finkler's and Denecke's bacillus. But in these latter experiments other phenomena were present—e.g., the Finkler bacillus caused putrefaction, as the odour of the intestinal contents proved. It was found that the administration of large doses of calomel or the use of naphthaline prolonged the life of the inoculated animal for about a day. The comma bacillus is readily destroyed by drying, and by certain disinfectant agents—e.g., carbolic acid in a half per cent. solution. That the human being could be infected was proved by one of the 150 medical men who attended the course at the Hygienic Institute becoming attacked with cholerine. Comma bacilli were found in the dejecta from this case, and pure cultivations were made. Experiments were also made to determine the durability of the comma bacillus in various media; this was found to be thirty days in spring water, seven days in drain water, twenty-four hours in sewer contents, three to four days on damp linen, eighty-one days in the harbour water of Marseilles (Nicati and Rietsch), and 144 days on agar-agar. A permanent form resembling the spores of other bacteria could not be ascertained.

---

[1] See Deutsche Med. Wochenschrift, May 7th, 1885, and Berliner Klinische Wochenschrift, May 11th, 1885.

Professor von Pettenkofer said that he was not convinced; the experiments on animals were very insufficient, and better results had been obtained by Emmerich, who had brought cultures of bacilli to Munich from Naples. The mode of inoculation upon guinea-pigs practised by Koch did not explain how human beings were infected by cholera. He was unable to regard the comma bacillus as the causal agent of cholera, but considered it far more probable that certain conditions were induced by cholera favourable to the development of the comma bacillus. It was a straining of epidemiological experience to regard the comma bacillus as the cause of cholera; for whereas the bacillus is destroyed by dryness, the dry season in Lower Bengal favours cholera. Then the comma bacilli were present only in the intestine, and not in the organs; and it had to be supposed that they caused the production of a powerful poison in the cholera intestine, which has so little power of absorption. Such, however, could not be proved in the experiments conducted at Munich. Cholera does not seem to be a combination of infection and intoxication, but a purely infective disease. The future must decide whether Emmerich's rods are the actual excitants; they are found in organs, as cultivations proved, although not detectible in microscopical sections. Animals infected with them died with vomiting and diarrhœa, as in cholera. But whatever the verdict as to the bacilli, there must first be established a conformity with epidemiological facts. If cholera patients are not directly infected, then the cholera fungus can have no share in inducing the disease; and if cholera is dependent upon conditions of locality and season, then also a cholera fungus cannot determine it.

Dr. B. Fünkel mentioned that the only bacterium of the intestine which had a morphological similarity to the comma bacillus was a comma-shaped vibrio occurring in the mouth. Like many others, he had attempted to cultivate this organism, which Dr. Koch had shown at the second sitting of the previous conference, and he could positively affirm that it does not grow in gelatine media.

Professor Koch, replying to Professor Pettenkofer's arguments, pointed out that the methods employed by Emmerich were open to objection and to error. There was no analogous instance whatever of a bacillus being secondary to a disease with which it was solely associated. The dry season in Calcutta does not make the town dry, but diminishes the rich water-supply of the place. Opposed to the failures at Munich to obtain a poison from pure cultures of the comma bacillus were experiments (not yet concluded) which he was making, giving positive results. Cholera was never, like anthrax and small-pox, disseminated by dry conditions, and experience was opposed to there being a permanent state of the bacillus.

The debate was resumed on the following day (May 5th) by Professor von Pettenkofer, who pointed out that many facts were unexplained by the doctrine that the comma bacillus or Emmerich's bacillus was the cause of cholera—e.g., the latency of an epidemic during winter, its recurrence and its acknowledged dependence on time and place. He compared cholera to malaria, which, although communicable by inoculation, still depends upon conditions of soil. A distinction should be made between artificial and natural infection, for it cannot be thought that an epidemic occurs in the same manner as experimental infection.

Professor Virchow said that experiments upon animals were not absolutely necessary. The animals infected by Emmerich's fungus showed phenomena which were readily mistaken for those of cholera, but many substances could excite similar symptoms. Thus, in 1847 he had produced choleriform symptoms and lesions in dogs by the injection of putrid material into the blood; and he was therefore led to compare cholera with putrid infection, not however considering them to be identical. In Koch's experiments the opium may have prevented diarrhœa and vomiting, and therefore the experiments were in a sense defective, and would have to be repeated. Emmerich, by cultivating his bacilli in blood from a living vein may have obtained an accidental form. The constant occurrence of Koch's bacillus in the intestine, the special seat of cholera, was in favour of his view. The gastric secretion is not invariably acid, and therefore dyspeptic conditions might render a previous preparation of the animals superfluous. In these diseases—as muscardine or the potato disease, the fungoid nature of which had long been known—it was still a question why an epidemic arises and why it disappears. In spite of the knowledge gained respecting morbific fungi, but little progress had been made in explaining the cause of epidemics. Although the comma bacillus had no permanent form, yet it had a certain duration of life, for Dr. Babes had found cultures to retain their viability at the end of six months, and had procured a specially large form of vegetation composed of broad, longitudinally striated spirilla that was very durable; it was produced by exposure to low temperatures, but could readily develop into short comma-shaped forms. But the form of the bacillus varies with varying external conditions. The vesicular forms of Ferran, described as evolved from the spirilla, are degenerate and sterile. The prolongation of epidemics from year to year is sufficiently explained by the duration of life of the bacillus; and in other directions the discovery of this organism was a positive gain to knowledge. It was not opposed to former experience, especially that derived from the meritorious labours of von Pettenkofer; but too profound a penetration into theoretical speculations must be avoided.

Professor Hirsch remarked that epidemiological inquiry was at least of as much importance as bacteriology in reference to the course of epidemics and to prophylaxis.

Drs. Koch, Pistor, von Pettenkofer, and Virchow made some further observations on the point; and the Conference next discussed the question of the spread of cholera by human intercourse, pilgrimages, and by ships. This was opened by Professor Koch, who instanced the spread of cholera in India by pilgrimages, gave examples of ship epidemics of long duration, and showed how unreliable were the accounts given by sailors.

Professor von Pettenkofer assigned little importance to pilgrimages and railway intercourse, and urged caution in accepting statements of the transmission of cholera by travellers. At this point the debate was adjourned, a demonstration being given of guinea-pigs (living and dead) infected with comma bacilli.

At the third sitting on May 6th, the debate on the second point was resumed, together with that on the third—viz., the influence of soil, air, and water.

Dr. GÜNTHER of Dresden adduced evidence from Saxony to show that human intercourse does not suffice to disseminate cholera at all times and under all circumstances, but that a seasonal and local disposition is necessary for the occurrence of an epidemic.

Professor HIRSCH remarked that human intercourse did not invariably determine the spread of cholera, but that cholera is always spread through human intercourse.

Professor KOCH, alluding to the demonstration of the previous day, said that of fourteen guinea-pigs inoculated on the 4th inst. only two had survived, and suggested that, as with other plants, the cholera fungus may find temporarily conditions favourable to its existence, afterwards perishing for lack of these conditions. He cited instances in proof of an acquired immunity against cholera, and of its spread by pilgrims, travellers, and troops. Proof of such dissemination could not be expected in all instances, but we must be content to establish it indubitably in certain cases. The fact was of the highest importance in view of the prophylactic measures to be taken by authorities. The long duration of cholera on shipboard could not be explained by regarding the soil as the sole condition of its origin, but could be accounted for on the view of transmission from man to man, for the incubation period of cholera is very short.

Dr. GÜNTHER said that the incubation period usually lasted for four days, but he knew of cases where it was from ten to seventeen days.

Dr. MEHLHAUSEN cited instances of the spread of cholera by troops, and Drs. EULENBERG and HIRSCH gave similar examples of its spread by rafts.

Professor von PETTENKOFER did not deny the fact of an acquired personal immunity after an attack, but asserted that it was the local immunity which determined the occurrence of an epidemic. The disposition of a locality for epidemics consists in part of local constant conditions, in part of local transitory (seasonal) factors. He by no means denied the influence of human intercourse in the spread of cholera; but this alone does not suffice to evoke an epidemic. Local and seasonal influences must determine this. He did not know how the infective germ gets on board ship; but the mere shipment of a patient is not sufficient to cause the disease to spread.

Professor VIRCHOW said that the supporters of the contagionist doctrine did not admit that direct transference from man to man must of necessity occur; that is proved by infection through cholera linen, still more by the pure cultures, in which the development and sustenance of cholera germs take place outside the human body. But just as certainly did these cultures show that it is not in the earth where these germs are able to thrive. Up to the present not a single case was known where the existence of cholera germs in the soil had been proved. He would not deny the possibility, but he disputed the exclusiveness of the soil theory. Experiment and observation of separate cases yield more certain conclusions than whole epidemics, which were only considered on a large scale. He had personal knowledge of the transference of cholera from man to man in 1871, and had published a conclusive observation in his collected works. In a prison, which at the time was free from cholera, three men were attacked who had charge of a case of cholera which had been admitted. Cholera was transmitted on board ship which had nothing to do with the soil—e.g., the Stetten Transatlantic steamer *Franklin*. Although no doubt can exist that the spread of cholera is not dependent on a poison or germs arising from the soil, still, what is as yet known of the history of the comma bacillus does not exclude the possibility of its developing and thriving in the soil under certain conditions. He, therefore, saw no difficulty in agreeing with Professor von Pettenkofer provided that he abandoned his exclusive standpoint.

Professor von PETTENKOFER said that originally he accepted contagion as the chief factor, but observation of the varying behaviour of cholera, according to locality and period, obliged him to lay especial stress on the chronological and local factors.

Dr. MEHLHAUSEN related an undoubted instance of communicability of cholera from person to person observed in Thorn in 1873.

(*To be continued.*)

THE ANCIENT AND MODERN METHODS OF TREATING EPIDEMICS OF SMALL-POX IN INDIA.

SURGEON-MAJOR ROBERT PRINGLE, M.D., read a paper on the above subject at the rooms of the Society of Arts on May 8th. He drew attention to the ancient method of treating epidemics of small-pox in India, which was that of inoculation, while the modern, as was to be expected, was Jenner's great discovery of vaccination. The details given by Dr. Pringle of the practice of inoculation in India were the result of continuous personal observation during the past twenty years, in the independent native State of Tirri Ghurwâl, in the Himalayas. Here it would appear that inoculation had been practised from, what might be termed, time immemorial. After giving the details of the operation, Dr. Pringle entered into full particulars of the benefits of this practice. These he described as visible benefits, and compared them with the effects of spontaneous small-pox in the plains at the foot of the Himalayas, where no inoculation was practised, and before vaccination could have made any impression on the adult population. In accounting for the remarkable difference between the visible effects of spontaneous small-pox, as met with in the plains of Hindoostan, and those seen in the cases of inoculated small-pox in the Himalayas, Dr. Pringle remarked that, in his opinion, it would seem to be due, on the part of the inoculators, to what he termed accidental cultivation of the product of the spontaneous small-pox eruption, to a considerable extent on the lines of M. Pasteur's recent discoveries. The process of this accidental small-pox cultivation consisted in the lymph being carried on through many transmissions till the cultivated product resembled in its action cow-pox lymph, and only produced local symptoms at the point of insertion, or else, so rarely a small-pox eruption, as to make its appearance quite exceptional—thus corresponding in a remarkable manner with the common and destructive outbreaks of sheep-pox and the rare and mild cases of cow-pox. In 1864 Dr. Pringle inaugurated the present system of voluntary vaccination in the Mesopotamia of the Ganges and Jumna, from fifty miles above their junction at Allahabad to their sources in the Himalayas. In alluding to this modern prophylactic for small-pox, he confined his remarks to the points in which the practice of vaccination differs in India from that carried on in this country. These he summed up under the head of climatic causes, which, owing to the high temperature met with in the plains of Hindoostan from April to October, limited the practice of vaccination to the cold weather months—viz., from the middle of October to the middle of March. Thus, out of the twelve months, there were only five in which vaccination could be practised; and this led him to describe the means he adopted to keep up the supply of vaccine lymph in the Himalayas, in what he termed "lymph nurseries." Latterly, by retrovaccinating—i.e., vaccinating a calf and taking the lymph from the eruption—Dr. Pringle has succeeded in making his sanitary circle, with its population of ten millions, and other circles of similar extent, independent of any supplies from the National Vaccine Establishment. In comparing the two prophylactic measures, Dr. Pringle pointed out that, while the practice of inoculation no doubt kept up the disease of small-pox, and was dependent on its presence for the virus required for the operation, yet, even imperfectly as it was carried on, it was nevertheless a very great boon to the population, as it could be practised throughout the year. In the practice of inoculation, he said, the repetition of the operation at any future period of life was never thought of, and in this, according to the generally, and indeed latest, received view of vaccination, it was, in his opinion, far superior to vaccination in countries like India. As regards revaccination, Dr. Pringle said had he considered revaccination necessary, he would never have spent twenty years of his life in a continuous effort to supplant inoculation without a repetition of the operation, with vaccination *plus* revaccination after a given number of years. In India at least, and most certainly not in his circle, with its ten millions, where, with two hundred operators working at nothing else but vaccination for five months, he could not reach half the annual birth-rate. He therefore discouraged revaccination in his circle, and made quality the basis of his work and not *quantity*, explaining to his subordinates that if the former imparted the immunity claimed for it this result would quickly be followed by the latter. In concluding, Dr. Pringle illustrated the absolute necessity of carefully supervising any system of vaccination, both as regards the veracity of the returns submitted and the quality of the work, with reference to the knowledge and skill of the operators. In 1863 the vaccination in the second circle in the North-West Provinces was held up as a pattern to India, and yet within twenty years this system in the circle is stigmatised in a public document as a "wholesale fabrication of returns," while that in the first circle in the same report was stated to be such that the magistrate of a large district placed the following on record:—"I regret to record my conviction that these numbers are a wholesale imposition." Yet in twenty years Dr. Pringle's vaccination in this first circle, on the principle of quality, not quantity, was such that it was publicly commended by the Government in 1883, and a Mahomedan gentleman of influence, as the result of the benefits exhibited by this mode of work in his own district, with a population of over one million, brought into and carried through the Council of the Viceroy a Bill for compulsory vaccination in certain localities and under certain conditions. Dr. Pringle from the preceding aimed at showing that the cause of the failure of a system of vaccination, if carefully and fearlessly inquired into, will be found to lie, not in any imaginary deterioration in the vaccine virus, when proper care is taken, nor yet in a diminution in the protective power of really good vaccination by the lapse of years, or in the neglect of revaccination; but to what the Government of the North-West Provinces recorded in 1883, in the case of the second sanitary circle, as *the inexcusable negligence of the supervising officials*, and in many other cases no doubt to the ignorance of the operators and the employment of stored lymph (for which no one seems to be directly responsible), imparting a false protection, the result of a spurious vaccination.

THE INTERNATIONAL SANITARY CONFERENCE.

The Roman papers announce that the Italian Government abstained from drawing up a formal programme for the Sanitary Conference which assembles in Rome to-day (15th inst.), acting on the precedent of the Constantinople Conference, which entrusted a committee selected from among its own members with the task of framing the programme of its labours. However, Signor Mancini, Minister of Foreign Affairs, in a recent circular to the Powers to be represented at the Conference, formulated a summary of the intentions of the Italian Government as to the Conference in question. According to this circular, the Conference is designed to have a twofold purpose—the one technico-scientific, the other diplomatico-administrative. The Roman Conference would be able to examine the findings of the preceding sanitary conferences, notably that of Vienna, in order to see what conclusions are worth maintaining, what are to be modified, what to be suppressed. As for the diplomatico-administrative part, the Conference, examining the question of the preventive measures which may be adopted with due regard to the interests of commerce, and to the freedom of inter-communication, would have to fix the basis of an international accord, which should be acceptable to all the Governments, for extinguishing contagious diseases, while laying down rules, based on uniform principles, as well for quarantine as for any other system of protection. It is understood, however, that the treatment of the negotiations already in progress as to the composition and attributes of the Sanitary Council in Egypt must be reserved and kept separate, the Conference having it in its power to avail itself at an opportune time of the conclusions of that particular transaction. Finally, the Conference might be able to define practical rules for the immediate application of the international system of sanitary directions counselled by the Washington Conference, as well as the mode of establishing in convenient localities an official agency for arriving at accurate sanitary information, and transmitting the same to the Governments forming part of an International Sanitary Union to be constituted according to the attributes and criteria which the Conference should determine. This, however, would have absolute freedom of initiation and of deliberation—in other words, complete liberty of action.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Leicester (Urban).—Dr. Johnson's report upon the health of this borough during 1884 is largely devoted to the consideration of the waste of infant life, which has so long been the prevailing feature of the vital statistics of this town, and which showed an exceptional excess last year. With regard to the present population of the borough, the medical officer is of opinion that the Registrar-General's estimate, based upon the hypothesis that the rate of increase since 1881 has been the same as that which prevailed during the last intercensal period, 1871-81, considerably exceeds the true number. It is pointed out, in support of this opinion, that the births recorded in recent years have shown no increase; indeed, the number in 1884 was somewhat below that in 1880. Dr. Ogle, of the Registrar-General's office, also showed, in a letter which Dr. Johnson prints in his report, that if the rate of increase of population in Leicester since 1881 has been the same as that of inhabited houses on the rate-book, the population in the middle of 1884 was 127,929, and nearly 5000 less than the estimate by the Registrar-General's usual method. Dr. Johnson, in his report, has adopted this lower estimate, which makes the death-rate in the borough last year 22·9, instead of 22·1 as reported by the Registrar-General. This rate shows an increase of 3·7 upon the low rate in 1883, but was slightly below the mean rate in the eight years 1875-82. It may be noted, however, that, while adopting a revised population for 1884, Dr. Johnson has not corrected his rates for recent years, and that the rates given for the five years 1875-79 in Tables I. and IV. differ widely. The death-rate in Leicester last year from the principal zymotic diseases was, according to the Registrar-General, 4·03 per 1000; but it is worthy of note that the mortality from each of these diseases was below the average rate in the twenty-eight towns, except that from diarrhœa, which was more than double the average rate. Dr. Johnson attributes the startling mortality from summer diarrhœa in Leicester to "introduction into the system, by means of air or in food, of living organic ferments derived from the putrefactive decomposition of animal refuse matter retained in many of the town sewers, and present also through soakage in the adjacent subsoil." Infant mortality in Leicester last year, measured by the number of deaths under one year to births registered, was equal to 233 per 1000, against a mean of 168 in the twenty-eight towns. This excess was only in part explained by the marked diarrhœa mortality, as the deaths referred to atrophy, debility, premature birth, and convulsions also showed a marked excess. No health report of a large town or community is complete which does not show the death-rates of males and females at five or more groups of ages, calculated upon the numbers living at the same ages. This information is especially necessary in the case of Leicester, and would help to throw light upon the causes of the high rate of infant mortality from which the town has suffered for so many years. No such information is, however, given in the report before us. Scarlet fever has been more or less fatally prevalent in Leicester during the last five years, and 63 deaths resulted from this cause last year, of which 16 occurred in the Fever Hospital. Dr. Johnson points out that without more general and ready use of the fever hospital accommodation provided by the sanitary authority, success in "clearing the town from this lingering pestilence" is unattainable. Bearing in mind the unsatisfactory condition of the subsoil, and the suggested connexion between this defect and the excessive mortality from diarrhœa, the fact that upwards of 1200 houses in the town still derive their water-supply from surface wells suggests a source of grave danger to the health of the town.

Lincoln Urban District.—A somewhat exhaustive report has been submitted to the Corporation by Dr. C. Harrison, medical officer of health and public analyst, respecting the water-supply of the city. The report sums up in a very clear manner the considerations which should influence a body having charge of the public health, and who supply to the population a water-supply derived from such a source as the river Witham. Dr. Harrison explains that the water after filtration as now supplied contains an excess of organic matter, making it only a second-class water. The sources of the water are polluted by drainage from land highly cultivated and occasionally manured by nightsoil, and he asserts that water from such a source must be dangerous. There are filter beds capable of filtering more than a million gallons daily, but the conclusions arrived at are that the quantity available is not sufficient for the wants of the city, and that it is not advisable that the supply should be taken from the river. Putting aside the unfavourable chemical condition of the water, we certainly concur in Dr. Harrison's opinion that a river receiving drainage and effluent from a large town could not with any degree of safety be used for domestic purposes. Indeed, as he asserts, it is unwise and dangerous to take water from a source known to be polluted or liable to pollution, and then to trust to the purifying effects of filtration to render it safe for consumption.

Wolverhampton Urban District.—During 1884 small-pox became very prevalent in Wolverhampton, and it was found necessary to fit up a house known as Holly Hall as a temporary infectious hospital. Of a total of 37 vaccinated patients, 1 case terminated fatally; whereas of 6 unvaccinated, 4 died. Not a case was known to have occurred in any revaccinated person. The town also suffered severely from measles. So, also, 212 cases of scarlet fever were heard of, and Dr. Malet explains that the efforts to check the spread of this disease were most disheartening. It is a question, however, how far this may have been due to the circumstance that no proper means of isolation are provided for the borough, the sanitary authority still relying on the isolation wards of the General Infirmary for this purpose. Such an arrangement as this has nowhere been found to serve the purposes of a properly organised hospital with its accessories, established and maintained by the sanitary authority. Open middens and cesspits of the worst type still prevail in the borough; underground soft-water tanks, discharging their overflow without disconnexion into the drains, are almost universally resorted to; and in some parts the condition of houses, closets, and courts is such as to merit the term "beastly" in point of filth. A first step towards a remedy has, however, been taken in the investigation and exposure of this state of affairs, and it may be hoped that decided action will soon follow. The deaths included 5 from small-pox, 98 from measles, 37 from scarlet fever, 6 from diphtheria, 21 from non-spasmodic "croup," 12 from continued fever, and 140 from diarrhœa. The general death-rate was 22·2 per 1000.

Isle of Wight Rural District.—In submitting his first annual report on this district, Dr. Groves deals at some length in a description, topographical and geological, of the localities comprised within its area, and he then considers the character of the different water-supplies, especially from the geological point of view. Detailed observations of rainfall and temperature, together with an account of the climate of the island and of the features by which it is influenced, and other matters of extreme interest follow, before the usual sanitary report is commenced. The birth- and death-rates for 1884 were 27·5 and 13·6 per 1000 respectively, and the rate from the principal zymotic diseases was 1·2. Some voluntary notification of infectious diseases is made, and this has sufficed to show the great need of an isolation hospital for sanitary purposes. A cottage is suggested as sufficient to form a nucleus, but probably one of the special pavilions recently designed by the Local Government Board for small localities would better answer the purpose. Plans of these were recently submitted to the Epidemiological Society. The general sanitary circumstances of the rural district, as to water, closets, sewers, drains, piggeries, &c., are next entered into at some length, and it is evident that the island is by no means so free from real danger to health as its many visitors imagine. Rarely, we are told, are the most elementary precautions taken to protect the shallow wells; it is simply a matter of haphazard whether they become polluted or not. Polluted streams and brooks are also resorted to as water-supplies. When Dr. Ballard reported to the Local Government Board some years ago on the state of the island many grave sanitary defects were exposed, but we had hoped that they had before this been remedied. At that time the sanitary organisation was very defective, but it is now evident that, so far as the rural portion of the island is concerned, the authority does not lack a skilled and competent adviser, and we trust that his future reports will show that the sanitary defects he points out will have been removed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5558 births and 3440 deaths were registered during the week ending the 9th inst. The annual death-rate in these towns, which had been equal to 23·4 and 21·1 per 1000 in the preceding two weeks, further declined last week to 20·2, and was lower than in any previous week of this year. During the first five weeks of the current quarter the death-rate in these towns averaged 22·6 per 1000, against 23·5, the mean rate in the corresponding periods of the nine years 1876–84. The lowest rates in these towns last week were 13·0 in Plymouth, 14·1 in Brighton, 15·2 in Bolton, and 15·3 in Hull. The rates in the other towns ranged upwards to 26·4 in Oldham, 26·4 in Blackburn, 28·6 in Preston, and 36·8 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 529 and 449 in the preceding two weeks, were 481 last week; they included 181 from measles, 116 from whooping-cough, 36 from scarlet fever, 37 from "fever," (principally enteric), 33 from diphtheria, 30 from diarrhœa, and 48 from small-pox. No death from any of these principal zymotic diseases was returned last week in Brighton, whereas they caused the highest death-rates in Sunderland, Blackburn, and Newcastle-upon-Tyne. The greatest mortality from measles was recorded in Sunderland, Cardiff, and Newcastle-upon-Tyne; whooping-cough in Preston, Plymouth, and Blackburn; scarlet fever in Sunderland and Salford; and "fever" in Norwich. The 33 deaths from diphtheria in the twenty-eight towns included 24 in London, 3 in Liverpool, and 2 in Oldham. Small-pox caused 71 deaths in London and in its outer ring of suburban districts, 2 in Manchester, 1 in Liverpool, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated on and around London, which had been 1034 and 1282 on the preceding two Saturdays, further rose to 1361 at the end of last week; the admissions, which had been 246 and 354 in the previous two weeks, were 315 last week. The Highgate Small-pox Hospital contained 81 patients on Saturday last, 14 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 512 to 337, further fell last week to 287, and were 75 below the corrected weekly average. The causes of 73, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Newcastle-upon-Tyne, and in eleven other smaller towns. The largest proportions of uncertified deaths occurred in Liverpool, Salford, Oldham, and Bristol.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily declined in the preceding five weeks from 25·0 to 22·4 per 1000, further fell to 20·6 in the week ending May 9th, and was but 0·4 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·9 and 15·7 in Leith and Dundee, to 23·7 in Paisley and 24·3 in Glasgow. The 504 deaths in the eight towns included 25 which were referred to whooping-cough, 13 to measles, 6 to diarrhœa, 5 to diphtheria, 3 to scarlet fever, 3 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 55 deaths resulted from these principal zymotic diseases, against 81 and 64 in the preceding two weeks. These 55 deaths were equal to an annual rate of 2·3 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The deaths from whooping-cough, which had been 30 and 27 in the previous two weeks, further declined to 25 last week, and included 12 in Glasgow and 6 in Edinburgh. The 13 fatal cases of measles also showed a further decline from recent weekly numbers; 11 occurred in Glasgow and 2 in Greenock. Five of the 6 deaths from diarrhœa, 3 of the 5 from diphtheria, and 2 of the 3 from scarlet fever were returned in Glasgow. The 3 deaths referred to "fever" were fewer than in any recent week; 2 occurred in Paisley and 1 in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 131, 118, and 124 in the preceding three weeks, declined to 117 last week, and were 5 below the number returned in the corresponding week of last year. The causes of 79, or 15 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 34·0 and 33·5 per 1000 in the preceding two weeks, further declined to 28·5 in the week ending the 9th inst. During the first five weeks of the current quarter the death-rate in the city averaged 32·4 per 1000, the mean rate during the same period not exceeding 21·3 in London and 18·7 in Edinburgh. The 193 deaths in Dublin last week showed a further decline of 34 from the high numbers in the previous two weeks; they included 12 which were referred to measles, 4 to whooping-cough, 2 to "fever" (typhus, enteric, or simple), 2 to diarrhœa, 1 to scarlet fever, 1 to "fever," and not one to small-pox. These 22 deaths from the principal zymotic diseases showed a decline of 18 from the number in the previous week, and were equal to an annual rate of 3·3 per 1000, the rate from the same diseases last week being 3·1 in London and 1·5 in Edinburgh. The fatal cases of scarlet fever in Dublin, which had been 15 and 17 in the previous two weeks, declined to 12 last week The deaths from scarlet fever, "fever," and diarrhœa also showed a considerable decline. Five inquest cases and 5 deaths from violence were registered last week, and 63, or nearly a third of the deaths, were recorded in public institutions. The deaths of infants showed a marked decline. The causes of 43, or more than 22 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Deputy Surgeon-General George Stewart Watson Ogg, of the Madras Medical Department, principal medical officer of the Hyderabad Subsidiary Force, has been selected for the chief medical charge of the Quetta Field Force.

INDIA OFFICE.—The Queen has approved of the following promotions among the officers of the Staff Corps and Indian Military Forces made by the Government in India:—Deputy Surgeon-General Benjamin Simpson, M.D., of the Bengal Medical Establishment, Deputy Surgeon-General Michael Cudmore Furnell, M.D., of the Madras Medical Establishment, and Deputy Surgeon-General William James Moore, C.I.E., of the Bombay Medical Establishment, to be Surgeons-General. Brigade Surgeon John Brake, of the Bengal Medical Establishment, and Brigade Surgeon John McNeale Donnelly, M.D., of the Madras Medical Establishment, to be Deputy Surgeons-General. Surgeon-Major George Sackville Sutherland, M.D., and Surgeon-Major Emanuel Bonavia, M.D., of the Bengal Medical Establishment, Surgeon-Major William Frederick De Fabeck, M.D., of the Madras Medical Establishment, and Surgeon-Major Edward Harley Raynsford Langley, of the Bombay Medical Establishment, to be Brigade Surgeons.

ADMIRALTY.—The *following appointments have been* made:—Fleet Surgeon John Thomson Comerford, to the *President*, additional; *Fleet Surgeon John S. Dobbyn, M.D.*, to the *Repulse;* Fleet Surgeon James W. Fisher, M.D., to the *Hercules;* Staff Surgeon Solomon Kellett, to the *Rupert;* Surgeon George W. Low, to the *Ganges;* Surgeon Thomas R. Pickthorne, to the *Excellent; and Surgeon James C. Dow, to the Pembroke.*

ARTILLERY VOLUNTEERS.—*1st Renfrew and Dumbarton:* Surgeon William Aitchison Wilson, M.D., is granted the honorary rank of Surgeon-Major; Acting Surgeon James Finlay, M.D., resigns his appointment; William Robert Sewell, *Gent. "Audi alteram partem."

THE TREATMENT OF SEPTICÆMIA BY IRON AND QUININE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 17th last there is the record of a case of septicæmia treated by ammonia and chlorate of potash. The following case I desire to place in contrast.

Mrs. H——, aged twenty-two, was confined on Oct. 15th, 1884, after a very protracted labour of two days' duration. It was her first child, and she was delivered with the forceps. All seemed to go on well until the third day, when the temperature was found to be rising. On the 19th high fever developed, and the discharges were very foul. My directions as regards thorough cleansing of the genitals and injections of Condy's fluid into the vagina (as is my practice after all cases of instrumental labour) had not been *carried out. There was, it should be observed,* a tear of the mucous membrane, about an inch in length, but not very deep, on the posterior wall of the vagina. The evening temperature was 104·8°. I injected Condy's fluid into the fundus, and gave a mixture of steel and quinine every two hours. On the 20th the morning temperature was 101·7°. The fluid was again injected into the fundus, and followed by the injection of carbolic oil (1 to 10). Linen cloths in small pieces, dipped into the oil, were applied to the tear in the vagina, and the external genitals washed thoroughly with carbolic soap by the nurse. I gave directions that the linen rags should be changed three times a day and that the soap should be used every eight hours. Injections were repeated in the evening. On the 21st the morning temperature was 101·9°; evening, 101·7°. The injections of Condy's fluid were continued, but the carbolic oil injection was not used any further. On the 22nd the temperature throughout the day was 100·5°; and the respiration 23. On the 23rd the temperature in the morning was 100·4° and the respiration 22. The medicine was now taken three times a day only. On the 24th the temperature had fallen to 100° in the evening, and the patient expressed a wish to get up, but was ordered to keep her bed for a day or two. On the 25th the temperature in the morning was 99·4°, and fell on the 26th to 98·4°. She was now allowed to get up and go downstairs.

In Mr. Coffin's case, although no doubt the infective material was of a much stronger nature than that developed in this, the recovery seems slow in comparison. The temperature, he states, for six days and a half was over 105°, for nine days over 103°, and for eleven days over 102°. My *patient was cured in seven days,* and my sole object in recording the case is to speak of my theory of the nature of such cases, and the consequent indications as regards treatment, the more especially as Mr. Coffin speaks with considerable reserve in reference to his case.

As regards local treatment, my practice is to purify with Condy's fluid the whole genital tract, and then to inject carbolic oil of the strength of 1 to 10 into the fundus, afterwards applying the same, or else vaseline and iodoform, to any tears in the mucous membrane. The oil I employ as an injection once or twice only, keeping afterwards solely to Condy's fluid in warm water twice a day until the temperature becomes normal, or nearly so. As to constitutional remedies, I consider the arrest of all such septic processes in the blood to be perfectly feasible. Avoiding ammonia, which is a powerful agent for the prevention of the formation of fibrin, and is thus useful (as has been clearly proved) when given to the blood-giver in cases of transfusion, I prescribe astringents and hæmatinics, such as iron and hydrochloric acid, along with germicides, such as quinine and chlorate of potash.

I argue that in puerperal septicæmia we have a disease in which every effort of nature for the prevention of absorption of infective material should be fostered and encouraged. The clots in the maternal sinuses formed on the separation of the placenta may be regarded as the natural barrier to any external morbific influence. The preservation, therefore, of their integrity until they become organised and contracted should be of paramount importance. Hence the advisability of avoiding agents which tend to soften and disperse fibrinous deposits and formations of this nature. Should infection by septic materials have occurred, the efforts of the physician should be directed to strengthen the fortifications raised by natural means, and this can only be effected by astringent and hæmatinic remedies, such as steel and hydrochloric acid, with the assistance of quinine and chlorate of potash, for the destruction of the germs which have found entrance to the circulation by means of the lymphatics. To give "liquefacient" remedies, such as ammonia, sodic salicylate, or potassic iodide, is, I think, simply to break down the natural barrier described, and to further absorption of septic materials by a diffused and weakened circulation—weakened by reason of its deficient fibrin-forming power. Infection of the blood, indeed, is thus doubly ensured by medicinal liquefaction and septic softening of clots, for wherever there is the development of sulphuretted hydrogen by decomposition of animal matter no fibrin can exist. I prescribe five-minim doses of the perchloride of iron, one-grain or two-grain doses of quinine, and five-grain doses of chlorate of potash, with glycerine in half-drachm doses, every two hours, until there is a considerable reduction in the temperature, when I order the mixture to be taken less frequently.

Similarly, I hold that the treatment of enteric fever should be conducted upon an acid and not an alkaline method. I believe I have seen an increased blood heat induced by such a remedy, for instance, as salicylate of soda in this disease, with passive pulmonic congestion, from a condition of over-fluidity thus induced, and quickly removed by the administration of fifteen-minim doses of hydrochloric acid every two hours, and drop doses of steel.

I am, Sir, yours truly,
C. R. ILLINGWORTH, M.D. Edin.
Clayton-le-Moors, March 23rd, 1885.

"TAURO-CHOLATE OF SODA PILLS."

To the Editor of THE LANCET.

SIR,—Please let me add to my little paper which appeared in your issue of the 25th ult., that it is better to use pig's-bile than ox-bile in preparing the tauro-cholate of soda; and that the *bulk* of the glyco-cholate—which is not of any therapeutic value—should be thrown out with acetate of lead, avoiding any excess of the acetate before evaporating the tauro-cholate to the consistency for making into pills. Keratin, easily made from the residue of an ethereal digest of horn shavings by boiling in liquor potassæ, forms the best coating.

I am, Sir, yours truly,
Hanover-square, May 12th, 1885. J. MORTIMER GRANVILLE.

"THE COLLOQUIAL LINGUISTIC FACULTY."

To the Editor of THE LANCET.

SIR,—If I may judge by the considerable extract you have given from Dr. W. H. Walshe's new work, reviewed in the current number of THE LANCET, he has raised the novel and very interesting question, "When may a person properly be said to know a foreign language?" But I fear the tests Dr. Walshe has applied are much too sweeping and exclusive to be of any practical value towards its solution. For instance, a well-known linguist of my acquaintance went for a three weeks' holiday into Wales, without knowing a word of the vernacular, and with no aid towards its acquirement but a pocket dictionary. Yet, by a method of his own and by constant intercourse with the peasantry, he learned the language in the above time—i.e., he was able to converse in it, to read and write it correctly, and knew its formation and grammar. Whether he could understand a Gaiety burlesque in the Welsh tongue I had not thought of asking him.

I know I must not trespass upon your space, but I should just like to submit the following points for Dr. Walshe's consideration. What does he say to the number of our Indian officials who converse and correspond in Hindi, Persian, Pashtú, and other Eastern languages? What to the humble missionaries who translate our Scriptures into such difficult languages as Lithuanian, Finnish, Aramaic, and Coptic, to say nothing of the Kaffre click? A friend of mine, a German cavalry officer, himself a native of Westphalia, has told me he was stationed on one occasion with his regiment at Munich, and that it took him six months to become acquainted with the lingo of his Bavarian servant; yet surely the former must be said to have known German.

On the whole, it seems to me that what marks linguistic power in individuals is an initial faculty of learning language, rather than the degree of actual attainment in any particular form of speech, and the Mezzofanti type is by no means so doubtful as Dr. Walshe appears to think.

I am, Sir, yours truly,
Sussex-gardens, May 12th, 1885. T. FITZPATRICK.

SMALL-POX RISKS.

To the Editor of THE LANCET.

SIR,—I was gratified to find that you call attention to the serious risks run by the unrevaccinated in London during the present widespread epidemic of small-pox, and that you instance the well-known immunity of the servants and nurses of the Highgate Small-pox and Vaccination Hospital, and I was further gratified to find your excellent article widely quoted in the daily papers. After all, it is the general mass of the public who are likely to be led away by the specious tales and one-sided reasoning of the anti-vaccinationists, whom we want to reach. I confess that I think the extraordinary efficacy of the protection from small-pox afforded to our nurses and other employées is largely due to the fact that the lymph which the surgeon makes use of at this hospital he has himself taken from a subject he has operated upon, and of the efficacy of which he is consequently well assured; and, moreover, it is used as nearly as possible from arm to arm. I regret that at the other large institutions of the kind in the metropolis those conditions which appear to me to be essential for the absolute security of those confided to their charge are absent, and that the medical officers at such hospitals are compelled to make use of lymph of the quality of which they cannot themselves be absolutely certain. I cannot conclude also without expressing my regret that at the present day, notwithstanding the amount of evidence we have on the subject, a medical man of the standing of Surgeon-Major Pringle should, as in his recent lecture before the Society for the Encouragement of Arts, &c., publicly state his disbelief in the necessity for revaccination in adults who have been efficiently vaccinated. Such a statement is, I think, eminently calculated to encourage the present apathy of the general public as regards revaccination, and is certainly not warranted by the statistics of his professional brethren, at all events in Europe.—I remain, Sir, yours faithfully,

HERBERT GOUDE, F.R.C.S. Edin.
Small-pox and Vaccination Hospital, Highgate-hill, N.,
May 9th, 1885.

LIVERPOOL.

(*From our own Correspondent.*)

HOSPITAL SATURDAY IN LIVERPOOL.

SATURDAY, April 25th, was observed here as Hospital Saturday, boxes being distributed among all places where large bodies of working men are employed, and cages being attached to the street lamps at reasonable intervals. The result will be watched with keen interest this year, extraordinary pains having been taken to ensure the increased success of this mode of obtaining the working men's support to the hospitals, which are such a benefit to them. The amount collected in former years, averaging between £400 and £500, has been justly regarded as considerably less than what might be expected in so large a district, containing such an enormous number of working men. Up till the 9th inst. the sum of £2357 had been received; more is expected to come in. To enhance the success of the movement this year, and to assist the general committee, a committee of working men was appointed last year, and at a meeting of the former, on the 7th inst., the following resolution was carried unanimously: "That this committee hereby offer their thanks to the working men's committee for their valuable assistance in increasing the amount of the Hospital Saturday contribution, and express the hope that their services will be continued."

THE SCHOOL OF MEDICINE.

The summer session commenced on the 4th inst. Considerable alterations have been made in the anatomical department of the building, by which further accommodation will be afforded, and an increased number of students will be enabled to dissect conveniently to themselves and to each other. On the 11th inst. there were nine subjects in the dissecting-room, on which between thirty and forty students were practising dissection. Mr. Frank T. Paul, formerly surgical tutor, now lectures on Medical Jurisprudence and Toxicology. At the recent examination ten students from this school passed in Anatomy and nine in Physiology, only one being rejected in both subjects.

THE LIVERPOOL UNIVERSITY COLLEGE.

At the last meeting of the Council of University College, a gift of £1500 was announced as having been received from Mrs. Sheridan Muspratt, widow of the late eminent Professor of Chemistry. This sum is to be applied for the endowment of a scholarship or scholarships in furtherance of the study of chemistry, and in commemoration of her late husband.

THE SPRING ASSIZES.

At the recent assizes the calendar was unusually light, there being no charge of murder and comparatively few cases of violence. What is still more remarkable, there was not a single charge of rape or criminal assault on females, although these assizes comprise the whole of South-west Lancashire with a number of small county towns, where such crimes have been lamentably frequent of late. It is therefore probable that the very severe sentences passed for those offences by Mr. Justice Day, who at the last three assizes presided in the Crown Court, have had their effect.

THE LATE MR. FREDERICK PHILIP PHELPS, SURGEON, OF EXETER.

The tidings of this gentleman's death under the melancholy circumstances noticed in last week's LANCET will be received with sincere regret by many local readers, who will remember the deceased when he was house-surgeon at the Northern Hospital more than twenty years ago. He was extremely popular with all who knew him, from his unvarying kindness to all with whom he had to deal, whether colleagues, subordinates, or patients, as well as his genial humour and constant cheerfulness.

BIRMINGHAM.

(*From our own Correspondent.*)

LAUDANUM IN WHOOPING-COUGH.

IT seems to be a Utopian idea that in the care for sick children among the poorer classes intelligence and prudence in the use of patent drugs will ever be the rule and not the exception. An inquest was held a few days ago on the body of a child ten and a half years old, who had suffered from whooping-cough. The mother, on the advice of a neighbour, purchased a pennyworth of laudanum, mixed it with vinegar and treacle, and gave it to the child a teaspoonful at a time. The quantities of the two latter ingredients are not mentioned, but the result showed that they could not have been large, for the child died after the second dose. The mother stated that she informed the chemist that she intended to give the compound to the child as physic, but no restrictions are placed upon the sale of powerful drugs with such an intention. The verdict of death from misadventure carries but poor comfort with it, and will probably not go far in teaching this class that the use of opium for young children, even in small quantities, is highly dangerous and improper in unskilled hands.

DAMAGES FOR THE BITE OF A DOG.

It is interesting to note a judgment given in the county court for damages in a case of this kind. The plaintiff, a working man, claimed £100, and was awarded £36, for the loss of time and injury caused to his leg. Fortunately for the patient he was able to prove that the dog was a ferocious one, and accustomed to bite mankind, and the law which allows compensation only under these circumstance enabled him to make his claim good. It is well that those who keep vicious dogs with a known propensity to bite people should be aware of the pecuniary risk attending such an indulgence.

TEMPERANCE ADVOCACY.

At a recent conversazione of the Ladies' Central Temperance Association a distinguished physician was selected to hold forth in support of the cause so strongly espoused by the Association, and to denounce the use of intoxicating beverages. To the consternation of the audience, however, though brought to curse, he remained to bless, and in forcible language he dwelt upon the intemperate temperance of some abstainers. In glowing terms he upheld the good which in occasional circumstances moderate drinking is capable of effecting, and pointed out the value of the judicious use of alcohol. His position, which he described as logically and scientifically sound, somewhat startled his audience; and if it did no more, must have aroused them to think how far they were right in not clearly ascertaining his views before they sent a deputation to ask his countenance and support at such a meeting.

Birmingham, May 13th, 1885.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE MEDICAL COLLEGE AND THE CORPORATION.

THE premises at present occupied by the College of Medicine are likely to be taken over for railway extension, and an application has been made to purchase, I understand at a cost of £10,000, an eligible site in one of our principal thoroughfares. The Corporation is the trustee of the site, and it so happens that it is part of an ancient charity left for the benefit of the poor of the city. I believe it is the contention of the medical authorities that the grant of the site would be a great benefit to medical education and an advantage to the city from the number of resident students attending, and so be an indirect advantage to the poor as in some way adding to the trade of the city and paving the way for its becoming some day the seat of the University of Newcastle. This view was advanced with great ability and eloquence by Dr. Heath, who headed a deputation from the College to the Corporation the other day. The granting of the site on the terms proposed by the College is held by some members of the Corporation at least as being beyond the powers of their trust, seeing that the College only offers £10,000 for a site worth, at least, three times as much, and that in this matter the College is to be treated as any other purchaser making an offer for the land. But on the other hand, Dr. Heath pointed out that "the proprietors of the College building could a few years ago have sold the building with profit and divided the proceeds among themselves, but that they scorned to do anything of the kind; they held it for public use and for the benefit of medical education." The question has been now well and forcibly put before the Corporation, and it is to be hoped it may be decided solely on its merits.

NEWCASTLE NATURAL HISTORY MUSEUM.

All visitors to Newcastle should visit the museum of the Natural History Society, which, it will be remembered, was opened by the Prince of Wales on his late visit to our city. The museum is now in very complete condition so far as a museum can ever be considered so, in view of the many additions a good one must from time to time receive. Only just lately Miss Mary Hancock presented the complete set of the original drawings of the British Nudibranchiate Mollusca, the work of her late brother, Mr. Albany Hancock. These drawings were made by him to illustrate a large work published by the Ray Society. By the perfectly natural and clear manner in which details are shown, this work sheds much light on a group of creatures till then comparatively unknown even to naturalists themselves. For another work, illustrated by beautifully and delicately elaborated drawings which Mr. Albany Hancock had undertaken at the urgent request of several scientific friends in London, he received the gold medal of the Royal Society for 1858. This presentation was the first ever made to a native of Newcastle. The Bewick collection and the Hancock drawings are now on the walls of our museum, and well worthy of a visit from all interested in nature and art.

VACANT HOSPITAL APPOINTMENTS IN NEWCASTLE.

There is now an unusual number of hospital appointments vacant in Newcastle. As well as the vacancy at the Chest Hospital, mentioned last week, an honorary physician and surgeon is wanted at the Children's Hospital. Dr. J. G. Houseman and Dr. Coley are candidates for the physician's post and Dr. Aitchison and Mr. W. Glaholm Black for the surgeoncy. At the infirmary Dr. Limont is, so far as I have heard, the only candidate for the vacant physicianship. Dr. Limont has been acting as senior resident medical officer to the house for more than three years. For some time he has devoted himself specially to physician's work; and he asks the committee to release him from the post to enable him to compete for the higher appointment.

Newcastle-on-Tyne, May 11th.

EDINBURGH.

(*From our own Correspondent.*)

A LIME-LIGHT FOR DEMONSTRATION PURPOSES.

AT the fortnightly meeting of the Edinburgh Medico-Chirurgical Society, Dr. Foulis gave a demonstration of the circulation in the web of a frog's foot and of some botanical test objects by means of the oxyhydrogen light. The light, transmitted through a powerful condenser, passed through an ordinary microscope lens, and was thrown upon a large plate of ground glass at a distance of about 25 ft. The image of the object demonstrated could be focused on this plate with great exactitude, the definition even with high powers being excellent, and the general effect strikingly satisfactory.

A RARE FORM OF ICHTHYOSIS.

Dr. Allan Jamieson exhibited a drawing from a case of ichthyosis palmaris et plantaris. The palms and soles of the patient were covered with a horny growth a quarter of an inch thick, which gave a loud resonant note when struck. All other parts of the skin were absolutely normal, and the only other morbid symptom was the very rapid growth of the nails both of the fingers and toes. In Dr. Jamieson's experience a case of ichthyosis with such exact delimitation of the areas affected was absolutely unique.

SUBPERIOSTEAL SURGERY.

Dr. C. W. MacGillivray exhibited portions of bone removed subperiosteally from the lower end of the humerus in a case of compound fracture and dislocation. The whole of the bone removed was replaced by a new formation, and the result of the operation was a movable and useful joint.

LARYNGEAL PARALYSES.

Dr. McBride read a paper on the above subject, dealing specially with bilateral paralyses, and illustrated by the records of several interesting cases. An observation of some importance was the detection of paralysis of both laterales in a case of locomotor ataxia, in which all the usual symptoms were well marked. He specially insisted on the value of laryngeal examination as an important adjunct to the diagnosis of various morbid conditions.

THE SCIENCE AND ART MUSEUM.

An extensive addition has just been commenced which will complete the Museum buildings as originally designed. For some time there has been overcrowding of specimens in several of the departments, rendering increased accommodation very desirable; and the crying need for a properly fitted library, where the public can avail themselves of the valuable collection of books possessed by the Museum, will at length be satisfied. Colonel Murdoch Smith has been appointed Director, a post left vacant by the sudden death of the late Professor Archer. Colonel Smith has a considerable reputation as an antiquarian, and has enriched both the British and South Kensington Museums by valuable collections made in the East. These public services have received their due recognition in the important post to which he has been appointed; and there is every reason to expect that he will prove no unworthy occupant of the place once filled by such men even as the genial and versatile Dr. George Wilson.

Edinburgh, May 11th.

IRELAND.

(*From our own Correspondent.*)

ROYAL COLLEGE OF SURGEONS.

AT the last meeting of the Council, a letter was received from Mr. O'Reilly-Dease offering a portrait of Mr. Butcher, the eminent Dublin surgeon, and also proposing to build a hall for the reception of Mr. Butcher's museum, in the event of that gentleman giving it to the College. Dr. Cameron vice-president of the College, stated that he was authorised by Mr. Butcher to offer his museum, and that Mr. Wheeler, to whom Mr. Butcher had promised to bequeath it, had kindly waived his claim. On the motion of Mr. Colles, seconded by Sir George Porter, the thanks of the Council were voted to each of the gentlemen concerned. The annual election of examiners, which had been arranged to take place on the 19th inst., has, in view of the expected new charter, been postponed to the 27th. It is confidently expected that several changes will occur, and some new blood be infused into that body. Among the various candidates who will come forward will be Mr. Swanzy to examine in ophthalmic surgery, Dr. Mapother in physiology, and Dr. Robinson in anatomy.

DEATH OF MR. JOHN NEILL, RESIDENT SURGEON, STEEVENS' HOSPITAL.

It is with deep regret I record the death of this promising young surgeon, at the early age of twenty-five, from blood poisoning. He died rather suddenly, and it is a doubtful point whether the cut which he received on making a post-mortem examination and which caused the blood poisoning was complicated with scarlatina or not. Mr. Neill was a private teacher of considerable repute, and was connected with the Ledwich School of Medicine as a demonstrator of anatomy, where he was much liked and where his loss will be greatly felt. Thoroughly straightforward in all his actions, kind in disposition, and unassuming in manner, he made friends everywhere, and his sudden and untimely decease is widely regretted. Mr. Neill's funeral took place on Tuesday last and was largely attended, a notable feature being the presence of about one hundred students, who walked in procession from Steevens' Hospital to the place of interment. It is contemplated by the students to present an address of condolence to Mr. Neill's father on his sad bereavement.

Dr. H. B. Fleming has been unanimously elected medical officer to the Omagh workhouse, in the room of his father, Dr. H. Fleming, resigned.

At a meeting of the Royal Cork Yacht Club, last week, Dr. Tanner was removed from the list of members on account of his action on the occasion of the Royal visit.

Small-pox is reported to have broken out at Enniskillen.

Dublin, May 12th.

ROYAL COLLEGE OF SURGEONS.

AT an ordinary meeting of the Council of the College, held on Thursday, May 14th, the usual resolutions were passed fixing the date (July 4th) for the election of members of Council, in place of Messrs. Erichsen, Holmes, and Savory, who retire. It is probable that the two former will not seek re-election.

The report of the Committee in reference to the required certificate of instruction and proficiency in the practice of vaccination was received as follows:—"The Committee recommend to the Council that the existing regulation on the subject of the recognition of certificates in vaccination should remain in force, not only on account of the obligations of the College to the Local Government Board in England and the agreement with the Royal College of Physicians under the Scheme for the Examining Board in England, but because by recognising other certificates the value of the diploma would be depreciated to future Members of this College. The Committee have, at the same time, further to report that they have reason to believe that if a representation were made by the Council of Queen's College, Belfast, to the Irish Local Government Board suggesting that that Board should invite the English Local Government Board to confer with a view to the establishment of educating vaccination stations in Ireland, subject to terms to be agreed upon by both Boards, the difficulty under which Irish candidates for the diploma of this College now labour might be surmounted."

The following recommendations of the Committee of Management were approved:—"1. That every member of the University of Edinburgh who shall have passed such an examination or examinations at his university as shall comprise the subjects of the First and Second Examinations of the Examining Board in England, and who shall have completed not less than four years of medical study according to the regulations required by his university, be eligible for admission to the Third or Final Examination of the Board, two years after his having passed all the other required examinations; that every candidate so admitted to examination be required to pay a fee of five guineas; and that every such candidate who shall have passed such Third or Final Examination shall, on the further payment of not less than twenty-five guineas, and subject to the bye-laws of each College, be entitled to receive the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England. 2. That the regulation exempting candidates, members of universities, from any part of the examinations of the Examining Board in England do continue in force so long only as the examinations of the universities shall be satisfactory to the Committee of Management. 3. That the regulation applicable to the conditions of the admission of members of the English universities to the Third or Final Examination of the Examining Board in England be extended to such of the Scotch and Irish universities as require that not less than two of the four years' curriculum of professional education shall have been spent in residence at the university."

The President and Vice-Presidents' report on Sir James Paget's resolution, that a marble bust by Mr. Brock, A.R.A., of Sir Erasmus Wilson be placed in the College, was adopted.

The following motion, of which he gave notice at the last meeting, was moved by Mr. DURHAM, seconded by Mr. SAVORY, and carried unanimously:—"That seven delegates from this College be appointed with authority to invite an equal number of delegates from the Royal College of Physicians to meet and confer upon what steps, if any, can be taken to enable the two Colleges to obtain the legal right of giving the title of 'Doctor' to persons who shall have obtained the licence of the Royal College of Physicians of London and the diploma of the Royal College of Surgeons of England."

The delegates appointed were: the President, the Vice-Presidents, Sir Joseph Lister, and Messrs. Marshall, Hulke, and Durham.

MEDICAL NOTES IN PARLIAMENT.

The Case of Mr. Hillman.

IN the House of Commons on the 7th inst., in reply to Mr. W. Corbet, who asked whether it was true that in the Court of Appeal the Lord Chief Justice of England decided in favour of Mr. Hillman, while two other judges held opposite views; and whether he would cause the law regarding the confinement of persons alleged to be insane to be so altered as to be intelligible to those who had to administer it,—Sir W. Harcourt stated that the Court of Appeal seemed to have decided that the detention of Mr. Hillman was lawful, and he could not admit that he was unlawfully placed in the asylum. He had no doubt the attention of the Lord Chancellor would be called to this matter in connexion with the Bill now under consideration.

Inoculation for Cholera.

On the 8th inst., in reply to Dr. Cameron respecting the discovery reported to have been made by Dr. Jaime Ferran of Valencia, in connexion with inoculation for cholera, Lord E. Fitzmaurice stated that Her Majesty's Minister at Madrid would be instructed to send home translations of any papers of Dr. Ferran's, and reports of the Madrid Academy of Medicine on the subject.

The Royal University (Ireland).

On the 11th inst., in reply to Mr. Kenny, Mr. Campbell-Bannerman stated that a power was granted to the Senate of the Royal University in their original charter, but lasting for three years only, with a view to facilitating the obtaining of degrees by medical men qualified before the passing of the Royal University Act. It expired in November last, and the Senate have not sought to have it renewed. There was an obvious reason for giving it in the first instance, which does not now hold good, and he was not aware of any intention to revive it.

Mortality from Small-pox.

On the 12th inst., in reply to Mr. Hopwood, Mr. G. Russell stated that two tables as to the mortality from small-pox, which were compiled respectively by Dr. Greenhow and Dr. Farr, could be found in the Appendix to the Report of the Select Committee in 1871 on the Vaccination Acts. According to these tables, the small-pox death-rate in London was 3044 per 1,000,000 in 1746-55; and 5020 per 1,000,000 in 1771-80. In 1871-80 the mortality, according to the returns of the Registrar-General, was 460 per 1,000,000.

Medical Relief and the Franchise.

On the report of the English Registration Bill, Mr. Davey moved the addition of a clause providing that the receipt of parochial medical relief should not disqualify a voter. The clause was opposed by the Attorney-General; but after some considerable discussion was carried by 87 to 50.

The Hospital on Quarantine Island.

On the 14th inst., Lord Hartington, in answer to Lord E. Cecil, who inquired whether he would ascertain if it was true that the Auxiliary Hospital on Quarantine Island, at Sawakin, stood on an old burial-ground, and that great sickness prevailed there just now in consequence of the unhealthiness of the situation, said that there was a hospital which had been selected by the authorities on the spot. When it was first suggested, he had doubts as to the salubrity of an island that had been a burial-ground. A telegram was sent to Sawakin, and in reply he was informed that the island was most healthy. For six years past scarcely a burial had taken place, and there was no reason to believe it would be unhealthy.

Vaccination.

Mr. G. Russell, replying to Mr. Hopwood, who asked whether the President of the Local Government Board was aware that by a house-to-house visitation of 15,000 houses in West Ham, instituted by Dr. Kennedy, it had been ascertained that the inhabitants are vaccinated in number up to the average of 98 per cent., said the figures in the question were inaccurate. Some complaint had been made of the system of sewers and drains in West Ham, and he had directed an inspector to make inquiries on the spot.

Overwork at School.

Mr. Mundella, in answer to General Feilden as to whether it was true that a young girl had committed suicide on account of overwork at school at Adlington, said inquiry had been made, and it was found that she was the daughter of a dairyman and worked in a cotton mill. As she was under thirteen, she attended school half-time, was in a low standard, and had no home lessons. She had a deal of farm work to do in carrying out milk. Her companions said she had complained of harsh treatment on the part of the woman who employed her at the factory, and that was the cause of her suicide. The school was well conducted, and no blame attached to the teacher in this case. Mr. Mundella added that more labour was exacted from children of tender years in England than in any other country in Europe.

The Sanitary Conference at Rome.

Lord E. Fitzmaurice, in reply to Mr. Sutherland, said Her Majesty's Government have accepted an invitation to a scientific and sanitary conference which is about to meet at Rome, and will examine the best methods of preventing the spread of cholera. Sir Guyer Hunter, who was employed in Egypt during the epidemic of 1883, and whose valuable reports have been laid before Parliament, and Dr. Thorne, the Assistant Medical Officer of the Local Government Board, will be the British delegates. The recommendations of the Conference will be in the usual course submitted to the

Governments represented, but will not have any binding force until they have been adopted by those Governments. It would be contrary to practice to make public at present the instructions given to the British delegates.

Obituary.

DR. DIOMEDE PANTALEONI.

THIS distinguished physician and patriot, whose death on the 3rd inst. we announced last week, was born seventy-seven years ago at Macerata, an ancient university town in the Marches. There he prosecuted his studies, preparatory and professional, and there he took his degree. Like many public-spirited Italians of that day, he was swept into the vortex of the revolution, and his time was pretty evenly divided between medical practice and politics. From 1848 to 1860 the States of the Church were in periodical upheaval, and shortly after the former of these dates Dr. Pantaleoni, who had settled in Rome, and had rapidly risen in public esteem as an able and accomplished physician, had from pontifical persecution to expatriate himself. This part of his career is dramatically described in his countryman Ruffini's "Doctor Antonio," of which fascinating tale he is known to be the hero. "He enjoyed," says the leading Italian journal, the *Opinione*, "the confidence of Count Cavour, and of that great minister's chief coadjutors in the work of national unity, while the historian will one day record the many onerous political missions carried out with sagacity and courage by the practitioner from the Marches—missions fraught with the best results for the complete liberation of Italy, and for her harmonious unification under the house of Savoy." In 1851 he was in London, the intimate friend of many leaders of the profession, and assisting in a silent and successful way the movement for that consummation which all true Italian patriots had at heart. Massimo D'Azeglio, the then Prime Minister of the Sardinian Government, had thus recommended him to his nephew, Emanuele D'Azeglio, the representative of King Victor Emanuel at the British Court:—"Pantaleoni is my familiar. He is the leading consultant physician to the foreigners in Rome; he is my right-hand man in all my chief transactions; no believer in the Republic, the promoters of which wanted to stiletto him; a Monarchist of lofty character and equal intelligence; an excellent person in all respects, and devoted to our views. Get him to speak on Italy, and you will find his talk worth volumes." Scarcely had the country organised itself constitutionally, when his native Macerata chose him as her representative in the national Parliament, and Cavour employed him in an important series of overtures to bring about, through Cardinal Santucci, a *modus vivendi* with the Papal Court. In 1873 he resigned his seat in the Chamber of Deputies, and by the royal decree of Nov. 6th of that year he was made a Senator of the Kingdom, in which capacity he did splendid service, particularly on all questions of academic education and of sanitary reform. All this time he was in extensive practice, not only among his fellow countrymen, but also among the foreign visitors who annually resort to Rome, many of whom are alive to attest his painstaking and successful treatment. To the Accademia Medica di Roma and the Royal Institution of the "Lincei" he contributed numerous important papers, the more practical of which are, we believe, about to be collected and to assume an independent and enduring form. On all questions of the climate of Rome, her water-supply, and the rules to be observed by the stranger within her gates, he was an acknowledged master; while no properly accredited professional brother, whatever his nationality, ever sought his advice in vain.

Among the works with which he employed the spare hours of his busy days and nights may be mentioned the "Storia Civile e Costituzionale di Roma dai suoi Primordi sino agli Antonini" (Civil and Constitutional History of Rome from its first beginnings to the Antonines), and "L'Ultimo Tentativo del Cavour per la Liberazione di Roma nel 1861" (The last attempt of Cavour for the Liberation of Rome in 1861). From these, especially the former, may be gathered some notion of his wide and deep knowledge and his vigorous thinking, while their style has all the characteristics of the independent investigator schooled in scientific and classical study.

His funeral, which took place on Tuesday, the 5th inst., was a public one. His native town of Macerata having signified its wish to possess his remains, these were accompanied from his house in the Via Ripetta to the railway station, the *cortège* being thus composed:—A company of the Municipal Guards, followed by a military band performing a dead march, and by a battalion of the 79th Infantry. Next came the hearse, covered with magnificent wreaths, contributed by the Town Council and by the chief learned societies; and this, again, was followed by a numerous train of senators, members of the legislative body, the leading physicians and surgeons of the city and province of Rome, representatives of all the scientific associations, and many personal friends in carriages or on foot. The cordons of the hearse, which was surrounded by the ushers of the Senate House, were held by General Durando, the President, and the Marquis Caracciolo Di Bella, the Vice-President, of the Upper Chamber; by Signor Tartufari, Councillor of the Court of Cassation and representative in Parliament of the constituency of Macerata; the Senator Count Cadorna, President of the Council of State; Dr. Bastianelli, Municipal Assessor; Professor Guido Baccelli, President of the Academy of Medicine; the distinguished Hellenist, Mariotti; and Signor Gravina, Prefect of Rome. The route along the Corso and Via Nazionale was lined by a dense and respectful crowd, and on the *cortège* reaching the station, the Commendatore Righetti, the most intimate friend of the deceased, pronounced a funeral oration of singular propriety and power. The coffin, having been consigned to the Ancona train, was received by the Municipality of Macerata, the scene of interment.

Medical News.

COLLEGE OF PHYSICIANS IN IRELAND.—At the May examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Elizabeth Bielby, Theodore D. Browne, Fitzwilliam Richard Augustus Evans, George Edw. Joseph Greene, Wilson Mills Nugent, Henry Stoker, M. Andrew Wade, Joseph Theophilus Weston.

MIDWIFERY.—Elizabeth Bielby, Theodore D. Browne, Thomas Joseph Dillon, Fitzwilliam Evans, George Edward Greene, Samuel Horneck, Henry Stoker, George Scott Tate, M. Andrew Wade, J. Theophilus Weston.

The undermentioned have been admitted Members:—

James Ellis. | Samuel Hamilton.

UNIVERSITY OF DUBLIN.—The following degrees have been recently conferred by the Senate of this University:—

BACHELOR IN SURGERY.—Orlando Palmer Beater, Andrew Grierson Faussett.

BACHELOR IN MEDICINE.—Orlando Palmer Beater, Andrew Grierson, Faussett.

DOCTOR IN MEDICINE.—Orlando Palmer Beater.

ROYAL UNIVERSITY OF IRELAND. — The undermentioned have passed the M.B. Examination of this University:—

Samuel Alexander, John Barron, James R. Burrows, Alexander Corry, *G. B. Crawford, M. H. Curtin, T. W. Dwyer, Robert English, G. H. Foott, R. E. Foott, R. M. Griffin, M. H. Hannigan, W. R. Hawkins, Daniel Hennessy, W. J. Loughrey, J. McAleer, Michael McCarthy, W. B. McWha, G. F. Marks, John Meenan, *J. Musgrave, James J. Nagle, John J. O'Brien, J. P. O'Byrne, R. Pettierew, *E. L. Pooler, *John Ryan, J. Martin Savage, William Sexton, J. Henry Sharpe, Norman Smythe, *R. Thomson, *F. J. Tresillan, J. J. Walsh, M. J. Whitty, Samuel Wilson.

*Permitted to compete at the Honours Examination.

THE new workhouse infirmary at Croydon, erected at a great cost, is to be opened to-day (Saturday) by the Archbishop of Canterbury.

GLAMORGAN AND MONMOUTH INFIRMARY. — Miss Shand, who died recently in the Principality, has bequeathed £8000 to the trustees of the infirmary.

DANIEL MURRAY O'HARA, surgeon, sentenced to ten years' penal servitude for extortion, is reported to have strangled himself in Liverpool Gaol on the 7th inst.

AT the annual dinner of the Royal Hospital for Children and Women, which was held on the 13th inst., subscriptions amounting to more than £80 were received.

VACCINATION GRANTS.—Dr. Dugald Campbell, of Alfreton, Derbyshire (second time), Mr. Peter Swales, of Sheerness (seventh time), and Mr. T. Osborne-Walker, of Crick, Northamptonshire (second time), have received the Government grant for efficient vaccination.

Presentation.—Miss Williams, who was for seven years matron at St. Mary's Hospital, has been presented by her friends at the institution with an illuminated address and a silver tea-service.

London Fever Hospital.—The Lord Mayor has consented to preside at the second festival dinner in aid of the London Fever Hospital, which is to be held at Willis's Rooms on Tuesday, June 23rd.

University College, London: Faculty of Medicine.—The distribution of prizes will take place on Wednesday, May 20th, at 4.30. The Right Hon. Lord Justice Fry, M.A., F.R.S., Vice-President of the College, will preside.

Animal Vaccine.—It is stated that the authorities of Strasburg have published a regulation making the use of animal lymph for vaccination compulsory. Offices for its supply are to be inspected every ten days by the Government vaccinators.

The annual general meeting of the Royal Medical Benevolent College will be held on the 21st inst., when the result of the polling for pensioners and foundation scholars will be announced. All balloting-papers are to be returned not later than the evening of the 18th inst.

At a meeting of the Anthropological Institute on the 12th inst., the Earl of Northesk exhibited a collection of specimens of worked Jade from New Zealand. Mr. J. H. Kerry-Nicholls read a paper on the Origin, Physical Characteristics, and Manners and Customs of the Maori race.

The Meath Hospital, Dublin.—The following gentlemen have been awarded prizes for the Winter Session 1884-5:—Senior Medical Prize: Henry Walter; Junior Medical Prize: John T. Russell. Senior Surgical Prize: R. D. Penefather, John T. Russell, and William J. Taylor, equal; Junior Surgical Prize: Alfred William Bewley, 1st, A. E. Mahood, 2nd.

A meeting of graduates of the University of Aberdeen was held in Manchester on the 6th inst., for the purpose of welcoming Professor Ogston on his return from the Soudan. In his speech Dr. Ogston dwelt at some length on his Sawakin experiences, stating his high approval of the efficiency of the Army Medical Department and the care with which the wounded were treated.

The Report of Colonel Haywood, engineer and surveyor to the Commissioners of Sewers, on the works executed by the Commission during 1884, has been issued. It states that the total length of sewers constructed during the year was 1163 feet, of which 1070 feet were upon the lines of old sewers. The Metropolitan Railway Company in connexion with their works between Cannon-street and Aldgate had to construct new sewers to the extent of about 7190 feet.

The Zoological Society of London.—At the fifty-sixth anniversary meeting of this Society, which was recently held, Mr. William T. Blanford, F.R.S., Dr. A. C. L. G. Günther, F.R.S., Dr. Edward Hamilton, Mr. E. W. H. Holdsworth, and Surgeon-General L. C. Stewart were elected to the Council in place of the retiring members, and Professor W. H. Flower was re-elected president, Mr. Charles Drummond, treasurer, and Mr. Philip L. Sclater, M.A., Ph.D., F.R.S., secretary to the Society for the ensuing year.

University of Cambridge.—There will be an examination in certain branches of natural science for minor scholarships at Downing College on Tuesday, June 2nd next, and following days. Persons who have not entered at any college in the University are eligible to these scholarships, which will be of the value of from £40 to £70 per annum, and tenable until their holders are of standing to compete for a foundation scholarship. Further information will be given by Dr. Perkins or the Rev. J. C. Saunders, tutors of the College.

Royal National Lifeboat Institution.—The Committee of this Society, which has now been established sixty-one years, in their annual report for 1884 state that during the year twenty-eight new lifeboats were despatched from the store-yard, a number greatly in excess of that sent out during any one year since 1866. The total number of boats now under the management of the committee is 284, which were instrumental in saving no fewer than 633 lives and 18 vessels between Jan. 1st and Dec. 31st, 1884. In the last sixty-one years as many as 31,355 lives have been saved through the instrumentality of the institution. Six silver medals and clasps, nine vote of thanks on vellum, and £5000 in money were granted by the committee for saving life in 1884. The total expenditure of the lifeboat service amounted to £52,724, while the receipts of the institution in subscriptions, donations, and dividends amounted to £44,810.

The late Peter Squire.—Friends of the late Peter Squire will be interested to know that the unveiling of a medallion portrait of him will take place at the Pharmaceutical Society's House, 17, Bloomsbury-square, on Wednesday, May 20th, at 4 p.m., by Sir Spencer Wells, Bart.

Compulsory Notification at Dover.—A meeting, presided over by Sir Richard Dickeson, has been held at Dover, when deputations attended to represent the whole of the sanitary and Local Government Board districts in East Kent. The principal matter which occupied attention was the question of the public notification of infectious diseases. It was decided to forward a memorial to the Local Government Board, urging upon them the desirability of a legislative enactment for the compulsory notification of infectious diseases.

Royal Hospital for Incurables.—The annual dinner in aid of the funds of this institution was held on the 7th inst., when it was stated that there are now 193 inmates and 476 out-pensioners, the qualification for admittance being not simply age or even poverty, but the pressure of incurable disease often combined with both. The expenditure amounts to over £21,000 per annum, and since 1881 it has been found necessary to sell out £15,000 of the funded stock. During the evening subscriptions and donations amounting to £4665 were announced.

University College Hospital.—The festival dinner in aid of the funds of this institution was held on the 13th inst., the Prince of Wales presiding. During last year in-patients had been received to the number of 3152, as against 2849 in the previous year; while the out-patients were 33,743, as compared with 24,187 in 1883. The annual subscriptions to the hospital amount only to £2047, while the necessary annual expenditure is £19,500, and the only reliable income it receives from all sources is £6500. During the evening subscriptions amounting to over £5000 were announced by the secretary.

Midland Medical Society.—Mr. James Harmar, to whose long and most faithful services as honorary treasurer the success of the Midland Medical Society has been largely due, has recently resigned office. The members of the Society, under the presidency of Mr. T. H. Bartleet, have signalised their high appreciation of Mr. Harmar's services by presenting him with an illuminated address, a timepiece, and two silver candlesticks. The contributions overflowed, leaving a surplus, which, at Mr. Harmar's request, has been handed over by his successor, Mr. John Garner, as a donation to the Birmingham Benevolent Society.

Glasgow Royal Infirmary School of Medicine, Winter Session, 1884-85.—Prize and Honorary Certificate List:—Chemistry: Chemical Division—Prize, J. H. Miller. Medical Division—1st Prize, Robert C. Wakefield; 2nd Prize, W. J. France. Honorary Certificates: J. W. Lax, Thos. McCubbin, William McLeod, A. J. Harwood, J. J. Wilson, J. L. Wilson, Alex. McDonald, R. W. Roberts. Anatomy: Senior Division—Prize, Joseph Beadle. Honorary Certificates (in order of merit): J. Owen Jones, Gwllym Evans, J. R. Lloyd Jones, Frank A. Elkins, Edward Brooks. Junior Division—Prize, Robert C. Wakefield. Honorary Certificates (in order of merit): W. R. Walker, W. J. France, J. W. Lax. Practical Anatomy (in alphabetical order): Senior Division—Joseph Beadle, Edward Brooks, Gwllym Evans, Alfred J. Harwood, Hugh Owen Hughes, John Owen Jones, J. R. Lloyd Jones, Thomas C. Jones. Junior Division—W. J. France, John W. Lax, Alex. McDonald, Robert W. Roberts, Robert P. Williams. Physiology: 1st Prize, Robert C. Wakefield; 2nd Prize, John R. Lloyd Jones. Honorary Certificates: John Owen Jones, Frank A. Elkins, Randolph O. Willis. Surgery: Gold Medals, Foden Wilson, Robert H. Parry. Honorary Certificates: Fred. W. Ord, Alfred W. White, William Valentine. Medicine: Prize, Foden Wilson. Honorary Certificate, John Thomas. Materia Medica: 1st Prize, Robert H. Parry; 2nd Prize, Joseph S. Sergeant. Honorary Certificates: Thomas Jones, Edward Brooks, John Owen Jones.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BAILEY, T. RIDLEY, M.B.Ed., has been appointed Medical Officer of Health for Bilston, vice S. G. Gilbert, deceased.

BARNARD, ARTHUR TOMSON, M.R.C.S., L.R.C.P., has been appointed Junior House-Surgeon to the Royal Albert Edward Infirmary, Wigan, Lancashire.

BARNARD, CHAS. E., M.D., has been appointed Health Officer for the Port of Hobart, Tasmania, Superintendent of Vaccinations, and Government Medical Officer, at a salary of £300 a year.

BARROW, FREDERICK, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse, Rothbury Union, vice Todd.

BRIGGS, HENRY, M.B., F.R.C.S.Eng., has been appointed Surgical Tutor at the Liverpool Royal Infirmary, vice F. T. Paul, F.R.C.S.Eng., resigned.

CAHILL, THOMAS, M.D., C.M.R.U.I., has been appointed Honorary Medical Officer to the Wellington Hospital, New Zealand.

HARRIS, DAVID, M.R.C.S., has been appointed Medical Officer *for the* First District of the Holborn Union.

HORAN, EDWARD, M.D., C.M.R.U.I., has been appointed Surgeon to the Charters Towers District Hospital, Queensland.

KENWORTH, JOHN WHITE, M.D.Lond., M.R.C.S., has been appointed Surgeon Superintendent to the Napier Hospital, New Zealand.

MILLER, JOSEPH EWING, A.B., M.B., B.Ch., Trinity College, Dublin, has been appointed House-Surgeon to the Chester General Infirmary, vice Dr. A. Macpherson, resigned.

MORGAN, E. RICE, M.R.C.S., L.S.A.Lond., has been appointed Certifying Factory Surgeon *for the Morriston District*, vice Henry Davies, L.R.C.P.Lond., &c., deceased.

MORGAN, Mr. W., has been appointed Analyst for the Borough of Monmouth.

NASON, C. S. STEPHEN RICHARD, M.D., M.Ch.Dub., has been appointed Medical Officer for the Redmarley District of the Newent Union, vice Boughton.

RANDS, S. JOHN OUTLAW, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Bransford District of the Bosmere and Claydon Union, vice Elliston, resigned.

SALTER, FRANCIS JOSEPH, L.R.C.P., L.R.C.S.Ed., has been appointed House-Surgeon to the Devonshire Hospital, Buxton, vice A. M. Jackson, M.B., resigned.

SHEWEN, ALFRED, M.D.Lond., has been appointed Physician to the Prince Alfred Hospital, and Joint Lecturer on Clinical Medicine, at the University of Sydney.

SIMMONS, HAROLD, M.R.C.S., L.S.A.Lond., has been appointed Physician's Assistant to the Middlesex Hospital.

SYKES, JOHN FRED. JOSEPH, M.B., C.M., B.Sc.Ed., has been appointed Medical Officer of Health for the Parish of St. Pancras, vice Mr. Shirley Murphy, resigned.

SYMES, WM. HENRY, M.D., C.M.Ed., has been appointed Honorary Medical Officer to the Christchurch Hospital, New Zealand.

WILLIAMS, GEORGE HERBERT, M.R.C.S., L.R.C.P.Ed., late House-Surgeon to the Royal Infirmary, Manchester, has been appointed House-Surgeon to the North Lonsdale Hospital, Barrow-in-Furness, vice J. S. Morton, M.R.C.S., resigned.

Births, Marriages, and Deaths.

BIRTHS.

COOPER.—On the 11th inst., at 9, Henrietta-street, Cavendish-square, the Lady Agnes Cooper, of a daughter.

HARDY.—On the 12th inst., at Southville-park Villas, Dulwich, the wife of H. Nelson Hardy, F.R.C.S.Ed., of a daughter.

HARINGTON.—On the 8th inst., at Sherborne Lodge, Cheltenham, the wife of H. N. V. Harington, L.R.C.P.Ed., I.M.D., of a son.

HUMPHREYS.—On the 9th inst., at St. Leonards-on-Sea, the wife of J. H. Humphreys, M.D.Lond., prematurely, of a son (stillborn).

RAKE.—On the 11th ult., at Mucurapo, the wife of Beaven Neave Rake, M.D.Lond., Government Medical Officer, Trinidad, of a son.

MARRIAGES.

EMMETT—DELLER.—On the 7th inst., at the Parish Church, Paignton, Richard Emmett, M.R.C.S., L.R.C.P.Lond., to Georgie V. Deller, of Woodville, Paignton, South Devon.

JACKSON—PRIESTLEY.—On the 6th inst., at St. Mary Abbot's, Kensington, by the Rev. H. Webb-Peploe, M.A., Herbert Francis Vaughan Jackson, M.R.C.S., L.R.C.P.Lond., son of the late Sidney Vaughan Jackson, Esq., of Ballina, Co. Mayo, to Amy, only daughter of the late Robert Priestley, Esq.

WATSON—O'DONNELL.—On the 23rd March, at [illegible], N.W.P., India, Surgeon J. Watson, M.D., Medical Staff, Lucknow, to Florence, fourth daughter of J. W. O'Donnell, Esq., C.E.

DEATHS.

EDWARDS.—On the 11th inst., Mary Edwards, wife of Henry Edwards, Surgeon, Lichfield, only daughter of the late Godfrey Hi[illegible], of Lang[illegible] Hall, S[illegible], aged [illegible].

FIELD.—On the 12th inst., at 31, Lower Seymour-street, Portman-square, Hor[illegible], the infant daughter of George and Pauline Field, aged 16 months.

PANTALEONI.—On the [illegible] inst., at Rome, Il Commendatore D. Pantaleoni, M.D., Senator of the Kingdom of Italy.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

The late General Gordon on Medical Missions.

In the quarterly paper of the Edinburgh Medical Missionary Society, issued in May, is published a letter from the late General Gordon to the Rev. A. W. Schapira, Church Missionary Society missionary at Gaza, Palestine, in which he says that the fact of the inhabitants of cities like Gaza being fanatical is in a great measure due to their only knowing Europeans by repute, and expresses the opinion that by such establishments as hospitals a great moral effect is produced.

M.D.—We greatly prefer that clubs should pay 5*s.* or 6*s.* per member; but the sum named is not to be rejected.

CARDIAC MURMURS IN THORACIC ANEURYSMS.

To the Editor of The Lancet.

Sir,—Will any of your readers enlighten me as to the following. A female patient was admitted into this infirmary some time ago for cardiac disease. On admission, she complained of pain over the apex of the heart, with great palpitation. On stethoscopic examination, a loud diastolic murmur was heard over the apex region (that being the point of maximum intensity), by myself and several medical men. A few days back she had severe hæmoptysis, and gradually sank. On making a post-mortem examination, the following was revealed: A true aneurysm of the commencement of the arch of the aorta; there was very slight atheroma of the internal surface of the tumour; the cardiac valves were intact, and the heart and lungs normal. Now arises the query, Why this pain, hæmoptysis, and murmur? Was it conveyed along the wall of the ventricle and so intensified at the apex? Or was it due to the patency of the semilunar valves, produced through the agency of the aneurysm? We have it from authorities on the subject that murmurs are the exception, and not the rule, in thoracic aneurysms.

Having seen an almost similar example some time ago, and failing to find any mention of such statements as the above in any books on the subject, is my excuse for occupying your space.—Yours faithfully,

W. Gem.

City Infirmary, E., May 11th, 1885.

Medicus.—The question has been asked and answered more than once in our columns. (See The Lancet, June 16th, 1883, p. 1076.)

FEES FOR LUNACY CERTIFICATES.

To the Editor of The Lancet.

Sir,—A few months ago I was called upon to certify a lady of unsound mind whom I had attended for a mental affection some weeks before, and on sending my account for the certificate (£1 1*s.*) the other day was informed that on two previous occasions on which she had been certified her then medical attendants made no charge for the certificates, as they had been in previous attendance. Having never before heard such a fee disputed on this ground, I should be glad if some of your readers would kindly tell me the custom or rule in such cases.

I am, Sir, your obedient servant,

Lux.

May 8th, 1885.

THE ACTION OF IRON ON THE SYSTEM.

G. BUNGE, in the *Zeit. Physiol. Chem.*, describes experiments on the form in which iron exists in egg yolk. He is led to believe that food does not contain iron in inorganic combinations, but that it only exists in complex organic compounds which have been formed by the vital processes. It is absorbed and assimilated in this form, and then converted into hæmoglobin. This is, he is aware, apparently at variance with the observations of practical physicians. The apparent contradiction may, he thinks, be explained by the hypothesis that inorganic iron salts prevent the decomposition of the organic iron compounds in the intestinal canal.

Lex.—The legitimacy might be questioned, but its possibility could not be denied.

WE are unable to find room for *Dr. Gilbert's* letter in our present number.

MEDICAL MISSIONS AS FIRST AIDS TO CHRISTIANITY AMONGST THE HEATHEN.

To the Editor of THE LANCET.

SIR,—The annotation upon "Medical Missions" in your issue of Feb. 14th last stimulates me to give you an independent account of my personal observations of this kind of work in operation amongst the heathen natives of South Africa.

So far as I have been able to discover during my travels in this part of the world, and so far as medical mission work goes, there appear to be three classes of mission stations in South Africa:—1. Those which do not dabble with medicine. 2. Those which do dabble with medicine to an amusing degree. 3. Those which either have a resident medical officer or are within reach of medical aid. The missionaries I have spoken to in charge of stations coming under Class 1 give me as their reason for not prescribing for sick natives that they know nothing about medicine or drugs beyond castor-oil or Epsom salts. Those in charge of stations coming under Class 2 have informed me that they feel perfect confidence in their ability to undertake any medical or surgical case. At these stations I have seen well-stocked surgeries and surgical instruments, from vaginal speculums to midwifery forceps and tooth instruments. Those stations to which a medical officer is attached are very few and far between—in these parts at least; I am only personally acquainted with one; but his (the doctor's) presence is not felt by the surrounding natives, his duties being limited to teaching in the Young Men's College, and in professionally attending the staff of the particular mission connected with his sect or denomination. By paying, natives and Europeans can, however, see the doctor. Not many miles from this station there is another large mission station, with a free dispensary attached; but a lady has charge of the drug department and prescribes for the sick and the lame. But in not a single instance did I meet with, or hear of, a medical mission station, working as such, in connexion with or independently of any of the numerous mission stations scattered about in the interior or lower parts of Africa. In all directions all I could hear was that there were no funds for developing "medical mission" work. For nearly four years I had medical charge of a Government (colonial) dispensary and hospital, at which more than [illegible] sick were relieved annually (*vide* Blue Books, 1882-83-84). There was another medical establishment similar to the one under my own charge in the same territory; both were working an enormous amount of good, and both were closed upon the plea that there were no more funds left to carry on either the one or the other. During the existence of these dispensaries and hospitals, it was a rare thing to hear of witchcraft, "smelling-out," or other barbarous proceedings connected with disease or the sick and suffering; but, strange to state, within a few months of their being closed the native doctors could be met with everywhere, witchcraft again came into practice, and "eating-up" and "smelling-out" (practices connected with witchcraft) rapidly developed, with all their cruelties. However, the field is still open and "cut and dried" for medical mission work. This field is without an equal in South Africa; its benefits have already been tasted, and many long for its re-establishment, and it is a mighty weapon to use against heathenism in experienced hands.

The subject is far too long to discuss in your columns, and I am unable to do so at this time; but should any of your readers feel interested in medical mission work, the little personal experience I possess shall be placed at their disposal. However, I am strongly of opinion that medical mission work should be conducted independently of any ordinary mission station.—I am, Sir, yours truly,

S. CARTWRIGHT REED, M.D., J.P.

Douglas, Herbert, South Africa, March 31st, 1885.

Select.—There is much more laxity as to medical qualifications in the United States than here; but there is a marked tendency to improvement. We cannot speak definitely as to the employment of unqualified assistants.

USE OF THE TRICYCLE.

To the Editor of THE LANCET.

SIR,—May I ask through your columns whether in the experience of those members of the profession who use the tricycle a woman who is pregnant may ride that machine without any untoward results, and up to what period of pregnancy she may continue to ride with safety? The machine used is the "Quadrant," in which the power is gained by a vertical treadling action, so that the employment of the abdominal [illegible] is reduced to a minimum.—I am, Sir, yours faithfully,

May 12th, 1885. A MEMBER OF THE CYCLISTS' TOURING CLUB.

A COLUMBIAN OPINION ON INFANTILE CONVULSIONS.

DR. EVARISTO GARCIA mentions, in the *Revista Médica* of Bogotá, the case of an infant of a *few days* old with severe and persistent convulsions, both tonic and clonic, which he successfully treated with very frequent small doses of bromide of potassium combined with chloral, warm aromatic baths being administered three times a day. He says bromide and chloral are important and valuable drugs in the treatment of infantile diseases, children bearing relatively larger doses of chloral than adults without vomiting or inflammation of the intestinal mucous membrane; they are, too, more susceptible to the hypnotic effects of bromide of potassium, which produces a calm sleep without convulsions or congestions, which at such an age makes opium a difficult remedy to deal with. Although the bromide produces pruritus with a roseolous rash, it causes sleep and calms the patient.

Mr. G. E. Walker.—The paper is marked for insertion. The letter is, we fear, too lengthy for publication—at least at present.

Mr. Dutch.—We are not acquainted with the rules of the Association.

PERMANGANATE OF POTASH IN FUNCTIONAL AMENORRHŒA.

To the Editor of THE LANCET.

SIR,—Having read with much interest a leading article in your journal on the use of permanganate of potash in functional amenorrhœa, and several communications from gentlemen who had tried it, I determined to give the drug a trial on the first opportunity. It was not long before I had one, and with brilliant success.

Miss E. F——, aged seventeen, had menstruated regularly for two years; but about four months ago her catamenia suddenly stopped, owing probably to a moral emotion that she had at the time. Her general health was very satisfactory, and no signs of any organic disease or chlorosis were apparent; but during the periods at which menstruation would have taken place she suffered from headache, loss of appetite, nausea, heaviness in the lower extremities, and sometimes epistaxis. I ordered one grain of permanganate of potash to be taken three times daily in a little sugared water, with the usual hygienic precautions. After being under this treatment for a few days, menstruation reappeared at the proper time without any pain or other suffering.

Believe me, Sir, yours faithfully,

Malta, May 4th, 1885. F. BORG, M.D.

W. M., M.B.—The improvement in hearing seems to have been due to climatic influences, rather than to any surgical interference. This influence appears to have been relied on by those who recommended in turn high latitudes, New Zealand, and a dry climate. In the lining membrane of the middle ear the local change which is present in good hearing on the one hand, and in imperfect hearing on the other, is of so light a character that a variation in climate is frequently sufficient to effect even sudden changes.

Mr. A. G. Levy.—We can only refer our correspondent to our advertising columns.

TRICHLORACETIC ACID NOT A SOPORIFIC.

SOPORIFIC virtues have been ascribed to trichloracetic acid by various writers. L. Hermann shows, in Pflüger's *Archiv*, that it is destitute of any trace of this action, even when injected in large quantities. Its most characteristic action when injected in considerable quantity is the production of paralysis starting from the hinder extremities.

A Sheffield Medical Student.—We are inundated with such specimens as the one sent by our correspondent. The only remedy seems to be to make these *laches* known to the bodies whose diplomas are held by the delinquents.

COCAINE IN HAY FEVER.

To the Editor of THE LANCET.

SIR,—May I, through your columns, ask some of those who are now familiar with the use of cocaine whether they consider it probable that the application of a weak solution to the conjunctiva and the mucous membrane of the nose would, by virtue of its remarkable anæsthetic properties, be likely to prove of benefit to sufferers from hay fever? Before many days the intolerable miseries of this complaint will be again upon us; and if there is a likelihood of this suggestion proving serviceable, it behoves us to give the drug a trial, with the hope of adding another to its numerous virtues. I have no experience in the use of this valuable aid to the oculist, &c., and therefore am unable to say what would be the proportions of a solution strong enough to be of service without causing discomfort by affecting the accommodation of the eye. I am afraid expense would be an obstacle, for, on inquiry, I find that the present price of a 4 per cent. solution of hydrochlorate of cocaine is [illegible] an ounce.

I am, Sir, yours obediently,

Long Stratton, May 13th, 1885. C. A. O[illegible]

TREATMENT OF EPILEPSY BY SIMULO.

To the Editor of THE LANCET.

SIR,—Would any of your readers who have had experience of the treatment of epilepsy by simulo, a plant of the caper family (mentioned in THE LANCET of April 18th, page [illegible]), kindly give me the result, as I have a case in which all the ordinary remedies have failed, and I am anxious to try it.

I am, Sir, yours faithfully,

May 4th, 1885. M.R.C.S.Eng.

Relative Digestibility of Different Kinds of Flesh.

Messrs. R. H. Chittenden and G. W. Cummins, in the *American Chemical Journal*, describe attempts to obtain positive results as to the relative digestibility of the more common edible species of fish, comparing it with that of various kinds of meat. Artificial gastric juice, made with pepsin and hydrochloric acid, was employed, and the following relative figures obtained:—The digestibility of beef, 100; veal, 95; mutton, 92; chicken (light meat), 87; ditto (dark meat), 84; salmon, 92; mackerel, 86; haddock, 82; trout, 78; lobster (young), 88; ditto (large female), 79; ditto (large male), 69; fresh cod, 72. Generally the white flesh is more digestible than the dark, and raw meat than cooked. In all the above experiments, however, the flesh was steam-cooked.

T. M.—Certainly the practice is a dangerous one. Why do so? It is not only good policy, but simply just, to keep close to the letter and spirit of the law. Let the relieving officer be left to perform his proper function. It is not for a medical officer to take the initiative in the matter. No certificate should be signed, except on a magistrate's order, *in the class of cases referred to.*

L.R.C.P., M.R.C.S., 1860, has not enclosed his card.

"MEDICAL PRACTICE IN THE UNITED STATES."

To the Editor of The Lancet.

Sir,—In answer to the inquiry of "Medicus" in The Lancet of April 11th, I take the liberty to say that the qualifications for practice in the United States are regulated by each State. In the Eastern, Middle, and Southern States a diploma from a legally authorised medical school is required, the same to be registered with the clerk of the court. In a few States ten years' practice previous to the passage of any special medical law qualifies. The East affords the best field for practice. Our professional men in law and medicine in search of new locations gravitate westward. In proportion to the population, they stand about one to two between the East and West.—I am, Sir, yours truly,

U. W. Snyder, M.D.

Belmont, Pennsylvania, U.S.A., April 28th, 1885.

Sciatica.—Spencer Thomson's book, "Health Resorts of Britain," might assist our correspondent.

EXAMINATIONS IN THE VOLUNTEER SERVICE.

To the Editor of The Lancet.

Sir,—Will some of our volunteer surgeons who have already passed their examination kindly assist me by saying which are the best books or book to read for the examination in the volunteer service?

I am, Sir, yours truly,

Hull, May 11th, 1885. A Volunteer Surgeon.

Clinical Lectures

ON

SCLERODERMA.

By H. RADCLIFFE CROCKER, M.D., M.R.C.P.,
PHYSICIAN TO THE SKIN DEPARTMENT OF UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

LECTURE II.

CIRCUMSCRIBED AND MIXED SCLERODERMA.

GENTLEMEN,—We will consider to-day the remaining forms of scleroderma. One is diffuse, and is always unsymmetrical; the other is circumscribed, and, though mostly unsymmetrical, is not invariably so. We will discuss first the circumscribed scleroderma, which is more often called morphœa. As this last name is intended to indicate, it generally consists of blotches or patches, but is sometimes in bands. I will relate to you some cases, and show you others, which will illustrate most of the points that make this form so remarkable and distinctive, that it was a long time before its relationship to the other kinds of scleroderma was perceived, and it is doubted even now by some high authorities, such as Kaposi, whether we ought not to consider it a separate disease. It affects the female sex in even greater proportion than the diffuse symmetrical form, and, like it, may affect both children and elderly people; but it is most frequently seen among young and middle-aged adults. Its clinical features appear in the following cases:—

Miss K——, aged thirty, noticed in June, 1877, a white patch with a "bump" in the nape of the neck about three inches long and about an inch and a quarter in width; she does not think that the area of the patch increased up to the time that I saw her in March, 1878, but it projected more; she suffered from frequent "bilious attacks" attended with giddiness, pain, and weight in the chest, with vomiting and diarrhœa, but no headache. She knew of no cause for the lesion, and can give no account of its development. When I saw the patch it measured four inches and a half by one and five-eighths of an inch, but the upper half was much narrower than the lower; it was of a dead-white hue, with marked thickening in the centre and upper part, but at the edge the thickening was only slight, and faded off into the healthy skin, and there was no vascular zone round the patch. On the surface were shallow furrows radiating from the centre towards the circumference—in short, a puckering of the affected integument as if it had contracted; it could only be pinched up with difficulty on account of the thickening, but it was not adherent to the subjacent tissues. The skin felt hard, like rather stiff leather, between the fingers, and at the extreme edge white dots were seen surrounded by healthy skin. The patch was in the middle line, but more on the left side than the right. She was under treatment for some time, and general tonics were given internally and locally. An attempt at continuous galvanic action was made by fastening on the patch a plate of zinc and copper, with a piece of lint wet with salt solution between them. This did no good; indeed, the thickening increased somewhat, and produced more corrugation of the patch by the central contraction; and soon after I lost sight of her for a time, but three years later I saw her again, and she told me that about a year and a half after I had last seen her she had an attack of typhoid fever, and that after that the patch gradually disappeared; its going and coming appeared therefore equally mysterious, but it is not improbable that the friction of the dress at the nape was a determining cause for its position, and that the prolonged horizontal posture from the typhoid fever was the means of sending more blood to the part, and so led to recovery. The position of this patch in the middle line must be borne in mind, as it contrasts with most others which are more laterally placed, and it cannot be ascribed to a special nerve area. The thickening was greater than we usually find, but is present also in another of our cases. Finally, the complete disappearance of the disease in between two or three years after its first onset is to be remembered as probably part of the usual history of such cases if they could always be followed up. Here is another example of this disappearance whilst under observation in which the patches were multiple:—

Joyce M——, aged thirty-eight. Six months before her application to the hospital she noticed white patches appearing on the right thigh and leg without any apparent cause; the top one was and is attended with itching, but there is no symptom with the others. She knows of no cause for them; her general health is not very good; she has several patches of lupus erythematosus on her scalp and face, most of them cicatrised, the result of treatment, and there is some suspicion of marital syphilis. The morphœa patches are thus arranged: one the size of the end of the finger is situated rather to the inner side of the lower third of the thigh; another below this an inch and a half by three-quarters of an inch, with its greater diameter placed transversely; at the back of the thigh, just above the calf, is another patch an inch and a quarter by three-quarters of an inch; still lower on the inner side of the leg, over the tibia, is a slight yellowish discolouration, not clearly defined, and scarcely diagnosable except for the presence of the others; a little lower is another cicatricial-looking patch, which has still less of the typical morphœa aspect. The upper, larger patch has a slight violet zone round it composed of dilated bloodvessels; the others lack this, but the upper patches are of a yellowish-white colour, hard to the touch, but capable of being pinched up, and feeling like a piece of stiff leather. In the course of the year the patches began to disappear, the top patch and the one below the knee becoming thinner and less discoloured, and six months later the patch on the calf disappeared, but the patient ceased to attend before they were all completely gone.

In the following case the nerve distribution of the patches can be distinctly traced:—

Sarah J——, aged seventeen, attended at the East London Hospital for Women and Children on Dec. 8th, having been sent to me by my friend and colleague, Dr. Donkin. She was pale and subject to fainting, remaining insensible for an hour sometimes, and in some of these "faints" had fallen downstairs. She suffers from frequent headache and pain on the left side; has menstruated, but never regularly; never had rheumatic fever; heart normal. About four years ago she noticed some spots on the flexor surface of the left wrist; several appeared about the same time, extending about half-way up the forearm. They were not more than one-eighth of an inch in diameter, and they have gradually got larger by running one into another, and fresh places are appearing. Most of the patches are now raised above the normal skin, with a sharply defined border, but no vascularity around or in the neighbourhood, and the natural lines of the skin are unaltered. The patches can be pinched up as a whole, but not any part of them, and there is a very decided thickening; two or three are slightly pigmented of a fawn colour, but the rest are quite white. There is slightly less sensibility on the patches than round about them, and the patient thinks there is less strength in the affected arm. The patches are distributed as follows: In the right second intercostal space and towards its inner border, an inch to the right of the median line, is a patch half an inch in diameter; in the second left space on the same level, but two inches from the median line, is another; on the inner side of this in the third space is another, and in the same space are two spots three-quarters of an inch in diameter apparently commencing, the skin looking a little yellow and feeling a little thickened. In the axilla at about the second and third spaces is a group, some of which are a quarter of an inch, others are irregular and an inch and a half or more in diameter, running down rather to the back of the arm; towards the inner condyle is an almost continuous chain of patches; and in the same direction, but rather more anteriorly, is another less marked series, beginning about two inches below the inner condyle and reaching down the forearm for about two-thirds. There are a few directly posterior on the upper arm for about three inches; another series, fewer and less prominent, begins three inches below the acromial process and goes straight down to a point two inches above and to the front of the outer condyle; at this point there is a patch an inch by three-quarters of an inch, and the line is continued on to the upper two-fifths of the forearm; between the outer and inner of these two lines is a third, beginning with small ones a quarter of an inch in diameter, in the middle of the upper arm to the elbow, and from there to an inch above the hand; the lower patches are larger, irregular, and pigmented. The vaccination cicatrices are well-marked, with no morphœa in them. The extreme limits of the size of the patches is a quarter of an inch and two inches. In this case you have to observe that the patient was of a neurotic temperament, that the patches were very numerous, that the first ones came in a group and that they have very considerably increased in size from the date of their first appearance, when they were only an eighth of an inch across; then there was slight pigmentation in some of the patches, but this feature is much more developed in a case that I will relate presently. The arrangement of the patches in the intercostal spaces and in lines down the limbs affords a good illustration of nerve influence in the distribution of the disease—a condition not very uncommon as regards the fifth nerve, but less frequently seen, or less easily recognised, in other parts of the body. The marked elevation of the lesions and the absence of the usual vascular zone are also noteworthy features.

Our next case exemplifies fifth nerve distribution:—

Ellen T——, aged ten years, was sent to me by a doctor from Wirksworth. Three months previously a whitish patch appeared on the forehead just to the right of the middle line at the commencement of the hairy scalp; it is now spreading downwards on to the forehead, and measures an inch and a half by half an inch; the upper and lower parts, which are the more recent, are pearly white and thin, while the middle two-thirds are yellowish and thickened, and the skin cannot be pinched up in these parts. The skin is pink for about half an inch beyond the patch, but there is no distinct zone of vessels. On the scalp corresponding to the apex of the occipital bone, and quite in the middle line, another patch is coming an inch by half an inch, oval and slightly yellowish, but the skin is not thickened. In the centre of the cheek is an irregular patch, about an inch and a quarter by two-thirds of an inch, where the skin is very slightly paler than the surrounding parts, but there is no alteration to the touch or when pinched up. The mother says it is more conspicuous sometimes, when the rest of the cheek is red; now it is only just perceptible, and would have escaped notice if attention had not been drawn to it. With a lens the skin is seen to be slightly smoother than the healthy skin. No assignable cause for the patches is discoverable. The patient has never been strong, and there has been no definite illness except three convulsions at long intervals between the ages of three and five years; and there have been none since. She often complains of her legs aching, and easily gets out of breath, but the heart and lungs are healthy. She was only seen once. This distribution in the course of the fifth nerve is much more striking in some cases, several patches not unfrequently lying exactly along the course of distribution of its branches, the domain of the supra-orbital branch being especially frequently favoured. A patch or band will sometimes divide the forehead and anterior half of the scalp exactly in the middle line, as if by the cicatrix of a sword-cut. I will show you the portrait of such a case presently.

The next case exemplifies rapid evolution:—

William M——, aged eleven years, came to the East London Hospital for Children on June 18th, 1877. A month previously a patch the size of half a crown appeared close to the spine on the right side below the level of the angle of the scapula; a few days later a smaller one appeared in the right interscapular region; the large patch began with itching and tingling; and the week before he came to the hospital he complained of pain in it; the pain was constant but with exacerbations. The large patch is the size of the palm with ill-defined edges, so that the patch gradually merges into the surrounding skin, which is naturally dark; the patch is white and looks like a cicatrix, with brown patches *the size of a florin on it; the skin over it has a* leathery feel, and is thicker than the surrounding parts. In the lumbar region over the spine is a white atrophic spot the size of a pea, depressed below the other skin. There is a streaked patch on the left of the spine glistening and slightly scaly, apparently the commencement of another patch. The boy looks perfectly well and ruddy, and has had no previous illness, except measles; he only attended for a short time and could not be afterwards traced. In addition to the rapid evolution the association of a white atrophic spot with the morphœa is interesting here. This has been previously observed, and is not very surprising if my theory of the pathology of morphœa is correct.

The next case is of special interest, because its course has been watched for several years, so that the evolution of the disease could in great part be traced; and through the good nature of the patient the morbid anatomy has been made out for the first time, both in the early and later stages.

L——, aged thirty-nine, widow, first attended at the East London Hospital for Women and Children on March 16th, 1878. Eight months previously she noticed a white patch the size of a threepenny-piece just above the right clavicle. When first seen by myself it had increased to an oval patch an inch and three-quarters by three-quarters of an inch, consisting of two parts, a white slightly thickened parchment-like portion and a thinner and pinkish patchy-looking part, which surrounds three-quarters of the white part. Beyond this large patch is a white atrophic spot the size of a millet seed. On December 1st, 1877, the patch is described as about an inch to the left of the sterno-clavicular region in the same position. Further observation showed the mode of development of the left patch was as follows:—Several small pearly white and slightly depressed spots about one-sixteenth of an inch across developed in groups, the surface round being pinker than the rest of the skin; these evidently atrophic spots enlarged, and subsequently coalesced into patches of variable size. The centre of the spot is smooth, but the border is slightly puckered into radiating lines. In the neighbourhood of these spots the skin is slightly marked with vessels, but when the patch gets larger, dilatation of the vessels round the patch will probably form a pink or violet zone. The older and larger patch increased in size in a similar way, small atrophic spots first forming, enlarging, and then coalescing with the large patch. On December 31st it was noted that both patches had increased since she was last seen in the spring; the right one had grown in all directions, especially at the anterior and posterior ends, and there was one spot on the right border of the sternum. On the left side the spots had increased in size, many being a quarter of an inch or more, but there was no large patch then; all the new patches were of a much more opaque white than before, especially the posterior end of the large patch. There is a peculiar irritation present. The older and larger patch, which had a very irregular outline, measured four inches by two and a half in its greater diameter. The patient was good enough to allow me to excise a portion of the patch some time previously for microscopic examination, and when the patch was much smaller the whole of it was removed, but it recurred, and it would be impossible to say that any had been taken away from its present aspect (1881). In order to ascertain whether the sweat glands were interfered with, pilocarpine was injected under the skin and sweating was produced all round the patch profusely, and the whole of the body was slightly moist, but the patch itself remained quite dry. The patches are always hairless, and the natural wrinkles are obliterated. She is of a nervous, worrying temperament naturally, and this is aggravated by a poor digestion and family troubles, in the shape of an idiot child and the worry of a shop, of which she is proprietress, in a very poor neighbourhood.—Jan. 19th, 1885: The large patch has not increased in size since I saw her four years ago, but its *texture has altered*, and the upper and older three-quarters are evidently recovering to a great extent. The skin is very thin and of various shades, from bright-red to pink-red; parts of it are well-defined from the rest, and the colour is almost entirely due to dilated vessels. The lower three-quarters is still white and parchment-like, *in fact, retains the morphœa aspect*, but is not uniform. At the most extreme part of the posterior border is a thickened area, about half an inch square, of apparently ordinary keloid, on the site where a piece of skin was removed some years ago. Nearer the median line of the neck than the large patch is an irregular group of six morphœa spots, one-sixteenth to a quarter of an inch in diameter. On the left side the corresponding patch has never developed, as it once apparently promised to do; but there is still only an irregular group of white indurated skin patches, half by an eighth of an inch, and arranged in two parallel lines, some half dozen in all. The skin on which they are placed is still somewhat pinker than the rest, but there is no well-defined zone either here or in the larger patch now.

I have no case of my own to offer you in which the disease is in bands, but there is a very good instance of it reported in the *British Medical Journal* of June 7th, 1884, by Mr. Simpson of Lincoln, in which, as a result of, or at all events consecutive to, an injury to the knee of a girl of between two and three years, the skin over the patch became hard, and the induration spread upwards and downwards until it formed a band *along the inner and anterior aspect* of the limb three inches broad at the groin, and an inch at the dorsum of the foot. The skin was pallid, glossy, and irregularly mottled, with yellowish-brown spots, the borders were irregular and of a pink hue, and the contraction of the indurated skin bent the foot up to an angle of thirty degrees with the leg. The case appeared to be getting better when last seen, about four years from the beginning of the disease.

Mr. Hutchinson's case of Louisa O——, aged five years, reported in his Lecture on this subject, is also in point. Some months after having complained that her foot hurt her, a white patch was noticed in front of the instep, and after that spread rapidly, and when seen a year later there was a "long irregular tract extending from the dorsal surface of the two inner toes along the middle of the dorsum of the foot over the front of the instep and up the front of the leg, *and then, diverging* to the outer side of the knee, passed up the outer side of the thigh as far as the middle."

In both these cases an injury seemed to be the exciting factor, and this is corroborated by others. Thus, in Gillette's case[1] the affection followed a blister; in a case of Dr. Hilton Fagge[2] patches were symmetrically *placed in the position* over which the garters were worn; and these cases support my suggestion that a patch on the neck in the first case related *might be due to the friction* of the dress. No doubt there must be a predisposition on the part of the patient; but this is true also for the cases with a definite nerve distribution; for though the nervous system can determine the occurrence and the position of an eruption, and perhaps its extent and severity to some degree, it depends on the individual attacked what kind of lesion will ensue.

A case of Mr. Streatfeild's bears upon this.[3] A man, aged forty-five, had *morphœa confined* to the area of the left fifth nerve, affecting the skin and subcutaneous structures, and in addition he had exostoses of the lower jaw and hard palate of the same side; he had also ulceration of the lower part of the cornea, but this appeared to be due to the hard edge of the sclerosed lid. Another favourite position for morphœa bands is on the breast, perhaps from the friction from the edge of the stays. And here I would observe that the patches are more *superficial than* the bands, and usually affect the skin alone. Do not imagine that I wish to push the theory of injury to the exclusion of nervous influence. There are *so many* cases where the patches are obviously in the course of nerves, that we must assume they have an important influence in this *arrangement*, and probably in the production of this disease. At the same time, I think that local irritation or injury is the probable exciting cause of a certain number of instances, and local causes should therefore be always sought for; while there are a large number of cases for which we can give no satisfactory explanation unless we assume that there is a local vaso-motor or trophic defect.

(To be concluded.)

ON THE

SIGNIFICANCE OF A PECULIAR MURMUR IN RELATION TO THE DIAGNOSIS OF INTRA-THORACIC DISEASES.

BY J. S. BRISTOWE, M.D. LOND.

(Concluded from p. 881.)

CASE 3. *Disease of heart and large vessels at base, with probable communication between an artery and vein.*—Daniel B——, a letter-carrier, thirty-one years of age, came under my care on Jan. 15th, 1885. His health had been good up to about five years ago; he had never had rheumatism or syphilis. About the time just stated he began to suffer from shortness of breath, and this had continued to increase, but it had not until recently prevented him from walking many miles daily in the performance of his duties in a suburban district. On Jan. 1st he complained of feeling cold and shivering, of cough, and of fluttering at the heart; his breath became shorter; and he took to his bed.

The patient is a spare, pale, but fairly healthy-looking man, complaining of pain in the cardiac region, cough, and dyspnœa. Tongue slightly coated; skin cool and moist; temperature normal. On examining the chest, the lungs, excepting for the presence of a little rhonchus, appear to be healthy. Respiration 30. The præcordial dulness is of normal area. The heart's apex beats about half an inch below the nipple and a little to its inner side, and attending each beat there is a fairly well-marked thrill; there is also slight pulsation visible at the inner extremity of the left second interspace, and here also a slight systolic thrill is perceptible. A murmur is audible over the cardiac area and the position of the large vessels; this is loudest and most distinct *over the situation* of the pulmonic valves and pulmonary artery—or, in other words, over the cartilage of the left third rib and corresponding portion of the second interspace. In this region one can hear the first and second sounds of the heart, the latter being somewhat scratchy in quality; but, additionally, there is a loud blowing murmur, beginning with the systolic sound, continued, without obvious change, throughout the whole of *the systolic period, and with some modification* of character (reminding one of a venous hum) through the second sound into the diastolic period, during which it dies away. The murmur is audible over the aortic area and at the apex; but in these situations (as, indeed over the greater part of the cardiac area) the systolic portion of the murmur is alone distinguishable. The murmur is also to be heard distinctly over the whole of the manubrium *of the* sternum, and behind over the apex of the left lung, and in the course of the aorta as low down as the middle of the scapula. The second sound is louder and more scratchy to the right of the sternum than to the left. It is not quite clear whether the murmur at the apex is wholly conducted from the base, or is in part a mitral systolic murmur. The action of the heart is regular but quick (110); the pulses at the wrists are equal, and, as shown by the sphygmograph, of quite normal character. There is no undue pulsation in the vessels of the neck, and no enlargement of veins about the neck or in the thoracic walls. Pupils equal; voice normal. Abdominal organs and kidneys healthy. No anasarca; no enlargement of the ends of the fingers.

The patient was kept in bed and examined carefully from time to time; further examination confirming the general *correctness of the description* given. *But* a few additional phenomena were observed. Among these, the fact that the right pupil was usually somewhat larger than the left; the fact that occasionally he presented slight puffiness of the backs of the hands, more especially of the back of the left hand (this it appeared had often been observed before admission); and the fact that he suffered at times from some aching pain in the region of the heart and left axilla. So long as the patient *remained in* the hospital he continued fairly comfortable and looked fairly well. But he was occasionally kept awake by the thoracic pain and cough, which, however, were never very severe, and improved. There was some difference of opinion with respect to the intra-thoracic murmur. Some of those who examined the patient held that there was a double basic murmur. For my own part, I never saw reason to modify the description of it given above, and I may add that Dr. Gee on one occasion examined the man with me and came to the same conclusion that I had done.

The patient was discharged improved in health, but unchanged as regards the physical signs of disease, on Feb. 24th, 1885.

What is the matter with the patient? My present experience would lead me to believe that he has an intra-thoracic growth of the same kind as the growths in my first case, or that he has some communication between an artery and a vein, or the equivalent of a vein, as in my second case. I do not believe that he has a tumour, for his symptoms have been coming on for years; they are very slowly progressive at the present time, and there are no enlarged glands in the neck, or tumours there or elsewhere, to confirm the diagnosis of intra-thoracic new growth. On the other hand, it does not seem very likely that any communication exists between the aorta and the vena cava or one of the innominate veins, partly because the murmur is loudest at the left second interspace, which is far removed from the normal position of either of these veins, partly because of the total absence of dilated or pulsating veins in the neck, of distended veins in the thoracic walls or arms, and of œdema and congestion of the head and neck. The absolutely healthy quality of the pulse, combined with the situation in which the murmur appears to arise, might suggest disease of the pulmonary artery, and communication between this and some neighbouring vein, such as one of the pulmonary veins. But primary disease of the trunk of the pulmonary artery is excessively rare, and communication between such a diseased artery and a vein is of too improbable occurrence to deserve serious consideration. The most likely explanation seems to be that the patient has an aneurysm of one of the sinuses of Valsalva or of the aorta in the immediate neighbourhood, and that a small communication has become established between this and either the pulmonary artery or the left auricle. The former of these two incidents is the more common and the less serious, and for these reasons the more likely. I may call your attention to a very valuable report on the subject of "Aneurysm of the Aorta opening into the Cavities of the Heart or large Vessels" published by the late Dr. Peacock in vol. xix. of the Transactions of the Pathological Society, which may be usefully studied in connexion with this paper.

---

[1] [illegible]

[2] [illegible]

[3] [illegible]

I add a fourth case, not because it has any relation to the title of my paper; but because it closely resembles in almost all other points the case of Susannah F——. It presents also features of independent interest.

Case 4. *Large aneurysm of ascending aortic arch; compression and obliteration of junction of both innominate veins with cava; great œdema of head and neck and upper part of trunk; suppuration among pectoral muscles, of middle lobe of right lung, and of tissue between œsophagus and left bronchus perforating both tubes; death; necropsy.*—Henry C——, aged forty-five, was admitted under my care on July 7th, 1857. He had had good health up to seven months previously, when he first felt a dull heavy pain in the chest; this gradually increased, and became accompanied by cough with pain in the head; then difficulty of breathing came on, with inability to lie down, especially on the back or right side. Later on he noticed swelling of the neck and upper part of the chest.

On admission he was suffering from orthopnœa, with an occasional troublesome cough, and intra-thoracic pain. His head and neck and upper extremities were much swollen and congested; and the veins in the neck, as well as those in the upper part of the walls of the chest, were distended. The lower part of the trunk and the legs were wholly free from œdema. The heart's action and sounds were healthy. There was some prominence of the upper part of the sternum and adjoining ribs; and there was an area of dulness, several inches in diameter, having the manubrium for its centre. There was no pulsation here; neither was any murmur detectable. No tumours to be felt in the neck, no inequality of the radial pulses, nor any signs of pulmonary disease.

The patient varied a little from day to day as regards his dyspnœa and pain; but in the main he gradually got worse. The congestion and œdema of his head and neck, upper part of the chest and arms, increased considerably, until his aspect was shocking to look at. And towards the close of his life the œdema descended, and involved not only the abdominal walls, but the legs. His dyspnœa was always considerable, and at times distressing. He was unable to lie down, and generally passed his days and nights sitting across a chair with his face to the back and his head resting on his arms, which were supported on the back of the chair. In this position he dozed from time to time. The pain continued more or less severe. There was nothing specially to be noticed as regards the state of his digestive organs. He took food fairly well, and his bowels were pretty regular. There was nothing abnormal in the urine. He died on July 23rd, sitting on the corner of his bed.

Necropsy.—Extreme anasarca of head and neck and front of chest, slight anasarca of feet. The connective tissue and muscles of the front of the chest were highly œdematous, and the muscles occupying the left mammary region were hardened and infiltrated with pus. The sternum was strongly adherent, especially above, to a nearly globular intra-thoracic tumour. This, which measured nearly eight inches in diameter, extended from the top of the sternum above to the cartilages of the fifth rib below, and from an inch outside the junction of the osseous ribs and cartilages on the one side to the corresponding situation on the opposite. The heart was pushed downwards and to the left, and the lungs were displaced laterally and adherent to the tumour. The pleuræ contained about a pint of serum each. A layer of recent lymph lined the anterior half of the left pleura. The lungs were small. The middle lobe of the right was infiltrated with pus, the lower lobe was collapsed. The rest of the right lung and the whole of the left were crepitant. The pericardium was universally and firmly adherent to the heart by old adhesions, which were abundant, œdematous, and consequently very thick. The heart was of ordinary size, if anything rather small, and its valves were healthy. Pharynx and œsophagus for the most part healthy. But the anterior wall of the latter presented a longitudinal slit or ulcer about an inch long, which communicated with a sloughy cavity the size of an almond between it and the left bronchus. Three or four of the cartilaginous rings of this bronchus were partially destroyed, and their denuded extremities hung into the cavity. The mucous membrane of this tube was perforated at two or three points. There was nothing to show how this small abscess-cavity had arisen; but it was evidently the cause of both the œsophageal and bronchial ulceration. Larynx and trachea and (with the above exception) bronchial tubes healthy. The tumour, which extended back almost to the spine, was an aneurysm, with a thick, tough, fibroid capsule, and nearly filled with laminated coagulum. This latter measured from an inch to an inch and a half in thickness. The rest of the cavity was occupied by more recent clot. The aneurysm sprang from the front and sides of the ascending aortic arch, from just above the valves below to the origin of the innominate artery above. The upper and lower margins of the orifice of communication were thick and rounded. The lateral margins were lost in the arterial walls. No part of the aneurysm had any direct connexion with any of the suppurating regions before described. The transverse arch of the aorta was somewhat dilated; and the whole length of the vessel was studded with patches of atheroma. The right vena innominata was distended, and completely blocked up by adherent, decolourised, laminated coagulum; and coagula gradually assuming the characters of recent clot extended to a considerable distance into the veins opening into it. The same was the case with the left innominate and its branches. But this innominate was thicker walled, and the clot filling it was more adherent and denser. Both veins stood up almost perpendicularly from the aneurysm, at a considerable distance from one another, and the proximal parts of both were lost in the aneurysm, and could not be followed either upon or through its walls. The superior cava could be traced upwards from the heart for a distance of two inches, where it gradually blended with the walls of the aneurysm and was lost in them. The upper end was separated by a considerable interval from the lower end of the right innominate, and by four or five inches from the lower end of the left. The abdominal viscera were all healthy.

CASES OF LITHOTOMY IN THE ADULT,

WITH REMARKS.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.,

SURGEON TO THE LONDON HOSPITAL, AND LECTURER ON SURGERY AT THE LONDON HOSPITAL MEDICAL COLLEGE.

(Concluded from page 856.)

Case 2. *Twenty-six small calculi removed by the lateral operation from a man sixty-four years of age; recovery.*—Henry W——, sixty-four, was admitted into the London Hospital under Dr. Langdon Down on March 14th, 1873, and remained on the medical side of the house till May 4th, when he was transferred to my care. The diagnosis card bore the record, "granular kidney, bronchitis, and cystitis." The urine had been alkaline at first, later slightly acid; sp. gr. 1025, and contained mucus and one-eighth of albumen. The patient had been troubled with a cough for many years, worse in the winter than in the summer. He had never had hæmoptysis. He said he had stricture for two or three years. Nevertheless, a full-sized catheter passed easily. He suffered from great pain in the back, preventing sleep.

On May 22nd, having found that there were calculi in the bladder, I passed a lithotrite scoop, seized a calculus, brought away a portion, and tested it. The muroxide test showed that it contained lithic acid. Although the patient had no shivering fit afterwards or other bad symptom, he certainly did not wear the aspect of a case favourable for either lithotomy or lithotrity. He appeared to be an old broken-down man, with bronchitic and emphysematous lungs and damaged kidneys; but I thought he would have the best prospect of recovery if I removed the calculi as speedily as possible. Accordingly, on June 9th I performed the lateral operation on the principle of the median, cutting into the urethra as far as the apex of the prostate, and slightly into the gland, introducing a director, withdrawing the staff and then insinuating my finger into the bladder. I say into the bladder, but in reality I could scarcely reach further than the vesical orifice, owing to the depth of the organ and the great enlargement of the prostatic lobes. In performing the operation I used a curved catheter staff, made for me by Messrs. Krohne and Sesemann, after the model of the ordinary rectangular catheter staff. The calculi were extracted one by one, twenty-six in all. The largest were about the size of marbles, of a buff colour, and marked with facets. There was tolerably free hæmorrhage, chiefly venous, due to congestion of the parts. A tube with a sponge was introduced. A little bleeding following the operation was easily stopped by the pressure of a couple of sponges.

June 10th.—A better night than for some time; pain at meatus, which used to be severe, nearly gone; tongue coated; much flatulence; sickness; thirst. Temperature 99·8°; pulse 120; respiration 30; taken no food; all the water comes through the tube; anxious expresssion; no pain; scrotum and perineum of a blackish colour from blood extravasation.—11th: Very low; passed a very bad night; erysipelas of nose appearing; tongue coated; pulse feeble; takes no food; tube removed; an indiarubber catheter inserted quite easily. Temperature 102°.—12th: Catheter came out and could not be repassed; no vomiting; in much the same condition; takes milk; urine passes through the wound.—13th: Great pain at times; takes egg, milk, and brandy; erysipelas spreading; nose swollen. I passed a catheter into the bladder, and, having drawn off 20 oz. of very offensive purulent urine, washed out the bladder.—14th: Better; less pain; more relish for food; urine drawn off clearer; bladder washed out.—16th: Rather better; takes more nourishment; erysilepas disappearing.—17th: Better; less pain; erysipelas gone.—19th: Better; takes food fairly; half an ounce of very fetid pus drawn off with the catheter; subsequently the urine drawn was clearer.—20th: Much better; takes plenty of nourishment; two teaspoonfuls of urine passed through the urethra. From this time he was convalescent; the wound healed slowly; the bladder was regularly washed out, and at the end of some weeks he left the hospital, cured so far as the lithotomy was concerned. The calculi are in the museum of the College of Surgeons. Like the others, they were analysed by Mr. Taylor; they consist of uric acid upon a minute nucleus of oxalate of lime. The outer surface of the calculi is coated with a thin layer of urate of ammonia.

Remarks.—Lithotomy, as performed in the present case, cannot be regarded as in itself a dangerous operation. With a very limited incision of the prostate, with only slight dilatation of the gland, and without subsequent contusion in the extraction of the calculi, lithotomy is reduced nearly to a simple incision in the urethra, a procedure which can scarcely have a higher rate of mortality than the "catheter fever," which has been stated on high authority to be fatal in 4 or 5 per cent. of the cases. One of the main features of the case was the marked amendment which followed the withdrawal, on the fourth day after the operation, of a pint of purulent and offensive urine and washing out the bladder. The absence of interference with the neck of the bladder left the retentive power of the viscus unimpaired, and the urine accumulating mixed with vesical mucus and pus, and therefore readily decomposing, created irritation, and probably promoted the spread of the facial erysipelas. Two days after the irrigation of the bladder commenced the erysipelas had gone, and the patient's condition had greatly improved. The foregoing two cases are the only instances of multiple calculi in the adult for which I have performed lithotomy. About this period I attended a case of calculous affection recommended to me by my colleague Dr. Meymott Tidy. The patient was a man seventy-six years of age, who could not pass his urine on account of atony of the bladder accompanying the presence of several calculi in the organ. He was in fairly good condition and much better to all appearance than Henry W——, not being confined to bed or suffering from any serious concomitant disorder. The urine was free from albumen. I gave my opinion in favour of an operation, but very naturally before he decided the patient desired to have a consultation, and Sir William Fergusson saw him with Dr. Tidy and myself. Sir William soon satisfied himself as to the presence of multiple calculi, and after he had returned home wrote to me to the effect that he did not consider the stones as the cause of the atony of the bladder, and advised me not to press the patient to consent to an operation. In deference to Sir William's high authority this negative course was pursued. The patient lived four months longer, regaining some power over his bladder before his decease. No post-mortem was made, the patient being a Hebrew. My impression was that he would have been more comfortable and, provided that he had survived the operation (and I see no reason why he should have succumbed), have had a better prospect of prolonging his life if the calculi had been removed. But this was only an impression which I did not feel justified in acting upon in opposition to the view of a surgeon possessing so extended an experience as Sir William Fergusson. This, however, I think I may say, that if I myself at the same age were suffering constant discomfort and pain from the presence of calculi in the bladder, without very pronounced degeneration or disease of the vital organs, I should certainly have them removed either by lithotrity or lithotomy, and I know of no fairer test to apply in the recommendation of an operation of a serious nature than this—viz., "Would you have it performed upon yourself?"

CASE 3. *Calculus in the bladder of a man sixty years of age: lateral lithotomy: recovery.*—James W——, sixty, labourer, was admitted into the London Hospital on April 24th, 1878. Eight months previously he had passed two small pieces of stone about the size of a small pea and quite smooth. When he was at rest the urine remained quite clear, but it became thick after extra work, and he experienced great pain. He attended as out-patient and was sounded, but no calculus was found. On April 27th he was again sounded, and I obtained audible evidence of a calculus. On May 1st there was more pain, of a cramp-like character, accompanied by frequent micturition and sudden stoppages of the urine. For the last three days the urine was passed every twenty minutes or half an hour. At night he passed water every ten minutes. There was considerable pain during the act of micturition and there was blood in the urine. Washing out the bladder with warm water gave relief. On May 23rd I performed lateral lithotomy and removed a mulberry calculus the size of a small walnut. The oozing which occurred after the operation was arrested by subcutaneous injection of ergotine. The patient made an uninterrupted recovery and left the hospital at the end of three weeks.

Remarks.—The duration of the case was not longer than it would have been under the old system of performing lithotrity. As the patient was a healthy man, I believed that he would not run any greater risk from the cutting than the crushing operation; whilst he would be free from the pain which is often occasioned by small fragments of stone which have escaped the grasp of the lithotrite. As in the preceding case, the operation was a urethrotomy, accompanied by a very limited incision of the prostate.

CASE 4. *Calculus in the bladder of a man sixty-eight years of age: lateral lithotomy: recovery.*—James B——, sixty-eight years of age, labourer, was admitted into the London Hospital on Dec. 7th, 1880. He said that he felt quite well till four years ago, when he began to suffer severe pains in the hypogastric and perineal regions, which were of a cutting character and intermittent. Sometimes he did not feel them for several hours or days; they were always worst while he was moving about, obliging him to stop and sit down, when they would pass off. He had always lived in Norfolk (West Bilney, near Lynn) and been a very temperate man, drinking spring water which was clear and pure to the taste. In all respects, save as to the cause of his calculous complaint, he had been healthy. He had a fresh colour, and appeared to be free from organic disease. He had frequent desire to micturate, sometimes every quarter of an hour, attended with severe pain towards the end of micturition. He had not noticed the stream suddenly stop or found it easier to micturate in one position than another. He had never passed any pure blood, but after exertion the urine became very dark. As a rule the urine had been clear and never offensive. On admission it was loaded with mucus.

Immediately on the introduction of a sound into the bladder a calculus was struck lying close to the orifice, From the prolonged impression of contact with the calculus produced when the sound was passed over its surface, I judged that it was of considerable size. A lithotrite was introduced to determine the exact size of the calculus, but it was found to be difficult to seize it, and the further prosecution of the matter was deferred until the patient could be anæsthetised. The patient's consent having been obtained to the performance either of lithotomy or lithotrity, as might be considered best, he was placed under the influence of ether on the afternoon of the 13th, and an attempt was made to inject the bladder, but the water escaped by the side of the catheter and the bladder could not be induced to retain fluid however cautiously injected. The calculus was grasped by the lithotrite and found to exceed considerably an inch in one of its diameters, and from the ringing sound elicited on percussion it was evidently dense and hard. These circumstances, combined with the irritability of the bladder, made me decide upon the performance of lateral lithotomy. A rectangular staff was introduced, and, in the absence of any of my colleagues, was held by Mr. Makeham, one of my dressers. No difficulty was experienced in reaching the bladder; but the viscus being empty, there was no gush of water to carry the calculus within the grasp of the forceps. As soon as the calculus was seized, it was found impossible, without undue force, to extract it through the limited opening made in the prostate. I therefore introduced my left index-finger and cautiously enlarged the opening by incising the prostate on the same side for a quarter of an inch with a probe-pointed knife slid along the finger. The neck of the bladder apparently remained intact. The stone then came out without effort. It was solitary. The patient was the subject of piles, brought on no doubt by the constant straining and frequency of micturition. The parts generally were vascular; and there was some smart hæmorrhage from the superficial branches of the pudic, one of which required ligature. Some oozing from the prostate was soon stopped by the introduction of ice into the wound and into the rectum. The tube was not used; in fact, I now generally dispense with it both in children and adults. The stone was chiefly composed of lithic acid. It was ovoid and flattened, and measured 2⅛ in. in its longest diameter, and nearly 1 in. in thickness. It weighed 1¾ oz. Its surface was slightly nodular and without facets. A hypodermic injection of ergotine frequently used after operations to ensure contraction of small arteries was administered before the patient was sent to bed. *On Dec. 14th* he seemed very well; no hæmorrhage; had a good night, and took his breakfast heartily. Temperature 100·2°.—15th: Going on well; no pain; sleeps well; appetite good. Temperature 99·2°, gradually coming down to normal. Bowels well open, and passes a little urine by the natural passage.—22nd: Has progressed without a bad symptom. Temperature normal. Most of the urine passes through the wound. The patient made a rapid and excellent recovery in every respect, and was able to leave the hospital cured in a few weeks.

Remarks.—Prior to the introduction of "litholapaxy" the foregoing case would have illustrated very well the circumstances under which lithotomy should be preferred to lithotrity. The size of the stone and the extreme irritability of the bladder, which could not be induced to retain any water, would have been the determining points in the case. At the present time it is, perhaps, scarcely possible to fix a decided limit of size at which lithotrity should end and lithotomy begin, the practice of continuous crushing and removal of fragments at one sitting having abolished one of the main objections to the application of lithotrity to large calculi. It was not so much, therefore, the size and hardness of the calculus as the resentment of the bladder which decided a resort to lithotomy as the safer operation for the patient to undergo. The temperate habits of the patient and his healthy appearance led to the belief that his kidneys were free from organic disease and that he would bear the operation well, and the belief was justified by the result. The patient when last heard of (at the beginning of 1884) was in good health.

CASE 5. *Large vesical calculus in a female; vaginal lothotomy; cure.*—Elizabeth B——, aged seventeen, collar dresser, a stout pasty-looking girl, was admitted into the London Hospital on July 3rd, 1883, from the out-patient department. She stated that nine months previously she passed blood in her urine, which dribbled away from her. The dribbling lasted two months and then passed off. About a fortnight before admission she had to pass her urine twelve or fourteen times in the twenty-four hours, sometimes only a tablespoonful at a time. Lately she had not seen blood in her urine.

On admission she complained of frequency of micturition and of pain during the act. She had to strain to pass urine. On examination with the sound a stone of large size was at once detected. The urine was found to be remarkably pale and contained urates, but no phosphates, as a deposit.

On July 25th the patient was anæsthetised and a lithotrite introduced into the bladder, when the great size of the stone became apparent. As it was not easily grasped and as the urethra was not readily dilatable, I decided on removing the stone at once through the vagina. A duck-bill speculum was introduced into the vagina and a grooved staff into the bladder, and an incision was made through the anterior vaginal wall, the wound being enlarged with a blunt-pointed bistoury both upwards and downwards. The stone was then seized with the forceps and with some difficulty extracted, care being necessary to avoid bruising the edges of the wound. After extraction the bladder was washed out and the edges of the incision brought together with five or six silk stitches, some of the stitches being made to include the mucous membrane of the bladder. An S-shaped catheter was retained in the bladder for a few days.

The patient went on very well after the operation till July 28th, when she was found to wet her bed at night. The bladder and vagina were daily washed out, and no fistula was detected by the house surgeon; but on examination on August 11th urine was seen to pass into the vagina from the bladder, and I removed one or two stitches in the middle of the wound, which had become loosened. On the 14th I removed the remainder of the stitches, and perceived that the incision had healed save in the centre, where a small fistulous opening remained. This was cauterised with the nitrate of silver stick. On the 16th it was noted that the urine came through the urethra and there was no incontinence either by day or night. The urine was normal. The patient remained in till the early part of September, gaining in weight and free from discomfort. Before leaving she was examined with the speculum, and the wound was closed in its whole extent. The stone, which was of an oval shape, weighed nearly three ounces, and measured in the long circumference six inches and in the short five inches and a quarter. It was composed externally of a thick layer of phosphates. In the interior, situated excentrically, there are some rings of lithates, *alternating with phosphates, and in the centre* a nucleus, consisting apparently of lithic acid. A peculiarity in the patient's dietary, which might hold a causal relation to the calculus, is mentioned in the notes. She was very partial to pickles of all kinds, and had eaten them largely and almost daily for a long time.

Remarks.—Whilst lithotrity is applicable to the majority of cases of stone in the female there are some cases which, I think, are better treated either by extraction or lithotomy. For small calculi dilatation of the urethra with the finger and extraction with forceps can be carried out without inducing incontinence. Where lithotomy is selected I should certainly give the preference to the vaginal operation, avoiding the urethra altogether. If a clean incision is made and all bruising of the edges of the wound avoided, the wound can be immediately closed after extraction, and no fistula need remain. It is generally recommended that the mucous membrane of the bladder should not be included in passing the stitches. I departed from this recommendation in the present instance without disadvantage.

Finsbury-square, E.C.

SANITARY INSTITUTE OF GREAT BRITAIN. — The exhibition of sanitary apparatus and appliances and articles of domestic use and economy, to be held at Leicester from Sept. 22nd to Oct. 10th in connexion with the eighth autumn congress of the institute, is divided into five classes. The first relates to building materials, construction, and machinery; the second to water-supply and sewerage; the third to heating, lighting, and ventilation; the fourth to personal *hygiene, foods, and disinfectants*; and the fifth to articles of sanitary interest not included in the above classes, such as scientific instruments, books and periodicals, models and drawings, prevention of accidents, respirators and face-guards for unhealthy occupations, fire-preventing appliances, methods for the disposal of the dead, &c.

ON THE

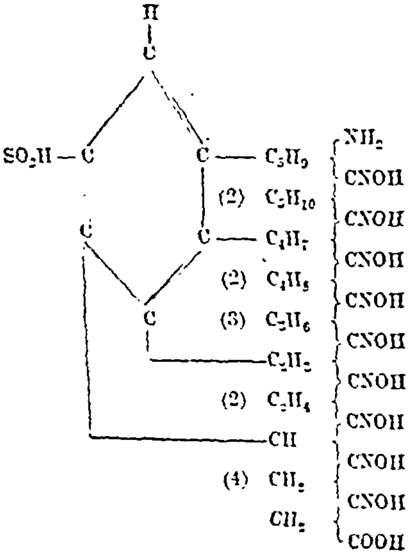
ORIGIN AND FORMATION OF LACTIC ACID, CREATINE, AND UREA IN MUSCULAR TISSUE.[1]

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,
DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE, AND SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

AFTER pointing out that sarco-lactic acid differed from fermentation lactic acid, and might be regarded as a mixture of ethidene and ethene lactic acids, these being obtained by converting ethylic and ethene alcohols into cyanhydrins, and then acting upon them with acids or alkalies, Dr. Latham suggested that the dehydration of the glycines or amido-acids, glycocine, leucine, &c., could give rise to these cyanhydrins—a molecular change taking place in the conversion of $CO.NH_2$ from the dead state to the living, into $CN.OH$—that by dehydration of the glycines generally the following change would take place:—

$$3C_nH_{2n}\left\{\begin{array}{l}NH_2\\COOH\end{array}\right. = \begin{array}{ll} & NH_2\\ C_nH_{2n} & \\ & CN.OH\\ C_nH_{2n} & \\ & CN.OH\\ C_nH_{2n} & \\ & COOH\end{array} +2H_2O$$

Then by dehydrating six molecules of glycocine and three of each of the other glycines in the series up to leucine, together with a sulphur compound and attaching them to a benzene nucleus (taking the formula for tyrosine as an example), we should have a compound represented by the following formula:—



the numbers in the brackets representing the number of times that cyanhydrin is repeated in that group, and the composition of the compound would be $C_{72}H_{112}N_{18}O_{22}S$; which is almost identical with the formula given by Lieberkühn viz., $C_{72}H_{112}N_{18}O_{22}S$.

By hydration of these cyanalcohols the corresponding acid would be formed and ammonia liberated, which, however, combining with the next molecule higher up in the chain, would form a cyanamide. In this way the molecules being detached from the benzene nucleus, we should get the following compound:—

$$\begin{array}{ll} & OH\\ C_2H_4 & \\ & CN.OH\\ CH_2 & \\ & CN.NH_2\\ CH_2 & \\ & CN\end{array}$$

Three different conditions now present themselves: (1) the molecule $CH_2\left\{\begin{array}{l}NH_2\\CN\end{array}\right.$ may become detached, or (2) the molecule $CN.NH_2$ or (3) the larger molecule $\begin{array}{ll} & OH\\ CH_2 & \\ & CN.NH_2\\ CH_2 & \\ & CN\end{array}$ may be separated from the chain. In Case 1 we should have by hydration

$$\begin{array}{ll} & OH\\ C_2H_4 & \\ & CN.OH\\ CH_2 & \\ & CN.NH_2\\ CH_2 & \\ & CN\end{array} + H_2O = \begin{array}{ll} & OH\\ C_2H_4 & \\ & CN.NH_2\\ CH_2 & \\ & CN\end{array} + CH_2\left\{\begin{array}{l}NH_2\\COOH\end{array}\right.$$

and so on, the remaining two molecules by hydration being converted into $CH_2\left\{\begin{array}{l}NH_2\\COOH\end{array}\right.$ glycocine, $C_2H_4\left\{\begin{array}{l}NH_2\\COOH\end{array}\right.$ alanine, and NH_3, which last passes on to form another cyanamide in the chain.

If, on the other hand, the molecule $CN.NH_2$ is detached, we have

$$\begin{array}{ll} & OH\\ C_2H_4 & \\ & CN.OH\\ CH_2 & \\ & CN.NH_2\\ CH_2 & \\ & CN\end{array} = \begin{array}{ll} & OH\\ C_2H_4 & \\ & CN.OH\\ CH_2 & \\ & \\ CH_2 & \\ & CN\end{array} + CN.NH_2$$

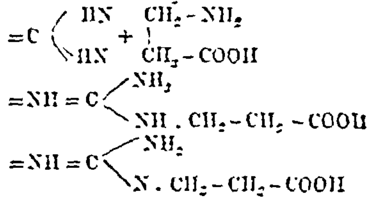
and there is formed the next cyanalcohol in the series $CH_2.CH_2\left\{\begin{array}{l}OH\\CN\end{array}\right.$ or $C_2H_4\left\{\begin{array}{l}OH\\CN\end{array}\right.$, and cyanamide; the latter with water forming urea:

$$CN.NH_2 + H_2O = \underset{\text{urea.}}{CO\left\{\begin{array}{l}NH_2\\NH_2\end{array}\right.}$$

In this way we pass from the lower cyanalcohols to the higher with the formation of urea, the two molecules of CH_2 combining to form C_2H_4. From this and from the other form of $C_2H_4\left\{\begin{array}{l}OH\\CN\end{array}\right.$ higher up in the chain, by hydration, lactic acid would be produced possessing the ordinary characters of sarco-lactic acid. In Case 3 by hydration we should have—

$$\begin{array}{ll} & OH\\ CH_2 & \\ & CN.NH_2\\ CH_2 & \\ & CN\end{array} + H_2O = \begin{array}{ll} & NH_2\\ CH_2 & \\ & CN.NH_2\\ CH_2 & \\ & COOH\end{array}$$

$$= CN.NH_2 + \begin{array}{l}CH_2-NH_2\\ |\\ CH_2-COOH\end{array}$$



the ordinary formula for creatine—and according to this we ought to obtain creatine artificially from ethene alanine. The fact that the cyanalcohols might be transformed into some acid and the different cyanamides, two and three molecules of the latter easily condensing with elimination of ammonia, was referred to as offering some clue to the phenomena of rigor mortis and the coagulation of the blood.

---

[1] Abstract of a paper read before the Cambridge Philosophical Society, May 11th, 1885.

CITY ORTHOPÆDIC HOSPITAL.—The thirty-third anniversary festival in connexion with this institution was held on the 15th inst. The charity was founded in the year 1851, to give free advice and assistance to poor persons of every nation suffering from club-foot and curvature of the spine, and contractions and distortions of the limbs. During nearly thirty-five years of its existence it has relieved 45,548 cases of deformity. The number of patients admitted to treatment during the past year was [illegible].

CASES
ILLUSTRATIVE OF CEREBRAL SURGERY.

By WILLIAM MACEWEN, M.D.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

(*Concluded from p. 883.*)

CASE OF MONOPLEGIA OF LEFT ARM AND LEG DUE TO CORTICAL LESION.

Summary.—Left-sided motor monoplegia of arm and leg, preceded by muscular twitchings and tingling sensations, without loss of sensation, due to syphilitic lesion; cortical lesion in right motor area, superior half of ascending frontal and parietal convolutions, with probable involvement of paracentral lobule; trephining; internal table of osseous disc removed, showing osteophytic deposits; dura mater thickened; plastic membrane-like effusion over anterior and posterior ascending convolutions and bridging fissure of Rolando; resistant portion of brain towards paracentral lobule; incision into brain; escape of grumous fluid with pultaceous particles; marked absence of brain pulsations prior to removal of this matter; slight return after evacuation; exploration of interior of skull; discovery of osteophytic projections on occipital bone; second trephining to remove these; reimplantation of osseous fragments; complete recovery from operation, and power of left arm and leg restored so as to enable patient to walk about and to perform household work.

Case 2.—Mrs. McK——, aged twenty-five years, was admitted into Ward 22 of the Glasgow Royal Infirmary, suffering from left-sided hemiplegia. She had been previously under the care of two physicians, besides having been a patient in the Western and Royal Infirmaries. In the medical wards of the latter institution she had been under the care of Dr. Wood Smith, who had treated her for the hemiplegia by every medicinal means at his disposal without benefit, and who ultimately recommended her to be placed under my care, in the hope that something surgical might be done for her relief. She had a clear history of syphilis of more than four years' standing. The secondary symptoms had evidently been slight. Among other manifestations of the tertiary period was an ulcer situated over the upper part of the occipital bone, principally on the left side. There was a story of an injury over the same quarter, and the patient was inclined to attribute the ulcer to the blow rather than to the disease. For this tertiary affection she had been treated medicinally, with the result of the complete healing of the sores. Eight months after the ulcer on the head had healed, and while she felt herself otherwise in good health, she began to experience a tingling sensation in the muscles of the left arm, and subsequently in those of the left leg, which was occasionally accompanied by slight muscular twitches. These continued for about six weeks, the sensations gradually increasing until numbness supervened, spreading over the affected parts, and taking the place of the tingling sensations. Regarding the word "numbness," the patient used it, though she said that she could feel quite well in these parts, and that at no time had the sensation of touch been impaired. Towards the end of this period the left arm, which had been gradually becoming more feeble, had so far lost its power that she was unable to use it, and a "short time" afterwards she was obliged to go to bed, as she could not stand. Eight weeks from the commencement of these symptoms she had lost all power of the left arm and leg. Three months after the beginning of these symptoms she was admitted into my ward. On examination, the patient was found to have absolute motor paralysis of the arm and leg, accompanied by sufficient rigidity to indicate a slight degree of spastic condition of the muscles. The sensation over the affected limbs was unimpaired. She complained of languor and a general sense of oppression. Her intelligence was dull and her memory defective. Tapping the head gave rise to disagreeable feelings, but there was no specially localised sensations with the exception of a tenderness over the occipital region at the site of the scar left by the tertiary ulcer. It was apparent that there was a lesion or lesions in and confined to the cortical areas controlling the movements of the leg and arm. The absence of anæsthesia in the affected parts from the very beginning of the attack pointed to the lesion being cortical rather than central. According to Charcot and Pitres cortical cerebral monoplegias affecting the arm and leg coincide with lesions in the superior half of the ascending frontal and parietal convolutions. Viewing the pathological conditions which existed here and the clinical history, it was possible that two separate lesions were present acting coincidently, the one on the arm the other on the leg, a short interval of time existing between the initial manifestation of each. In that case, the lesion affecting the power of the arm would involve chiefly the middle of the ascending frontal and to a less extent the corresponding part of the ascending parietal; while the paracentral lobule would be looked to as the seat of the lesion affecting the lower limb. The history showed that the lesion at first induced cerebral irritation, though its true destructive nature was subsequently evinced, and descending degeneration of the motor tracts was imminent, if it had not already set in. The nature of the affection from a pathological standpoint was clearly syphilitic, probably in the form of a gumma.

As the treatment, especially that by counter-irritation, and the prolonged administration of anti-syphilitic remedies, had failed to effect the slightest improvement, it was deemed advisable to have recourse to operative measures. Before trephining was performed, three weeks were permitted to elapse, during which no anti-syphilitic medicines were given, partly with the view of ascertaining whether those formerly exhibited would produce any effect, and partly to avoid obscurity as to the result of the operation. By elevating a large disc of bone so as to expose the greater part of the upper portion of the ascending convolutions it was believed that the lesions affecting the arm and leg could be removed, and at the same time, if the paracentral lobule was involved, it could be reached by making a transverse incision into it through the brain tissue.

Operation, June, 1883.—The hair having been freshly shaven and the scalp thoroughly cleansed, first with soap and water, then with turpentine, and finally with an antiseptic solution, a disc of bone over an inch in diameter was elevated from the right side of the skull, its anterior border touching a point about half an inch behind the auriculo-bregmatic line, while its upper margin reached a point about an inch from the centre of the longitudinal sinus. The internal surface of this disc was rough from osteoplastic formation, some of these irregularities projecting nearly one-sixteenth of an inch beyond the level of the internal table. Round the circumference of this aperture the dura mater was normally adherent to the skull, except towards the posterior part, where it seemed slightly separated from the bone, and where the probe easily passed between the dura mater and the skull for fully two inches, at the extremity of which it met with a similar roughened portion of the internal table of the skull, at the posterior border of the parietal, near the lambdoidal suture. This corresponded internally to the right extremity of the scar left by the former ulcer of the scalp over the upper portion of the occipital region. The dura mater exposed by the elevation of the disc of bone was more opaque than usual, its external surface being somewhat roughened by numerous yellowish indentations, corresponding to the osteoplastic formations. A crucial incision was made into it, and the flaps so formed were gently retracted, when this membrane was seen to be thicker than usual. The appearance of the parts was such as to suggest the probability of the fusion of the arachnoid to the dura mater. A yellowish opaque effusion covered the surface of the brain, obscuring the outline of the convolutions and bridging the fissure of Rolando. On attempting to remove this it was found to be very friable, and it came away in minute portions, and was evidently composed of masses of leucocytes held together by fibrin. On the removal of this effusion it was seen to have covered the middle and upper portion of the ascending frontal, dipping slightly into and covering the fissure of Rolando, as well as the anterior border of the ascending parietal convolution. It was thickest over the upper portion of the ascending frontal and shaded off towards the lower end of the middle third, and while thick over the fissure of Rolando, it formed only a thin layer on the anterior border of the ascending parietal. The surface of the exposed brain was softer than normal, and there were as yet no discernible pulsations. Towards the upper third of the trephine opening a portion of the brain was felt to offer greater resistance to the finger on palpation than the surrounding parts. This sensation proceeded from the interior of the brain, in the direction of the paracentral lobule, a layer of brain tissue intervening between this more resistant structure and the finger. The boundaries of this denser portion could not be well defined, but it was at least the size of a large filbert. An incision was made through the upper portion of the ascending frontal at its posterior margin towards this firm structure, and after cutting into it a quantity (probably about two drachms, though this was not measured) of grumous fluid mingled with minute pultaceous particles quickly escaped; after which the former resistance of the part entirely disappeared, and in its stead the brain surface seemed slightly collapsed, and the cerebral tissue felt softer than usual. The cerebral pulsations, which hitherto had been unobserved, were now barely discernible; they were not so distinct as to be recognised by many of the surgeons round the table. The objects for which the operation was undertaken having been attained, the flaps of the dura mater were replaced, and an aseptic sponge was laid over the opening in the skull. It was, however, considered advisable to elevate a small disc of bone from the posterior portion of the parietal near its junction with the occipital, at the spot where the former exploration revealed the presence of osteophytic deposits, so as to prevent the possibility of future irritation. This was done. The osteophytic irregularities were found to project, for nearly an eighth of an inch, from the normal level of the surface of the internal table. The dura mater, with the exception of slight opacity and indentations corresponding to the osseous irregularities, looked healthy; and the cerebral pulsations were distinctly evident through it. The osteoplastic formations were cut off by the chisel, along with a portion of the internal table of the skull. The remainder of the disc was then divided by the chisel; the pieces of bone were reimplanted and the scalp stitched over them, a decalcified chicken-bone drainage-tube having been placed between the scalp and the skull. The large osseous disc first removed, which since its elevation had been kept in an aseptic sponge, was now divided into small portions, care being first taken to render the internal table of the skull smooth. These portions were reimplanted, space being left between the fragments for drainage. The scalp was then accurately brought together by a few chromic stitches, a small decalcified chicken-bone drainage-tube having been introduced at the lower angle of the wound. The scalp was then dried and powdered with iodoform, except at the parts where the drainage-tubes issued, and which were covered by a small piece of moistened gauze. A eucalyptus gauze dressing was applied over all, and secured by a portion of elastic webbing.

Forty-eight hours after the operation the patient stated that she felt much relieved. The numbness in her left leg had disappeared, though it still remained to a slight extent in her left arm. Four days afterwards the numbness in her left arm had disappeared, and she could move her toes. There was no power of movement in the muscles of the arm or hand. At the end of a week she moved her toes freely and her foot partially. She had also regained the power of moving her fingers to a limited extent, and there was likewise an ability to move the whole arm, principally from the shoulder. At the end of a fortnight she could raise her whole left lower limb from the bed, flex the knee to a slight extent, and move the toes and ankle freely. She flexed and extended the fingers, opened and shut her hand, though the power of grasp was feeble. Her arm she raised to very near the level of the shoulder, though the elbow could neither be flexed nor extended. Three weeks after the operation all these movements had improved, she had greater strength of grasp, and more control over the movements of the lower limb. Her temperature had never been above normal; and there was no stain through the dressings, which had not been touched since the operation. They were, however, removed at the end of this period, and the wounds appeared quite closed. There was only a little blood-stain on the dressing. The extremities of the decalcified drainage-tubes, which had projected slightly beyond the external level of the scalp, were found detached and lying in the dressing. As a precautionary measure, a fresh antiseptic dressing was applied. During the last week the patient had expressed herself as so well that she desired to rise from bed, to which she had hitherto been closely kept and carefully watched. She was, however, advised to remain in bed for two weeks longer. Her diet, which up to this time had been solely milk, was now slightly varied, small quantities of bread and beef-tea being permitted. Six weeks after the operation the dressings were removed from the head, the wounds being found quite firm. The reimplanted bones were firmly attached to the skull. She was permitted to rise from bed, and a more liberal diet was given. Two months after the operation she could walk about unaided, but with a hemiplegic gait, a certain amount of dragging of the left leg, flexion at the knee being still very slight. She could open and shut her hand; but while she could grasp very firmly with her left hand, once she closed the hand on any object it was difficult for her to open it again, unless her attention became diverted. She improved steadily in bodily health and strength until she was able to do ordinary house work, and to walk about easily, though still with a drag of her left lower limb, and to use her left arm when alone, or when not excited, with considerable advantage.

This patient has since reported herself on many occasions at the hospital. The last time she was seen in April, 1885, one year and ten months after the operation. Notwithstanding the fact that since she was dismissed from the hospital she had lived under the most adverse circumstances, her previously affected side was still performing its function as well as formerly. She had walked a mile that day to the hospital, and intended to walk the same distance to her home. She performed her household duties by herself, and stated that she was quite able for them.

There have been seventeen cases under my care in which operations have been performed upon the skull and its contents for the relief of cerebral pressure or other brain lesion. In fourteen trephining was performed and in three elevation of the bones. Out of these seventeen cases, there were three deaths occurring in patients whose prospect of recovery was placed at a bare possibility. In these three, the operation of trephining in no way hastened death: on the contrary, there was reason to believe that it had prolonged life. In eleven of these, the bones which had been elevated were divided and reimplanted. The reimplanted bones in all but two cases succeeded perfectly, and in these two the majority of the fragments lived. In the fourteen cases which recovered there were no untoward symptoms after the operation, the temperature remaining normal throughout, and in almost all the wounds healed without pus production. Hernia cerebri has not followed as a result of any of the operations. It was formed on one occasion at the moment of opening the skull from the acute inflammation which was present in the brain prior to the opening of the skull.

In 1876 I had diagnosed an abscess in Broca's lobe (posterior part of the base of the third left frontal convolution) from the symptoms which were exhibited, and had urged the opening of the abscess, which was, however, negatived by the parents until it was too late to do anything effectively for the relief of the patient. The operation was, however, performed on the dead body, the same steps having been taken as would have been had the operation been performed on the living. The abscess in the brain was opened by the bistoury inserted through the trephine opening, thus proving conclusively the accuracy of the diagnosis, and showing that the operation proposed was the correct surgery of the case. On many subsequent occasions localising symptoms, such as those arising from lesion in the motor area, have been made use of in aiding the diagnosis, and in a number of instances such symptoms have been the only guide to the cerebral lesion. Two of these cases are here given. For the guides which we have received for the localisation of function we are indebted to many observers—Broca, Charcot, Pitres, and Hughlings Jackson on the side of patient clinical research, and Hitzig, Ferrier, and others from the purely physiological side, aided by experiments on animals. Comparatively little advantage has hitherto been taken of these observations as a guide to surgical operations. I had therefore much pleasure in describing to Professor Ferrier, when he visited my wards in Glasgow in the spring of 1884, some cases of the same nature as those here presented, and I was glad that he so soon afterwards had the opportunity of advising and assisting Dr. Hughes Bennett and Mr. Godlee in the case in which the latter removed a tumour from the brain. Mr. Godlee's case unfortunately died from hernia cerebri, and Professor Ferrier asked me some questions on the frequency of hernia cerebri after the operations which I have had. I could have answered that in no case has hernia cerebri been a result of any operation performed by me. But in one instance false hernia cerebri did form at the moment of opening the dura mater. A large mass was extruded, consisting of red blood-corpuscles, leucocytes, and a few pus-corpuscles—a mass on the eve of abscess formation. It is of course clear that since this was protruded at the moment of opening the membranes, this material must have been in existence for some time prior to the operation, and was therefore not the result of the operation. I consider that such a case is of great importance, as showing how false hernia cerebri may form after operations on the brain. False hernia cerebri is supposed by most surgeons to form from a septic condition of the wound, and I quite agree that a septic condition is probably the most frequent cause of false hernia cerebri, but it must be recognised as only *one* of the causes of irritation which set up this condition. We have round most tumours and cerebral lesions a limited area of softening or encephalitis. If such an area exists, it requires to be considered as one of the elements likely to give rise to hernia cerebri, and therefore as one of the risks of the operation. If those observers who have done so much in the way of diagnosing cerebral affections could give precise indications which would enable us not only to say that a tumour or other lesion existed at a certain part of the brain, but also how much and to what degree the brain tissue in the vicinity of this lesion was affected by inflammation, it would enable us to prognosticate whether hernia cerebri would be likely to result from the operation, to anticipate its formation, and to prepare the way for its treatment. It is clear, then, that we have two points to consider: *not* only the lesion (tumour or syphilitic gumma, &c.), but also the amount of localised encephalitis existing at the time. It is further clear that we ought to try to allay this secondary irritation round the tumour or other lesions prior to performing the operation. It may, therefore, be summed up thus:—In certain cases of acute encephalitis involving the surface of the brain, where the inflammatory action is sufficiently far advanced, false hernia cerebri will form, provided an aperture be made through the skull and the membranes to permit of this extrusion. Unless the inflammatory action in the brain substance has taken place to a sufficient extent, false hernia cerebri will not form, even supposing opportunity for extrusion be afforded by an aperture in the external parts. Healthy brain tissue will not be extruded through an aperture in the skull except as the result of violence or pressure exercised from within. Operations on brain tissue, which is not in this state of acute and advanced inflammatory action with blood extravasation, will not produce hernia cerebri, provided that after the operation the brain tissue is not irritated to a sufficient extent to induce this amount of inflammatory action. The chief cause of false hernia cerebri, after intra-cranial operations, is decomposition; and this cause can be prevented by the use of antiseptics. If inflammation in the brain exists at the time of the operation, hernia cerebri may form, notwithstanding the use of antiseptics.

CASE OF FRACTURE OF LARYNX.

By JOHN B. BERRY, M.D., C.M. EDIN.

DURING the afternoon of February 6th I was called to see G. L——, aged twenty-one. He was reclining on a sofa, looking very pale. Extending from the tip of the chin to just above the hyoid bone was a superficial wound. The voice was like that of laryngitis. The prominence of the thyroid cartilage was gone. Placing my hand over the throat and requesting the patient to swallow, I detected unmistakable crepitus of the moving larynx. A more careful examination revealed what felt like a separation of the wings of the thyroid cartilage. The history of the accident was briefly this. About twenty minutes before I saw him he was working a circular saw, and was suddenly struck in the throat with great force by a large piece of wood coming from below upwards. For a few moments he had a hard struggle for breath, but managed to keep from falling by leaning against a bench. Water was brought to him, but he declined it as he feared it would choke him. With the help of two men he walked home, a distance of about 500 yards from his work. Having applied a warm-water dressing to the throat, the patient was put to bed, his head and shoulders being raised. An hour later I saw the patient again in conjunction with Mr. Chaffers, whose help I sought when I saw the case was of such gravity. My diagnosis was confirmed, and seeing the patient was free from urgent symptoms, the breathing being quiet and full and the condition of shock gradually passing off, we considered it best to continue the warm-water dressings and forbid anything being taken by the mouth except ice, leaving word that any change in the breathing should be immediately reported to us. About 1.30 next morning I was called up, as the patient was reported to be choking. After sleeping for about an hour and a half, during which time he breathed rather noisily, he woke up somewhat suddenly and at once began to struggle for breath. When I arrived he was *unconscious*, the eyes were open and fixed, the pupils dilated, the face pale, and the deep spasmodic efforts to breathe were failing. Having sent for Mr. Chaffers, I at once performed laryngotomy. Still no air seemed to enter, and no mucus escaped from the tube. Having satisfied myself the tube was clear and that no blood was obstructing the air-passages near the wound, I enlarged the opening and replaced the tube, with no better result, death taking place after a few more respiratory efforts had been made. Half an hour after death Mr. Chaffers and myself examined the larynx and trachea as well as we could through the operation wound. Besides the separation of the wings of the thyroid oblique lines of fracture were made out on each side, through the wings themselves. Within easy reach of the finger, hanging down the trachea by a mere shred of fibrous tissue was a part of the left wing of the thyroid cartilage itself, the size of a finger-nail, apparently the lower front angle; this was easily removed. I regret no post-mortem was allowed, as I am still in doubt whether to attribute the asphyxia entirely to the one piece of cartilage found, which was not wedged in the trachea, but simply lying flat against the anterior surface, but it may have acted like a valve during inspiratory efforts. During life, I may add, there was no spitting of blood, and after death perfectly white frothy mucus welled up from the throat.

ST. THOMAS'S HOSPITAL.

SARCOMA OF THE KIDNEY; NEPHRECTOMY; CURE.

(Under the care of Mr. CROFT.)

THIS case is a very interesting one, few cases for removal of the kidney for sarcoma being on record. In the Transactions of the Medical and Chirurgical Society, vols. 63 and 64, a list of cases in which the operation had been performed is given by Mr. Barker. Two of these were nearly the same age as the patient who was under the care of Mr. Croft, but in one the disease had existed for two years and a half, and in the other for one year. In each the operation was successful, but in the latter recurrence had taken place in the neighbouring glands eight months after the operation. The prognosis is more favourable in the following case, where the disease had produced symptoms for seventeen days only before operation.

For the following notes we are indebted to Mr. W. J. Staddon, dresser.

T. H——, a boy aged three, was admitted under the care of Mr. Croft on Feb. 3rd, and left cured on March 17th, 1885. The family history was good. The patient had always enjoyed good health, and was apparently quite well until he was noticed to have passed blood with his urine on Jan. 21st of this year. He passed blood again on the 27th and on the 29th. On the 31st the medical attendant noticed swelling in the abdomen.

On admission, the boy was looking very healthy and well nourished. Examination of the abdomen showed a distinct projection on the right side, which on palpation was found to be due to a hard, somewhat elastic, movable tumour, not moving with respiration, which extended into the right loin, the surface of which was marked by large irregular bosses. Above, the free edge of the liver could be felt overlapping it. Dulness extended from the liver to the crest of the ilium, backwards to the spine, and forwards to the middle line, excepting in the position of the ascending colon, where there was resonance. The remainder of the abdomen appeared healthy: there was nothing abnormal in the chest. Urine: sp. gr. 1022, clear, of a light-straw colour, acid, no albumen, no cells, no casts.

Feb. 5th.—The patient was placed under chloroform and examined by Mr. Croft. No stone was detected. There appeared to be a rounded body of small size to the inner side of the growth, possibly an enlarged gland. Urine: sp. gr. 1035; very acid; excess of urea; no sugar.

7th.—The patient having been placed under chloroform, Mr. Croft removed the right kidney. A slightly oblique incision was made between the crest of the ilium and the last rib, about four inches and a half in length, ending anteriorly in the linea semilunaris; this incision was carried down to the peritoneum, when all bleeding points were ligatured. This incision not being large enough to admit of the tumour being extracted, a vertical one was made along the linea semilunaris about four inches in length, opening the peritoneum to the extent of two inches and a half; the tumour was then brought out of the wound as far as the pedicle, which was rather short, would allow. The pedicle was then ligatured in two sections: the first ligature (of silk) included the vessels, and the second ligature (of catgut) was placed on the ureter. After removal of the tumour, the peritoneal cavity, so far as it had been exposed, was sponged out, and the edges of the peritoneum brought together with continuous catgut sutures, after which the skin flaps were brought together with silk, a drainage-tube being placed in the most dependent part. The wound was dressed with oiled-silk protective, iodoform, iodoform gauze, and salicylic wool, gauze bandages being used, and over all a flannel bandage. The carbolic spray was used from the time that the peritoneum was exposed. The patient was very sick towards the end of the operation. The parts removed formed a mass as large as an adult fist. Examination showed the greater part to have been replaced by a large sarcomatous growth, there being only normal renal structure on the circumference of the growth, above and below. The growth was soft, elastic, bulging on section, presenting in parts an almost gelatinous appearance; in others there were small hæmorrhages. The growth projected into the pelvis of the kidney to some extent at one or two points, and also into the renal vein. Later microscopical examination proved the growth of round-celled character.

9th.—Has been going on very well since the operation, having had neither pain nor sickness. Pulse 144; tongue rather dry, slightly furred. Taking milk, tea, and toast. Wound dressed yesterday and looking well.

10th.—Pulse 114; bowels acted after an enema. Wound dressed.

12th.—Pulse 116. He had retention of urine for several hours during the night, and this morning there is some epididymitis on the right side.

15th.—Wound redressed, two stitches removed and the drainage-tube shortened; very little discharge.

22nd.—Pulse 127. Fluctuation having been felt in the right side of the scrotum an incision was made, giving exit to a small quantity of laudable pus. The operation wound was dressed; the granulations were found to be on a level with the skin, excepting where the drainage-tube had been.

March 11th.—Nitrate of silver applied to granulations on the right side. Most of the wounds have healed, as also the wound in the scrotum.

14th.—Got up.

16th.—Wound in right side almost perfectly healed, there being only a few small granulations not quite skinned over; is dressed with zinc ointment. The patient left on the following day, being very lively and looking remarkably well.

The highest temperature after the operation was 102° at 3 A.M. of the morning after the operation. For eight days there was an evening rise, varying from 99·6° to 101·4°; after that it became lower, rising, however, on more than one occasion to over 100°; this was in all probability connected with the epididymitis. The average daily quantity of urine was about 17 oz. after the operation. The patient continues in good health.

Remarks by MR. CROFT.—The rapid recovery in this case was partly due to the fact that the operation was performed before the growth had infiltrated or attached itself to neighbouring structures. Its enucleation did not necessitate [illegible] or the use of any force. Authors on [illegible] have [illegible] laid down any rule for the closing of the peritoneum, [illegible] has been disturbed in the course of the operation. It is worthy of observation in this case that the peritoneal wound was sutured independently of the rest of the wound; thus the cavity was closed against any exudations from the section of the abdominal wall. It would have been impracticable to have treated this according to the rules laid down for closing wounds in the median line. The occurrence of epididymitis was not easy of explanation, as the structural connexion between the parts disturbed or ligatured in the loin is not direct or obvious. Retention of urine came on with the epididymitis, and had not existed before it. It would be interesting to know if other surgeons have met with this complication.

NEWCASTLE-ON-TYNE INFIRMARY.

PRIMARY SARCOMA OF THE RETRO-PERITONEAL GLANDS; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. PHILIPSON.)

J. H——, aged fifty-six, an auctioneer's clerk, was admitted on Nov. 22nd, 1884, complaining of pain in the epigastric region of about six months' duration. His father and a brother died of consumption, and another brother of spinal disease. The patient has had to lift very heavy weights; he has had good food and lodging, and has been fairly temperate; has had three attacks of rheumatic fever. About six months ago he first experienced a dull uneasy sensation in his right side and passing across the lumbar portion of his back. Pain became more decided and was generally worse at night; it came on in paroxysms with intervals of several hours. Gradually the pain became worse and the intervals shorter, till now he has seldom ten minutes' freedom from it. He did his work up to the time of his admission.

When admitted the patient was found to be a man of 5 ft. 7 in. in height, and weighing 9 st. 2 lb. (he used to weigh 10 st. 7 lb.). He is slightly cachectic, and has the appearance of suffering acute pain. The tongue is foul, appetite good, but accompanied by great thirst; the pain rarely crosses the back now, but starts on the right side, crosses the abdomen at the level of the umbilicus, and ends in the left side. The pain is intensified by lying down, but is relieved by sitting up; the greatest relief, however, is got by kneeling before the fire with his elbows resting on a low chair; deep inspiration brings on or aggravates the pain. There is visible pulsation in the epigastric and upper part of the umbilical region; in the right hypochondrium and epigastrium a hard resistant body is felt, reaching in the middle line nearly to the umbilicus, and in the nipple-line about three fingers' breadth past the free edge of the ribs. This body moves with respiration. As far as can be made out, its surface is smooth and its edge regular, and it is not tender, though there is pain on deep pressure. There is no pulsation on the right side of the mass, but on the left the mass rises and falls with the aorta; there is no expansile pulsation. There is continuous dulness from the seventh rib downwards to the edge of the mass. At the apex of the left lung there are distinct signs of consolidation and softening.

December 5th.—Has lost 1 lb. since admission. The pain has become so bad as to necessitate injections of morphia. Temperature varies between 99° and 102° F.

31st.—Is still emaciating. Does not complain so much of pain, but shows decided dementia.

January 24th.—Death.

Post-mortem examination.—The liver extends downwards as felt during life. Its surface is smooth, except on the under side, where there are two nodules about the size of peas. The anterior margin is unusually thin and covers a tumour about the size of the fœtal head lying on the spine. This tumour is evidently glandular, and has the pancreas attached to its left side, in front of it the pylorus and four or five inches of the duodenum, and behind it the aorta. The outline of the tumour is fairly regular, but with globular projections at parts. On section it is pretty firm, but with soft portions here and there. On microscopic examination it proved to be a spindle-celled sarcoma. Lungs: The left apex contained some tubercular deposits and small cavities, while the right had a slight tubercular deposit. Heart: Mitral orifice narrowed and curtains thickened. Brain: Considerable amount of subarachnoid fluid. Kidneys: Normal. No other deposits besides the two on the under surface of the liver.

Remarks by DR. PHILIPSON.—The chief interest of this case was in the differential diagnosis of a tumour situated in front of the abdominal aorta, from aneurysm. The non-existence of aneurysm was inferred from the absence of bruit in the left vertebral groove, and its pulsation being non-expansile. The existence of cachexia was in favour of malignant disease; the age of the patient strengthened this supposition; the smoothness of the surface of the liver and its uniform edge indicated that the swelling was glandular, rather than associated with that organ. Another point of interest was the coexistence of malignant disease and tubercle, cancer and tubercle being regarded as antagonistic one to the other. The nodules on the under surface of the liver were regarded as secondary, or consequential on the glandular condition; primary cancer of the glands being rare, while secondary cancer is not uncommon.

OPHTHALMOLOGICAL SOCIETY.

Ciliary Nerves in Certain Diseases of the Eye.—Spontaneous Disappearance of Diabetic Cataract.—Nævus of Choroid.—Reflex Ophthalmitis.—Periodic Paralysis of Third Nerve.—Coloboma.—Rupture of Eyeball.

AN ordinary meeting of this Society was held on May 14th, Mr. Jonathan Hutchinson, F.R.S., President, in the chair.

The PRESIDENT intimated that the Local Government Board had consented to receive a deputation from the Ophthalmological Society on the subject of the prevention of blindness from ophthalmia neonatorum.

Dr. BRAILEY read a paper on the Condition of the Ciliary Nerves in Certain Diseases of the Eye. Examinations in ninety cases of the long ciliary nerves, usually of both the inner and outer sides, by sections taken at right angles to their course in the sclerotic, showed the following results. It must be remarked that, being cases of excision for disease, the morbid process had been in every case severe, and in most of considerable standing. In primary glaucoma (thirteen cases) the nerve might be perfectly normal, but in about 22 per cent. there were indications of neuritis, the changes being, however, usually so slight as not to be incontestable. In a larger proportion (50 per cent.) the nerves were swollen, their axis cylinders being large and indistinct, or not visible at all. It was observable also that the average size of these nerves in eyes with glaucoma, whether primary or secondary, was considerably (almost 50 per cent.) beyond that associated with normal tension. Probably this enlargement was due to swelling of the nerve fibrils, as it was found even where the microscopical structure appeared to be quite normal. It produced considerable absorption of the sclerotic through which the nerve passed, so that this condition was indicated, especially in the case of the nerve of the inner side, by a wide dark-bluish streak corresponding to the course of the nerve. In eyes exciting sympathetic disease the nerve itself was usually normal in structure, though it might show slight traces of neuritis. But inflammation round the artery and nerve, more marked round the former, was found in the majority of cases (85 per cent.). In the sympathetically affected eye it was also found, though not quite so commonly (66 per cent.). He had, however, but three cases of sympathetically produced inflammation to examine. In uveitis serosa—independent, however, of any relation to sympathetic disease—inflammation round the artery and nerve also occurred, spreading evidently from the former to the latter. In the five well-marked cases of suppurative panophthalmitis that had been examined, the condition was similar to that above remarked as found in eyes exciting sympathetic disease, except that the inflammation around the artery and nerve was well marked in every case. In other conditions, such as iritis and irido-choroiditis of various origin, the condition varied, inflammation in and around the artery and nerve being occasionally found, though far more often absent. Two cases may be particularised: one, a non-suppurative iritis occurring after an iridectomy preliminary to cataract extraction; the other, with changes like those of progressive myopia—viz., disseminated choroiditis at the posterior pole and posterior staphyloma after leucoma adhærens. In each of them there was round the artery much inflammation, which had extended into the corresponding half of the nerve. It was inferred from the above observations that inflammation of the ciliary nerves was not the means by which sympathetic disease was transmitted; also that inflammation round the nerves and their companion arteries was equally ineffective in this case, as it occurred at least as strikingly and as commonly in suppurating eyes. The corneal anæsthesia found in absolute glaucoma was explained by the degeneration of the elements of the nerve, which, together with the other changes noted in this disease, appeared to be secondary to the mechanical pressure upon them.—Mr. NETTLESHIP remarked that serous iritis was not recognised as due to sympathetic irritation. He asked what clinical evidence there was in Dr. Brailey's possession. Referring to cases of episcleritis about the front of the eye, he would like to know whether the inflammation extended along the outer surface of the sclerotic so as to involve the optic nerve and structures at the posterior part of the globe.

Mr. NETTLESHIP read a note on the Spontaneous Disappearance of Diabetic Cataract. So far as his literary researches went he had found that cases of the kind were very rare. Two cases were detailed in Dr. J. Seegen's work on Diabetes Mellitus. Seegen's first case was that of a man aged thirty-nine, who in July, 1863, about six months after the appearance of diabetes, noticed that his sight began to fail; the lenses were cataractous and hazy. Under treatment at Carlsbad the lenses cleared; the quantity of urine was reduced to one-half, but the percentage of sugar remained the same. In the spring of 1865 the lens again became opaque. The second case was that of a woman aged fifty-five, who was first seen in the autumn of 1867, soon after which the sight began to fail and became misty; she was treated for diabetes in February, 1868, and whilst under treatment the lenses became clear again. Dr. Tannahill's case was that of a coal-miner, who was seen when in prison. He had suffered from diabetes for eleventh months; both lenses were opaque throughout, the left more than the right. He was put on the ordinary diabetic diet, and had two grains of opium daily. Whilst under treatment his sight began to improve, the opaque lenses gradually cleared, and on inspection when he was discharged from prison no trace of cataract remained. No satisfactory explanation had yet been offered as the cause of diabetic cataract. The view that the lens contained sugar was a possible explanation, but the idea of a permanent degeneration was not borne out by the facts just narrated; moreover, there was a reappearance of the cataract in one case. The abstraction of water from the lens owing to an increased density of the blood or fluids surrounding the lens was a likely explanation.—Mr. HUTCHINSON said that congenital cataracts in young rabbits sometimes cleared up.

Mr. J. B. LAWFORD read notes of a case of Nævus of the Choroid. The patient was a girl aged eight, who was brought to the hospital on account of pain in the left eye following a blow. The mother did not know how long the eye had been blind. There was a capillary nævus of the left side of the face from the forehead to the chin. There were no nævi elsewhere. The left eyelids were involved, and presented a slightly puffy appearance. The right eye was normal. The conjunctiva of the left eye was normal. The lens was opaque and yellow. There was no perception of light. The tension was + 2. The left eye was excised. On examination, the choroid surrounding the optic disc, and for a distance of 5 mm. to 7 mm. from its margin, was thickened (·5 mm. to 1 mm.), and spongy in appearance. Under the microscope this area was seen to be channelled throughout with vascular spaces of varying size, whose walls were formed only by the choroidal tissue. A few dilated capillaries were also visible. Beyond the limits of the nævus the choroid was normal. There was an infundibular detachment of the retina. The lens was shrunken and its fibres much disorganised. The iris was atrophied and adherent to the cornea at the periphery.

Mr. SIMEON SNELL read the notes of a case of a Recurrent Paralysis of the Third Nerve associated with attacks of Migraine. The patient, a little girl aged eight, first came under observation in Nov. 1883. A note made then states: "There is complete ptosis on the left side, with divergence of the eye and general paralysis of the third nerve; fundus oculi normal; refraction hypermetropic, about 1·5 D." It was ascertained that she had had a failing of the left eye since cutting her "eye teeth," at eighteen months of age; since this time she has suffered from attacks of pain in the head and sickness, and at these periods the eye has closed, and after the subsidence of head symptoms, it commenced to open, but only very gradually became widely so again. These attacks have recurred about every six months. The severe part of one of these illnesses had just passed when she was first seen. Another attack came on in July, 1884, and the affection of the eye gradually passed away, as it had done before, and the condition was just as that described below. On Jan. 20th, 1885, she appeared at the infirmary with commencing drooping of eyelid; it began the day before. Next day the condition was characteristic of migrane, pain confined chiefly to the left side and over the left eyebrow. Ptosis was complete, and palsy of the other muscles supplied by the third nerve; the pupil was a little dilated, and did not act to light or accommodation. Recovery gradually took place in the ocular symptoms. On April 30th the eye was fairly wide open, but not quite so widely as on the sound side; there was divergence, but on effort a good deal of power of convergence; and movements upwards and downwards were extremely slight. The pupil was about the same size as the right, and acted very slightly to light or accommodation. V. (corrected) $=\frac{16}{200}$, and J. 16. There is a distinct neurotic history on both parents' side.—Mr. ERNEST CLARK had seen a somewhat similar case in a girl aged twelve. The attacks were preceded by vomiting and constipation, and attended with pain over the left eyebrow. The sight of the eye was dim. The pupil was slightly dilated; there was external strabismus and slight ptosis, which lasted a few days; the dilatation of the pupil lasted longer. The attack came on every six weeks. The teeth were very bad.—Dr. ORMEROD had also seen a case of recurrent paralysis in an elderly woman; the left eye squinted outwards. Some pain was experienced along the course of the supra-orbital nerve. There was nothing to suggest megrim. These attacks were not so transitory, and lasted two or three months. The first attack was apparently caused by shock on hearing of the death of a sister, and the second by fright at seeing a boy with facial palsy. The Argyll Robertson phenomenon was present, but there was no loss of knee-jerk. He said that Thomsen of Berlin had put on record a case which followed some shock to the nervous system in an epileptic patient; the field of vision was contracted, and this was said to be proportional to the degree of paralysis of the third nerve.—Dr. BEEVOR had seen a similar instance in which exposure to cold winds were assigned as the cause.

Mr. W. H. JESSOP showed a child, aged eight, who had suffered a blow on the eyeball from a fall on a bed post, which was followed by Compound Rupture of the Eyeball in February, 1884. The chief interest of the case was the rapid and complete recovery with useful vision. The rupture in the sclerotic was three or four lines in length, but that in the conjunctiva was large and needed three sutures.

Mr. W. H. JESSOP also showed a case of Posterior Coloboma of the Choroid in both Eyes on the temporal side of the disc. The lens on both sides contained striæ.

Mr. M. MCHARDY showed a woman aged fifty-four who presented a small, globular, dark, red Tumour in the Ciliary Region in the outer segment; a larger and similar growth had been removed in July, 1884. Also a girl, aged sixteen, in whom there was a great Development of Fat in the Upper Eyelids causing much deformity. He had excised an elliptical piece of the upper lid and a large mass of adipose tissue, this afforded some relief.—The PRESIDENT asked whether the first case was regarded as one of melanosis.—Mr. NETTLESHIP inquired how deep the incision went in the removal of the portion of skin; was the layer of muscular fibres cut away? He suggested that the fat might have been of orbital origin. He had seen cases in young women and one in a boy; in one case he had removed a fold of skin twice, but no fat escaped.—Mr. MCHARDY replied that he took care in removing the skin not to cut deeply; he used a pair of "sickle" scissors and removed the skin much in the same way as would be done in the operation of removal of skin for transplantation.

Mr. JONATHAN HUTCHINSON read a paper on the Pathology of Reflex Ophthalmitis. Seven years ago, in some lectures delivered at the Royal College of Surgeons, he treated of the influence of the nervous system in the production of disease. In these lectures he maintained the view that the nerves did not initiate disease by any exercise of their functional power. He maintained that the inflammation actually spread along the nerve filaments. This notion got rid of any suggestion of trophic power in nerves. He now argued that reflex ophthalmitis had nothing to do with the nervous system, for he suspected the circulatory fluids rather than the nerves were the means by which the secondary lesions were originated. The mode of spread or the multiplication of inflammations, malignant diseases, and the like, he explained on the theory of the absorption into the circulation of certain elements derived from the original seat of disease. These elements only produced lesions in those tissues which were practically similar to the tissues in which the original lesion existed. It was another case of selective affinity. So that inflammation was set up in certain parts to the possible exclusion of other parts. In multiple periostitis, for example, the primary lesion was followed by other lesions exactly similar. The lesions never began simultaneously; there was no structural continuity between one periostitis and another, neither by the lymphatics or the nerves. He believed that certain elements were shed into the blood-current, and induced similar inflammations in similar tissues; if a long bone were first affected it was a long bone that suffered secondarily. He would apply similar reasoning to the case of the eye. The elements were first given off from the ocular inflammation and circulated in the blood, and then picked out precisely similar tissues in the other eye as the seat of their selective inflammatory action. It was an example of emigration in which the emigrant, cast off from home, settled down and colonised in parts where the conditions were similar to those which he had left. He considered that such a theory would explain the very exact symmetry of reflex ophthalmitis and other related conditions. The theory held good, not only for traumatic diseases, but for other forms of acute inflammation, such as pneumonia and the like. A view closely analogous, though not actually identical, with this had been propounded by R. Berlin in Volkmann's *Archiv.* for 1880, though Mr. Hutchinson became acquainted with Berlin's views after his own theory had been formed, and as the result of Mr. Nettleship's literary researches specially made with a view to find out whether such a view as Mr. Hutchinson's had been previously formulated. Berlin regarded the infecting elements as parasitic, but Mr. Hutchinson asserted nothing as to the nature of the infecting element. Berlin thought that the smallness of the capillaries in the eye and the influence of light were some of the similar conditions which led to the development of the secondary ophthalmitis in a given case, but Mr. Hutchinson thought that the similarity of the tissues should be regarded as the reason why the secondary inflammation should develop in the opposite eye. Dr. Fitzgerald occupied the chair during the reading of this paper, the discussion of which was adjourned to the next meeting.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, May 6th, Dr. J. B. Potter, President, in the chair.

The following specimens were shown:—(1) Fœtus, showing numerous Deformities of the Limbs; (2) Living child, showing Absence of Lower Two-thirds of Left Forearm and Hand; (3) Two cases of Imperforate Rectum in New-born Children (Dr. Horrocks); (4) Double Pyosalpinx from a woman who died from perforation of the stomach by an ulcer—the pyosalpinx had caused no special symptoms (Mr. Malins).

Dr. MATTHEWS DUNCAN read a paper on the Ulceration of Lupus of the Female Generative Organs, including Perforations, Pits, and Excavations. Ulceration is not an essential part of lupus. Some ulcerations are to be regarded rather as excoriations than as lupus ulcers; generally ulceration is accompanied by hypertrophy. The hypertrophied parts are not specially liable to ulceration. The ulceration may affect the hip or thigh, or any part of the genital organs, external or internal, also the bladder and rectum. The ulceration is generally not sensitive. There may be one or many ulcers. Lupus minimus is characterised by small ulcerations. The skin, mucous membranes, and subcutaneous cellular tissue are the parts chiefly affected; but any structure (except bone) may be destroyed. Sometimes the skin is chiefly affected; sometimes the subcutaneous cellular tissue. The ulceration sometimes produces pit-like cavities; sometimes producing great excavations; sometimes perforating, producing fenestræ or fistulæ; the peritoneum may be perforated. The ulceration is not accompanied by sloughing. The ulcers may heal in whole or in part. Ulcers, the result of wounds of the hypertrophied parts, heal favourably. A specimen from the London Hospital (lent by Dr. Herman) was shown of Dilated Uterine Cavity with Perforating Ulceration.—Dr. HORROCKS mentioned a case under his care in Guy's Hospital, which he had observed for nearly two years. The patient was a single woman, never pregnant. Her complaint was pain in the pudendum and scalding on micturition. Small ulcers occupied the base of the hymen and fossa navicularis. There was no enlargement of the glands, and no history of sore-throat, but, on the suspicion of syphilis, mercury was given internally, and lotio nigra applied externally. No improvement resulting, caustics of various kinds were used, but pain persisted and no improvement followed. The hymen was apparently entirely eaten away, and along the line of its attachment were small red nodules, with a few tiny ulcers. The nodules were very different from carunculæ myrtiformes; there were no lineæ gravidarum, and the cervix was nulliparous. The tubercles were then removed by scraping with a sharp curette and by cutting away with the scissors. The bleeding was so free that one or two vessels had to be tied. Dr. Horrocks asked Dr. Duncan what was his experience of scraping, and what was the best mode of treatment.—Dr. GANDY asked whether there was any fetid odour or other characteristic discharge; whether he could explain the profuse hæmorrhage with so little physical evidence of disease. He related a case in a patient aged thirty-five, in fairly good health, who was suddenly seized with very profuse bleeding which was arrested by subcutaneous ligature. No cause for the bleeding could be discovered, and it now occurred to him that the case might be one of lupus. There was always pain on coitus, but there had not, so far as he knew, been any return of the bleeding.—Dr. CHAMPNEYS asked Dr. Duncan (1) on what grounds these very different affections were included under the same name; (2) why they were called lupus when the microscopists pronounced the appearances to be unlike those of lupus; (3) what these diseases were called before they received the name of lupus.—Dr. MATTHEWS DUNCAN replied that he used the term lupus because others did so. West in his "Diseases of Women" (one of the earliest English notices) used this term. Esthiomene was an awkward word. Lupus expressed the great eroding character of the disease; it included ulcerations, inflammations, hypertrophies, variously combined, and which were not cancerous, not epitheliomatous, not syphilitic. It might turn out that several diseases were included in this comprehensive term. At present they were combined for description on account of their apparent similarity. They were far from being as uncommon as was supposed.

Mr. WILLIAM DAY (Norwich) read a case of Uterine Fibroid complicating Labour and treated by Enucleation. The tumour itself presented, and above the tumour a breech. The size of the tumour and its immobility precluded the possibility of delivery while it was *in situ*. After separating its connexions to a great extent, and thereby attaining greater mobility of the tumour, delivery was effected by the feet, the remaining attachments were severed and the tumour removed. It weighed three pounds and a quarter, was a soft fibroid, and would nearly have filled an ordinary tall hat. A successful case of enucleation of a large fibroid immediately after parturition induced Mr. Day to adopt this treatment. The patient lived for twenty-eight hours after delivery. The child still survives.—Dr. BRAXTON HICKS reminded the Society of a case which he had read before it some years ago, in which he divided the capsule by a bistoury vertically, and enucleated the tumour from its capsule with complete ease and success. This he thought best in the case of sessile or embedded fibroids. He called attention to the work of Dr. Chalibazian on the fibrous tumours of the neck of the womb in pregnancy and labour, to a paper by Dr. Mundé of New York, and to a case of Dr. Fry, in THE LANCET for 1884. He thought that, where delivery was urgent, the general opinion was in favour of enucleating the sessile forms from their capsule, which, in all the cases reported, was not a difficult operation.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The annual meeting of the Irish Branch of this Association will be held in the Royal College of Surgeons, Dublin, on Tuesday, June 2nd. The chair will be taken at noon by the President, Deputy Surgeon-General F. L. G. Gunn. The meeting will be open to all members of the medical profession.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, MAY 14TH.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

THE adjourned debate on Dr. Humphry's motion was resumed.

Dr. HUMPHRY asked permission to substitute for his motion the following: "That the examinations in general education conducted by universities be accepted as heretofore, but that if in any of these examinations the subject of elementary mechanics is not included, a knowledge of that subject should be required at a separate preliminary examination."

Dr. STRUTHERS said if the motion were so altered, he should be willing, if permitted, to withdraw his amendment.

The permission of the Council for the proposed substitution and withdrawal having been given,

Mr. MACNAMARA said he regretted that the Council had laid down such minute regulations in regard to general education, and had endeavoured to press them upon the universities. Dr. Haughton and the provost of Trinity College, Dublin, knew more on the subject of elementary mechanics and the best mode of teaching it than all the Council put together; and it was absurd to endeavour to impose upon the University another method of instruction or examination. They would, if the Council persisted, pursue the even tenour of their way, and the Council could not refuse to register the qualification obtained. He hoped the Council would not put itself in antagonism with the great universities. It was absurd to try to teach Oxford the best mode of teaching and examining in English. All details of the kind should be left to the great teaching bodies themselves.

Dr. PETTIGREW supported the motion.

Mr. MARSHALL said he retained his opinion as to the importance of English as a subject of education; but if the universities thought that they could secure a proper examination in the subject in a collateral way he would not recommend the Council to interfere with them. They had, he thought, complete liberty to examine in English as they liked. He did not approve of the method adopted by the University of Oxford, but he would not interfere with their freedom of action. He suggested that the first part of the motion be omitted—viz., "That the examinations in general education conducted by universities be accepted as heretofore," believing that it was quite unnecessary.

Dr. STORRAR said that the universities had a right to adopt their own methods of teaching and examining in general education; and that the Council ought not to endeavour to draw the bow too tightly, or seek to use a mandatory power, but rather be content with exercising moral suasion. As to the teaching of English, it was difficult to get the older universities to take up English as a separate study; but at the University of London the examination in English was regarded as one of the most difficult of any, and the subject was one of the best as an instrument of education.

After some remarks from Dr. PETTIGREW, Dr. STRUTHERS, and Dr. BANKS,

Dr. HAUGHTON said he objected to Dr. Humphry's motion. The existing state of things brought about by the action of the Council last year had left the Universities of Oxford, Cambridge, and Dublin frying in their own juice: Dr. Humphry's motion, however, took Oxford and Cambridge out of the frying-pan, and left Dublin in it; he therefore strongly opposed it.

Dr. HUMPHRY having replied,

Dr. HAUGHTON moved as an amendment that the word "preliminary" be omitted from the resolution.

Dr. BANKS seconded the amendment.

Mr. SIMON contended that if the word "preliminary" were omitted the motion would be mere waste paper. If there were anything special in the case of the examination at Trinity College it might be met by a proviso.

Dr. HAUGHTON said if "elementary mechanics" was not to be regarded as including statistics, dynamics, and hydrostatics, he would undertake that there should be an elemen-

-tary examination of students before registration at the Dublin University; but he could not undertake that the examination should cover the whole ground of fluids and solids. If his offer were accepted, he could vote for the motion, not otherwise.

Mr. SIMON said that the regulations of the Council would not permit of a definition of elementary mechanics which did not include fluids as well as solids.

Dr. HAUGHTON's amendment was then put and negatived, and the original motion was carried by fourteen votes against four.

Dr. HUMPHRY said he had received a reply from the Cambridge University stating that Ebenezer Bryceson (as to whom he had been requested to inquire whether he had taken the degree of M.B.) had only taken the degrees of B.A. and M.A.

Dr. QUAIN moved the reception of the following report of the Pharmacopœia Committee:—

"The Pharmacopœia Committee have to report to the Council that the duty assigned to them has been so far completed as to enable them to lay on the table a revised copy of the New Pharmacopœia. The Committee recommend that, with a view to the publication of the work now completed, the course adopted by the Council, when the Pharmacopœia of 1867 was published, be now followed. On this subject the Council passed the following resolution on May 26th, 1866: 'That as soon as the proof of the new edition of the Pharmacopœia is ready a copy of it be sent to each member of the Council, with instructions that he will, within one month, return it to the secretary of the Pharmacopœia Committee, with such observations as he shall see fit to make thereon, to be submitted to the Pharmacopœia Committee; and that the Pharmacopœia Committee shall, after due consideration of such observations, hand over the proof, when finally approved, to the Executive Committee for publication.' Should the Council approve of the recommendation of the Committee, they suggest that the Council now adopt the resolution passed on May 26th, 1866, substituting the word 'chairman' in line 4 for 'secretary,' and adding 'sub' before 'committee' in line 6 of the above-quoted resolution. A copy of the completed work will be forwarded within a very few days to the members of the Council for their approval. The Committee cannot conclude their report on the completion of the Pharmacopœia without offering their testimony to the great care, the scientific skill, and the assiduity with which the editors of the work—Professors Redwood, Bentley, and Attfield, and others—have performed their duties."

Dr. QUAIN said that a copy of the Pharmacopœia would be sent to each member of the Council for suggestions before the work was finally issued. It would be a little larger than the previous edition, and would contain about a hundred more pages, but he hoped that the price would not be increased, as no charge would be made beyond the mere expense of production. No effort had been spared to make the work as perfect as possible. Its issue to the public might, he thought, be left with the Executive and the Pharmacopœia Committees, but if any grave question should arise steps could be taken if necessary to consult the Council.

Dr. STORRAR seconded the motion.

Mr. MACNAMARA said he had devoted a great deal of time to materia medica, and could appreciate the labours of the Pharmacopœia Committee. He was well aware of the great zeal and ability, and the great amount of time, that Dr. Quain had brought to bear in supervising the Pharmacopœia, and he begged to move: "That the warm thanks of the President and members of the Medical Council are eminently due, and are hereby tendered to Dr. Quain, chairman of the Pharmacopœia Committee, for his invaluable services in supervising the forthcoming edition of the British Pharmacopœia."

Dr. BANKS seconded the motion, which was carried by acclamation.

Dr. QUAIN said he was completely taken by surprise at the compliment paid him by the Council. Such a recognition was an abundant reward for any labours that he had [illegible] with the Pharmacopœia. He had only [illegible] his duty, and [illegible] was only too [illegible] of the work [illegible] credit of the Council and the [illegible]

The O[illegible] Committee [illegible] a report in reference to [illegible] hall of meeting [illegible] Dr. L[illegible] [illegible]

Embankment. The first is that which immediately adjoins the Temple Gardens, and lies between them and Sion College. The cost is four shillings per foot square. The second site is on the Savoy Estate of the Duchy of Lancaster; and any portion of this site suitable for the purposes of the Council could be had at about two shillings per foot square rent per annum. It was assumed that a space of ground seventy-five feet by fifty feet would give ample accommodation in a well-planned two-storey building for a dignified and suitable council-chamber and the necessary offices. The letting of the present premises would in all probability balance the new rent of £675 incurred for the site. The Committee had considered Dr. Lyons' report, and were of opinion that one of the sites on the Savoy Estate of the Duchy of Lancaster would alone be adapted to the purpose, provided the Council were satisfied as to the necessity of removal and the convenience of the proposed site, and were prepared to incur the increased expenditure involved in the change.

Dr. LYONS, in moving the reception of the report, said that in the opinion of an architect whom he had consulted for his own guidance, the difficulties in the way of properly adapting the present building to the purposes of the Council were almost insuperable. After a careful inquiry over an extensive area in London, the only available sites appeared to be the two mentioned in the report.

Dr. QUAIN (a member of the committee) urged that the proposed site in the Savoy was objectionable on the grounds of inconvenience and expense. The rent of the present premises was £300 a year, but they were worth £600; while that of the premises in the Savoy would be £700 or £800. He thought that the existing premises could easily be so modified as to suit the purposes of the Council.

Dr. STORRAR (also a member of the committee) expressed his concurrence in the views of Dr. Quain, and objected to the large expenditure that would be required to erect a new building on the proposed site.

Dr. A. SMITH said the first question to be decided was whether the Council was willing to invest its large capital in a new and costly building.

Mr. SIMON thought that the Council should resign itself for the present to existing circumstances, and not go into the indefinite experiment of either largely altering the present premises or going to another site.

Mr. TEALE also recommended the Council to remain in its present premises. He thought that another room less objectionable than the present could be erected in another part of the building.

Dr. WATSON moved as an amendment: "That the report of the Offices Committee be referred to the Executive Committee with instructions that they continue the inquiry in the direction of improving the present premises, with powers to take professional advice, and to report to the next meeting of the Council."

Mr. TEALE seconded the amendment, which was agreed to. On its being proposed as a substantive motion,

Dr. STORRAR moved as an amendment: "That the report of the committee be referred to the Executive Committee with power to take such steps, under professional advice, as they may judge desirable to further improve the ventilation of the hall in which the Council meets, or, if necessary, to report on the improvement of the building at the next meeting."

Dr. QUAIN seconded the amendment, which was agreed to; and it was also passed as a substantive motion.

Sir H. PITMAN proposed: "That a committee be appointed to consider and report in what way, if any, the accumulated funds of the General Medical Council can be applied in promoting scientific research for the public good." The first consideration, he said, was whether the Council had power to appropriate any of its funds to scientific research. He thought it would be found that the Council had such power. Certainly it had funds at its disposal. From the account published last year it would be seen that during the last three years the average surplus income over expenditure had been £2[illegible] a year, and during the last seven years the average had been £19[illegible]. The Council had now standing to its credit the sum of £[illegible]. That included sums in the hands of the Branch Councils; but, of course, the whole of these funds were under the direction of the General Council. The Branch Councils had no special interest apart from the General Council. They were permitted to have the control of a certain portion of the registration fees, but they were [illegible] to the General Council [illegible] entire supervision of the funds, as would be seen by a reference to the Medical Act. The Act declared that "all moneys received by any treasurers arising from fees to be paid on registration, from the sale of Registers, from penalties or otherwise, shall be applied for the expenses of registration, and of the execution of this Act." The only question was whether his proposal would come strictly within the meaning of the words, "the execution of this Act." That it was so, he thought, would be clear from Clause 54:—"The General Council shall cause to be published under their direction a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matter and things relating thereto as the General Council shall think fit, to be called the British Pharmacopœia; and the General Council shall cause to be altered, amended, and republished such Pharmacopœia as often as they shall deem necessary." His contention was that some portion of the Council's funds might be applied under that clause to investigations in relation to the British Pharmacopœia. To show the intention of the Legislature in such matters, he might refer to the Dentists Act, Clause 32, which said that all moneys received should be applied in accordance with such regulations as might be made by the Council in defraying the expenses of registration and other expenses of the execution of the Act, "and, subject thereto, towards the support of museums, libraries, or lectureships, or for public purposes connected with the profession of dentistry and dental surgery, or towards the promotion of learning and education in connexion with dentistry. In recent Medical Bills introduced into Parliament there had been a provision that any surplus funds might be applied to the promotion of such purposes as were contemplated for the profession of dentistry. Science had of late years made great advances, especially in connexion with sanitary questions, and the health of the public had greatly benefited by the improvements that had been carried out. He was anxious that some of the accumulated money of the Council should be expended in what, perhaps, might be called the physiology of therapeutics, with a view to making improvement in that direction, and keeping pace as far as possible with the progress of science in other directions connected with the profession. Why should the Council go on accumulating thousands of pounds every year? Notwithstanding the large expenditure on visitations, the Council had at least enough money at its disposal to justify it in applying some portion of its funds in the promotion of scientific research for the public good. The committee should, he thought, be a large one, so as to comprise every section of the profession.

Dr. Duncan, in seconding the motion, said it would be for the committee to inquire, amongst other things, whether the proposed expenditure was justified. For his own part, he thought it a very great grievance that the Council should possess such a large sum of money. If it could not get rid of it in the way proposed, it should do so in some other way. The responsibility of having so large an accumulated fund, making no use of it, and having no prospect of making use of it, was an unmixed evil.

On the motion of Mr. Simon, the debate was adjourned at the rising of the Council.

Friday, May 15th.

Sir H. Acland, President, in the Chair.

The debate on Sir H. Pitman's motion for a committee on scientific research was resumed.

Mr. Simon regarded it as absolutely unquestionable that the Council had nothing to do with the object named by Sir H. Pitman, and that any expenditure in the direction he had proposed would be a breach of trust. The Council was authorised to publish a Pharmacopœia; but that could not include the power to publish accounts of scientific researches such as those named by Sir H. Pitman. If the Council was receiving more money than it wanted, it could reduce the registration fee from five guineas to three, which would be quite within its power to do. He had had a good deal to do with grants for scientific research, and could assure the Council that the difficulties connected with the subject were very great.

Mr. Marshall said if it could be shown that all the expenses of the Council could be met by a registration fee of three guineas, the fee should be reduced to that sum. At present that could not be done, but in a few years he thought it could be easily carried out.

Dr. Struthers thought that the powers of the Council were very limited, and did not extend to expenditure for scientific research. The funds, however, could legally and usefully be applied to an extended system of visitation of examinations.

Dr. Watson hoped that the discussion would set at rest for ever the question of applying the funds of the Council to scientific research.

Dr. Humphry hoped that in future the visitation of examinations would be carried out more energetically than it had been. That was certainly an object to which the funds of the Council could be properly applied.

Dr. Lyons reminded the Council that it might have duties to perform which would require a considerable expenditure. He referred especially to the visitation of examinations, which ought to be widely extended and embrace every branch of education. It would be a great misfortune if such a work were hampered by pecuniary considerations. There ought to be a thorough annual inspection and report to the Council, and it was impossible to say what the consequent expenditure might be. For that reason he deprecated legislation in the direction proposed by Sir H. Pitman.

After some remarks from Dr. Smith,

Sir H. Pitman, in reply, said it was singular that the members who opposed his motion had not before discovered that the registration fee might be reduced. His proposal was not that money should be at once expended for scientific research, but only that a committee should be appointed to consider whether that course could be adopted. As to visitations, if any great improvement had taken place (as had been alleged) the necessity for them should be less rather than greater. The cost of a visitation was enormous; but the expense of researches such as he had mentioned would be comparatively small, and it would have, he contended, a distinct relation to the Pharmacopœia, and would therefore be strictly legal. It was a dereliction of duty on the part of the Council to be receiving large sums of money which it could not usefully employ.

Dr. Lyons moved as an amendment: "That a committee be appointed to consider and report in what way the accumulated funds of the General Medical Council can be best applied for the public good in conformity with the duties imposed upon the Council under the Medical Act."

Dr. Pettigrew seconded the amendment.

The President said he could not understand on what principle they were to conclude that if they had the power and the means they were not at liberty to inquire into the mode of action of those substances of which they were in the habit of prescribing doses. He also called attention to several previous meetings of the Council when similar proposals had been considered.

Dr. Storrar thought that if the proposed committee were appointed, it ought to have the power of consulting counsel on the legal aspect of the question. He sympathised with the object of the motion, but could not consent to an illegal expenditure of money.

The amendment was then put, and negatived. The original motion was also negatived by a considerable majority.

The following report was presented from the Finance Committee:—

The Finance Committee report that the income of the General and Branch Councils for the year 1884 (ending Dec. 31st, 1884) has been £8424 2*s.* 3*d.*, an amount which exceeds by £478 14*s.* 9*d.* the income for the year 1883. The expenditure during the year 1884 has been £7084 6*s.* 7*d.*, which is £2633 0*s.* 1*d.* more than the expenditure of 1883. The Committee has, nevertheless, the satisfaction of reporting to the Council that, notwithstanding the large expenditure during the past year, the excess of income over expenditure for the year 1884 amounts to £1339 15*s.* 8*d.* The excess of income over expenditure for the year 1883 was £3494 1*s.* As regards expenditure, the largest item of increase has been that for fees to members of the General Council, in consequence of the two sessions of the Council held during the year 1884. This excess amounted to £1580 1*s.* 10*d.* The fees to members of the Executive Committee also show an increase of £173 11*s.* 8*d.* The preparation of the new edition of the British Pharmacopœia has involved an expenditure on account of £358 12*s.* 2*d.*, and in general printing there has been an increase of £39 12*s.* 7*d.* The only items of diminished expenditure for the year 1884 claiming notice, as compared with 1883, are a decrease of £18 14*s.* 5*d.* in house expenses, and £13 14s. 6d. in the production of the Medical Register. While, therefore, the total increase of expenditure is £2310 7s. 1d., the total decrease amounts to £82 2s. 4d., showing an actual increase in expenditure of £2228 4s. 9d. The average yearly income during the last seven years exceeds the average yearly expenditure by £1617. In the receipts (£585 17s. 11d.) of the Dental Registration Fund for the year ending December 31st, 1884, there is a decrease of £82 6s. 5d. over those of last year, while the expenditure, £896 2s. 9d., has been greater by the sum of £151 4s. 7d. The deficiency of income for the year is thus £310 4s. 10d., as compared with a deficiency of £76 13s. 10d. in 1883. Pursuant to instructions given at the meeting of the English Branch Council in 1884, the treasurers have made an additional purchase of £2500 consols in the names of the trustees of the Branch Council, thus making a total invested under this trust of £23,000 consols. The total amount now invested by the three Branch Councils is £38,669 17s. With respect to the reference from the General Medical Council—namely, "To present a scheme which will render it necessary in future that the Branch Council for England should advance the money required to meet the current expenses of the General Medical Council,"—the Finance Committee recommend the following plan to be adopted in future:—1. That an estimate of the sum probably required for the current year's expenses of the General Medical Council having been made by the Executive Committee at their first meeting in each year, the proportionate rate to be paid by each Branch Council in order to provide such sum be made by that committee, and that the half of that sum be paid in January and July of each year. 2. That the sums paid by each Branch Council be placed to an account to be opened at the bank in the name of the General Medical Council. 3. That any balance remaining on this account at the close of each year, over and above what has been required for the expenses of the General Council for that year, be calculated in the estimate of the sum required for the following year; or should there be any deficiency, that the respective Branch Councils supply such deficiency computed on the percentage rate.

The report was received and adopted without discussion.

Mr. MARSHALL moved: "That it is desirable that the first principles of physics, chemistry, and biology should be regarded as branches of a preliminary scientific training and of an examination, to be taken before the commencement of purely professional study." He thought there could be no question as to the proposal he had submitted being within the powers of the Council under the Medical Act; indeed, he thought it absolutely necessary that the question should be taken up. A circular had been sent to a number of persons asking their opinion on the subject, and many answers had been received. A large majority were more or less favourable to the establishment of some sort of special preliminary scientific examination. Inquiries had been addressed to fifty-eight persons: nine had sent no reply; eight were decidedly adverse, chiefly on the grounds of additional expense of time, and of the inexpediency of encumbering the curriculum; eight were moderately adverse; thirty-four were more or less in favour of the proposal; twenty-three were absolutely in favour of some form of preliminary scientific education; three were in favour of such a preliminary examination as was expressed in the conjoint scheme of the Royal Colleges of Physicians and Surgeons; and seven were in favour of such an examination, but thought it could not be carried out at schools for general education. The evidence was strongly in favour of the proposal, and no apology therefore was needed for his introducing it. It would, if carried out, have the effect of relieving the professional curriculum. It might be objected that a heavier burden in time and money would be imposed upon the students, but he did not think that that was an objection that the Council had to consider. It was rather an objection to be made by the withdrawal of those who could not afford the necessary education. If the number of students had to fall off, it was better that they should do so early in their career than that they should go through a long period of medical education, and then be disappointed. It had been stated that the supply of medical men was inadequate to fill up the waste, but that was really not the case. Taking an average of nine years, the number of students annually registered had been 1842, and the number of practitioners registered in the same time was 1109, showing an antecedent waste of 733. That was a proof that a number of men entered into medical training who never passed into the Register. It might be asked, How was the waste supplied? The antecedent waste before registration was 733 a year. The working waste was 856, and deducting that number from 1109 (the number registered), there was a balance of 253, representing the number entered on the Register yearly in excess of the waste. The number of students registered in 1879 was 2009. It would take those students five years to get on the Register, so that they would appear in 1884. The number of practitioners then registered was 1388, so that the antecedent waste had been 621, and the balance, after deducting 615 who had died and retired, was 713. They therefore need not be alarmed as to the question of supply and demand. There were many poor-law medical officers breaking their hearts on a salary of £50 a year who might get £100 a year if the numbers in the profession were diminished. He doubted, however, whether the proposed plan would really increase the length of time during which a medical student would have to study. A sound preliminary training would enable the students to get through their professional curriculum more rapidly, and time would in that way be saved. Experience showed that those who had had that kind of training were more apt students in their subsequent career. He had been very much surprised, however, at an answer given by one gentleman who said that he had not found that those who had a preliminary scientific training were more apt in their professional studies. His (Mr. Marshall's) experience was just the reverse. But should the preliminary training be conducted at the schools? It would, he thought, be futile to expect from the schools a sufficient preliminary education in the fundamental sciences. The latest report from the examiners at the Cambridge local examinations gave them but little encouragement to expect a good scientific training in the general schools of the country. The work would probably be best done in the scientific division of the medical schools, and it should be done before the students were permitted to register. The subjects to be taught were the principles of mechanics, physics, chemistry, and biology. He meant by biology a general outline of the systems of plants and animals, especially the structure and functions of vegetable and animal tissues. His object was to raise the lower ranks of the profession; the higher ones would take care of themselves.

Mr. SIMON, in seconding the motion, said as the subjects of education increased the more incumbent it became to provide for methodical teaching, without which students would find the task before them an almost hopeless one. General scientific subjects should be dealt with before professional subjects; the latter would then be more quickly and easily acquired. That view was enforced in a report of the Committee on Professional Education in 1869, which he had himself drafted, and which was accepted by the Council without alteration. The time at present given to medical education, forty-five months, was generally admitted to be too short. It might be long enough for a student who had had a preliminary scientific training; but without such a training at least fifty months should be given. With such a regulation the schools would provide the necessary instruction, say, in May, so that the students might begin their medical course in October; but they would be at liberty to acquire their preliminary knowledge where and how they pleased.

Dr. PETTIGREW thought that chemistry was too important to be treated as a mere preliminary subject. "Biology" was a vague term; and the necessary amount of knowledge respecting it could hardly be obtained in the way proposed. He should not himself object to lengthening the period of medical education, but feared that it might interfere with the needful supply of practitioners. He thought that, at present, the subjects of the curriculum were too numerous, and that their number should be lessened in order that they might be more thoroughly learned.

Dr. BANKS said there were many men entering the profession who were quite unfit for it. There ought to be two different grades in the profession, and five years ought to be the minimum period of study.

Dr. HUMPHRY, in supporting the motion, said that there was a very general feeling expressed by the gentlemen who had answered the questions addressed to them, that a general scientific should precede a purely professional education. The great defect in education was in regard to the knowledge of principles, and if this defect could be supplied at an early period, the advantage would be enormous when the professional studies were undertaken. There were doubtless great difficulties in the way, but the appointment of a committee might lead to their removal. An expression on the part of the Council that the course proposed was "desirable" would be a useful preliminary step in dealing with the subject.

Dr. Storrar said that the principle of the motion was enunciated twenty years ago in a motion brought forward by himself. Something more should now be done, and he hoped that a distinct recommendation would be given to the examining bodies. The scientific instruction at most schools was quite inadequate, but there were notable exceptions. At Eton and Rugby, for example, science was well and practically taught. At Bedford there was a complete laboratory, and the scientific training was excellent. As a rule schoolmasters, knowing nothing of science themselves, did not care about its introduction, but if there was a demand for it, it would no doubt be well taught. With regard to biology, it was absurd to suppose that it could be taught from books alone, but there was no reason why it should not be taught practically in the schools. He hoped that no attempt would be made to exercise control over the qualifying bodies; the Council should be content with forwarding a recommendation on the subject.

Dr. Haughton thought that at least a year's preliminary scientific training should be required from the students.

Dr. Chambers said that the brains of boys at school were not sufficiently developed to receive chemical and biological instruction. The subjects were of a special character, and should be included in the later medical curriculum. He did not object to the addition, but it was made at the wrong end.

Mr. Teale thought the Council was mixing up general and professional education. The great object was that good training should be given at school, without reference to the particular subjects selected; and the more they tried to increase the subjects of early education the more likely they were to deteriorate it. The subjects referred to in the motion belonged to professional training, and should be so regarded. Dr. Michael Foster, in writing on the subject, had said: "I would not recommend a special preliminary scientific examination. In order to be adequate, it must be by special examiners, and the almost necessary consequence will be that it will become sooner or later too exacting." There was unfortunately a tendency to add to the curriculum before the question of time had been decided. Every examination added would, he thought, tend to deteriorate true medical study. He often heard complaints that men who had gone through their curriculum were not so well qualified to enter upon the profession as those who were turned out many years ago. The schools were being turned too much into cramming machinery, and any addition to the examinations would only increase the evil.

Dr. Scott Orr said that when examined by the Scotch University Commissioners he gave evidence almost identical with the views expressed by Mr. Marshall. It was not, of course, to be expected that the boys would get all the required information at the schools. Boys going straight from school to medical study often lost their first year; they did not know how to study, and had to be taught the preliminary lesson. It was scandalous that there should be so many rejections at the first examinations. By such an examination as Mr. Marshall proposed the unqualified students would be filtered out early, and the qualified ones would be better able to pursue their studies after their preliminary training.

Dr. Struthers said that examinations were not to be trusted without a regular education at a college or university. He suggested that the consideration of the subject should be deferred until the question of the curriculum had been settled.

Saturday, May 16th.

Sir H. Acland, President, in the Chair.

The adjourned debate on Mr. Marshall's motion was resumed.

Mr. Macnamara said that every member of the Council must sympathise with the earnest desire shown by Mr. Marshall that the important subjects mentioned in the motion should be thoroughly and carefully studied, but at the same time there might very well be a strong difference of opinion as to the mode in which that study should be carried on. The proposal seemed to be that those subjects should be taken previous to the commencement of professional study, and when once examined upon they were to be put on one side. No one who knew anything about the profession would under-estimate a knowledge of chemistry, and he could not approve of the suggestion that the examination in it should be passed before the student was registered; he would, however, be prepared to go the whole length with Mr. Marshall if it was to be subsequent to registration. Mr. Macnamara then gave a detailed account of the manner in which the several subjects were taught in the Royal College of Surgeons in Ireland, and expressed his regret that the Council had not taken up the recommendations first, dividing the whole course of study into sessions, and allocating to each its various subjects.

Dr. Watson was glad that Mr. Marshall had brought forward his motion before the discussion commenced on the arrangements for study and examination in future. The present curriculum was certainly over-weighted. Some students of more than average attainment might succeed in it within the forty-five months, but in most instances those who did so had had a preliminary education of a very different kind from that which was to be obtained at an ordinary school. Generally, their being able to pass within the allotted time was due to the fact that they had virtually entered upon what might be called the intermediate professional studies before they passed into the rank of medical students. Mr. Marshall's proposal to put certain things into the preliminary examination appeared a very valuable one, as it would tend in some way to relieve the curriculum. Chemistry was not slighted by being put into the preliminary, but the chemistry which Mr. Marshall alluded to was what must, under any circumstances, be acquired before further steps could be taken in that science. But the question arose, When and how could physics and biology be studied? In his opinion there was only one way in which that could be done—namely, in those schools where such subjects were really taught. If there was one thing that was bad for a medical student, it was that, even if he did not pass his examination, he should carry on his study in further subjects. It was of the very highest moment that anatomical studies should not be conducted at the same time with clinical studies, for if they were it would be difficult to avoid the risk of carrying septic germs into the anatomical ward. Chemistry and physics might easily be dealt with in the winter session, and zoology and botany in the summer session. From every point of view it appeared to him desirable that the resolution should be passed.

Dr. Scott Orr considered that more than one year's study would be necessary to enable the student to pass the examination proposed. If the curriculum was extended at all, it should be in the direction of professional study, and not of preliminary study. Mr. Marshall's proposal might be all very well for university students, but extra-mural students would find it extremely difficult to comply with this regulation. He could not see the propriety of relegating chemistry entirely to the preliminary course. It should be, as it had hitherto been, a part of the first professional examination.

Mr. Macnamara proposed as an amendment: "That it is desirable that the first principles of mechanics, physics, chemistry, anatomy, and biology should be regarded as branches of a preliminary scientific training, and of an examination to be taken at the end of the first year of professional study."

The motion was seconded by Dr. Pettigrew.

Mr. Marshall said there appeared to be a unanimous opinion that the schools could not be relied upon for a *bonâ fide* scientific preliminary examination. The object of school education was to educate the mind in the instruments to be used for the acquisition of knowledge. There was no objection to boys at school being allowed to indulge themselves in botany, zoology, and the natural sciences generally—indeed, they ought to be encouraged to do so; but he did not think that any examination which might issue out of a study of this kind should be seriously taken into account. No examination in such subjects at this early period could be considered adequate as an introduction to professional education. It was necessary that there should be interpolated a truly scientific training which should be preliminary to the study of the human body as it existed in life and disease, which was the ultimate object of medical science. The intermediate training to which he referred should include mechanics, physics, chemistry, and general biology. It had been said that chemistry was so important a subject that it could never be taught properly if it were separated; but he could not understand why it should not be taught even more effectually by itself than when the student was attending to his strictly medical studies. With regard to biology (a word to which he did not, like some members, object), the object should be to educate the student in the elementary principles connected with the structure and action of living things. The question was whether the course of scientific instruction should be introduced between the general education and the professional one. The main point was that it should be given before the student was allowed to be put on the Register. As to prolonging the curriculum, that was a question still hanging over them, and it would have to be dealt with hereafter. His own belief was that if the proposed plan were adopted, there would be as many students passing in the fourth year as there were now. The curriculum would have to be prolonged directly or indirectly. To prolong it directly was, he thought, objectionable. It would make some students lazy, and would not increase the chances of any.

Mr. SIMON said that all were agreed that before the commencement of professional study the reasonable competence of the students in the scientific subjects that had been mentioned ought to be ascertained. The question whether the term "professional," "preliminary," or "intermediate" should be applied to them was a trivial one in comparison with the essential question itself, which was that before anthropological specialities began the student should have some knowledge of mechanics, chemistry, physics, and biology. No doubt they would have to look forward to more time being required. How could it be otherwise? When some of them were young men the amount of scientific training required for men entering the medical profession was not more than was now required for the veterinary profession. He hoped that the Council would affirm the principle that before entering on medical studies the student should understand something of the attributes of the inorganic and organic world.

Dr. QUAIN thought that the treatment of disease had deteriorated. In consequence of the attempt to cram science down men's throats they had very little idea of good practice. It was absurd to suppose that the scientific knowledge now demanded could be acquired at school. The question was whether a five years' course should be required; and if so, how the time could be best spent.

The PRESIDENT said there could be no doubt that a scientific preliminary education, whatever it *might* be called, had become a necessity as an introduction to anthropological studies; and it was impossible that so much work could be put into the time at present prescribed.

Dr. LYONS was afraid that the medical student of the future would be in the position of Ginx's baby. He did not question the necessity of some such legislation as was indicated by Mr. Marshall's motion, but he was not sure that it would not be better to defer the consideration of the question until after they had taken up the question of the Council's recommendations. He thought that not less than two years' serious study would be required for a respectable knowledge of the first principles of physics, chemistry, and biology. Anything short of that would be practically useless. A two years' course would bring the student to the age of eighteen; and then nothing less than a four years' course would suffice for a thorough education in medicine, surgery, midwifery, pathology, anatomy, ophthalmology, and the other branches of which a full knowledge was required from the student before he was admitted to practise. That would bring him to twenty-two—the earliest age that should be allowed for admission. The two years' scientific preliminary training could be better given in one of the recognised universities, and it would, he thought (without committing himself definitely on the subject), be better to recommend the Legislature to establish a preliminary course in a university before admission to professional study. He hoped that the consideration of Mr. Marshall's motion would be deferred.

Dr. HAUGHTON thought that the Council was wandering from the real question, and discussing a great variety of details. The present regulations of the Council, to which the licensing bodies had assented, limited the period of medical study to four years, which included chemistry, physics, and biology; and they ought not to take the corporations and universities by surprise by passing Mr. Marshall's resolution without letting them know that it meant five years instead of four. If five years was the right time, let the Council say so. He for one would vote for it if the Council thought it right.

Dr. STRUTHERS said that a five years' course would be required if the preliminary scientific knowledge was not to be a mere sham. For himself he would far rather have medical students come to him well trained in classics and mathematics and knowing nothing about biology than have them come with a mere smattering of science. He should vote for the amendment.

The amendment was then put and rejected, 7 members voting for it and 10 against.

On the motion being put,

Dr. STRUTHERS moved as an amendment: "That the Council postpone its decision on the motion until it comes to decide on the questions of professional education and examination."

Dr. PETTIGREW seconded the amendment, which was put and rejected.

The original motion was then put, and on a show of hands there were nine in favour and nine against: but on the names being taken there appeared to be 9 in favour and 10 against, and it was accordingly declared to be lost. Three members did not vote.

Mr. SIMON moved: "*That the statements which have* been made to the Council, that the Council's accumulated funds amount to £38,000, and that the Council's annual income exceeds its annual expenditure by an average amount of £1600, be referred to the Finance Committee and to the Executive Committee; and that these Committees be instructed jointly to inquire, and jointly to report their opinion to the next meeting of the Council, whether the registration fee of £5 now charged to each person who enters the medical profession is more than enough to provide for the full efficiency of the Council in all its branches of duty, and whether the Council might properly proceed to make a reduction of the fee."

Mr. MARSHALL seconded the motion.

Dr. A. SMITH said that as three out of the four members of the Finance Committee were on the Executive Committee, he saw no reason why the matter should be referred to both committees.

Mr. SIMON said that Dr. Scott Orr, a valuable member of the Finance Committee, was not on the Executive Committee, and it was desirable to secure his services.

Dr. HAUGHTON had a strong objection to refer the matter to a committee; it was a question which the Council ought to decide itself. The benefit proposed to be given to the individual practitioner was infinitesimal, forty shillings once in his lifetime. It would be much better for the Council to keep its surplus so that it might be able to spend it on some useful objects.

Dr. STRUTHERS said that the money could be usefully spent on a more continuous visitation of examinations, and he proposed to move at a future sitting that the subject should be referred to the Branch Council to consider and report on it to the Council at its next meeting.

Dr. CHAMBERS considered that the money in the hands of the Council should be spent in such a way as to benefit those who had contributed it, and that to apply it to the reduction of future fees would be unjust to the old practitioners.

Dr. HAUGHTON moved as an amendment: "*That the* question of the reduction of fees on registration be now decided by the Council."

The motion having been seconded, was put and carried by 13 votes against 2.

Dr. HAUGHTON *then moved that the registration fee* remain *in statu quo*, and this, having been seconded by Dr. PETTIGREW, was also carried by a large majority.

Dr. CHAMBERS moved, "That the Council sanction the following decree passed by the Convocation of the University of Oxford, Feb. 24th, 1885:—'That no person shall be henceforward presented for the degree of Bachelor of Medicine who has *not* passed a qualifying examination, not only in medicine, but also in surgery and midwifery before the Examining Board for England, unless or until an examining board be appointed by the University for that purpose.' And that the Council also sanction the adoption by the Colleges of Physicians and Surgeons of England of the following resolution of the Committee of Management of the Examining Board for England of the said Colleges:—'That every member of an English university who shall have passed such an examination or examinations at his university as shall comprise the subjects of the first and second examinations of the Examining Board for England, and who shall have completed not less than four years of medical study according to the regulations required by his university, be eligible for admission to the third or final examination of the Board, two years after his having passed all the other required examinations.'" He said that by the 19th Section of the Medical Act any of the Colleges or bodies might, with the sanction and under the direction of the General Council, unite in conducting the examination required for qualifications to be registered under the Act; and he now applied for the sanction of the Council to a temporary arrangement made by the University of Oxford with the Conjoint Board of the Colleges of Physicians and Surgeons of England. The degree of B.M. conferred by the University was not a degree authorising the recipient to practise, but only to teach and lecture. The licence to practise was given separately. When the Act of 1858 was passed, the M.B. degree was made a qualification, and was admitted on the Register by the authority of the Council; the Council, therefore, was responsible for it. The University, in order to carry out loyally the direction of the Council, had gradually increased its standard of examination. Then came the recommendation from the Council that all persons who received a qualification should be examined in surgery and midwifery. The University thought that if it went on increasing its standard in medicine according to the improvements in education, it must also increase it in midwifery and surgery; but it was felt that that would be oppressive to the candidate. The difficulty might, it was believed, be overcome by the arrangement mentioned in the resolution.

Sir H. Pitman, interposing, said he thought that the Council had no authority to interfere in the matter, and that it was purely a question for the University of Oxford.

The President said that there was a legal question involved in the matter which had not yet been settled, and it was doubtful whether the Council had anything to do with it. Dr. Chambers, however, had acted quite rightly in bringing it before the Council, which he had done on his own responsibility.

The further consideration of the matter was adjourned.

Monday, May 18th.

Sir H. Acland, President, in the Chair.

On the adjourned debate on the motion for sanctioning the decree passed by the University of Oxford,

The President said his attention had been called to the fact that in the decree in question reference was made to the "Examining Board *for* England," there being no such body. It should be "the Examining Board *in* England."

Dr. Chambers, in resuming his address, said he had brought the matter forward as the representative of the Convocation of the University. The University had endeavoured to carry out the recommendations of the Council in regard to examinations in midwifery and surgery, and it was of opinion that such examination for Bachelors in Medicine would be best carried out in London. He asked for the sanction of the Council to the arrangement, without which the University might find itself in an awkward position, not knowing whether its examinations had been legalised or not. His attention had been drawn to the misdescription mentioned by the President. His belief was that the error was in the original decree; and in order that the error might be rectified, he would ask permission to withdraw his motion, on the understanding that he might be permitted to bring it forward again and discuss it on its merits.

Permission having been given,

Dr. Humphry gave notice that he should move that in order to prevent misunderstanding the representative of the University of Oxford be requested to make it known to the University that there is not, at the present time, any examining board for England.

The Council then went into Committee to consider the existing recommendations of the Council, and the proposed alterations, herein adopted by the Branch Councils for England, Scotland, and Ireland.

In Recommendation 19, "the age of twenty-one shall be the earliest age at which a candidate shall obtain a licence to practise, and the age shall in all instances be duly certified," no alteration was proposed by the English Branch Council.

Dr. Haldane, on behalf of the Scotch Branch Council, moved the substitution of the word "should" for "shall," urging that the former word was more appropriate to "recommendations," which had not the force of actual laws.

Dr. Haughton seconded the motion.

Mr. Simon thought that a distinction should be drawn between opinions of the Council that were imperative (such as those relating to the earliest age for admission) and the opinions that were merely the subjects of recommendation. The former, he thought, should take the form of standing orders.

Dr. Watson supported the motion, which was put and agreed to.

Dr. Banks moved "That the age of twenty-two be the earliest age at which a candidate shall obtain a licence to practise." If, he said, the question of age were considered after the question of the curriculum had been disposed of, he thought there would be a general consensus of opinion in favour of his motion. He was not alone in the opinion he had formed; for the King and Queen's College of Physicians, Ireland, had recommended that no candidate should be admitted to practise before attaining the age of twenty-two; and Sir Wm. Gull had recommended twenty-three as the earliest age. He (Dr. Banks) had brought the subject forward on a previous occasion, and at Mr. Simon's suggestion it was postponed until the subject of medical education was under discussion. They had had abundant evidence that the period of forty-five months, or even four years, was too short for an efficient education; and the result was that a number of immature youths had been admitted into the profession. If eighteen were the minimum age for admission to the Register, that would answer the purpose equally well.

Dr. A. Smith seconded the motion, which, on being put, was rejected by a large majority, there being only two votes in its favour.

Dr. Watson moved the omission of the word "duly" before "certified," regarding the word as meaningless. He said that the affidavit of the candidate himself as to his own age was accepted as a sufficient certificate.

The motion was seconded by Dr. Pettigrew and agreed to.

In Recommendation 20, "No licence shall be obtained at an earlier period than after the expiration of forty-five months subsequent to the registration of the candidate as a medical student,"

Dr. Haldane proposed to add the words, "and his commencement of study at a medical school." The object of the addition, he said, was to prevent candidates from being registered who had merely become pupils of a registered practitioner. The Scotch Branch Council was aware that in a number of cases students had availed themselves of that mode of commencing medical study, and in that way a year or more had in some cases been deducted from the period of education.

Dr. Fergus seconded the motion.

Mr. Macnamara said it was felt by the Irish Branch Council that the work with a registered practitioner was a sham. They accordingly proposed that the recommendation should read, "No licence shall be obtained at an earlier period than at the close of the attendance on four winter and four summer sessions of medical study subsequent to the registration of the candidate as a medical student."

Mr. Macnamara's speech was interrupted by the announcement of the President that the hour had arrived when, according to arrangement, the Council had to consider the case of a medical practitioner summoned to answer the charge of having caused to be registered in the Medical Register a qualification which he did not possess. This case (that of Ebenezer Bryceson) was considered in private, and occupied nearly the remainder of the sitting, being then postponed for further consideration on Thursday. It wanted only a few minutes to the hour of adjournment when strangers were readmitted, and it was then considered too late for Mr. Macnamara to resume his speech. The remaining time was accordingly spent in the transaction of some formal (chiefly dental) business.

Sir H. Pitman said it had been thought desirable to reconsider the standing orders with reference to penal measures, as to which there was at present no very clear mode of procedure. Such cases were becoming more frequent and more difficult to deal with, and it was desirable that the rules respecting them should be more exact. He moved: "That the Executive Committee, with the assistance of the legal advisers of the Council, be requested to revise

Sections 11, 12, and 14 of the standing orders having reference to penal measures, and to make at the next meeting of the Council such recommendations as they may think fit for amending the same."

Mr. SIMON seconded the motion, which was agreed to.

A communication was received from the Lord President of the Privy Council, enclosing a copy of a petition of Mr. E. Wooton, praying that his name might be entered in the Register as a dentist. The communication was ordered to be entered on the minutes.

Mr. MACNAMARA asked if the matter would be brought on for discussion.

Sir H. PITMAN said there was nothing to discuss. The petitioner, who had presumably been in practice before the passing of the Dentists Act, now asked to be registered, the time given by the Act having long since expired. That of course would be quite illegal.

A communication was received from the University of Pennsylvania (Department of Dentistry) asking for the recognition of its diplomas. After a short discussion as to the character of the course of study at the University (which Sir H. Pitman said had been decided by the Council to be below the required standard), the matter stood over, at the suggestion of Dr. Haughton, for further inquiry.

The Council then adjourned.

TUESDAY, MAY 19TH.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

The debate on Mr. Macnamara's motion on Recommendation 20 was resumed.

Mr. MACNAMARA said it was strongly believed by the Irish Branch Council that four years of professional study were essential. The subject was more important than all the other recommendations put together, and if they did not take a firm stand upon it, it would be a sad thing for professional education. What had the Council done to promote the study of the numerous essential subjects named in their recommendations? They had decided that it could all be included in twenty-four months' study in a school; but would anyone gravely maintain that an adequate education could be given in all those subjects in so limited a period? He had not forgotten that by another regulation a year and a half of study could be carried on under a general practitioner. One subject on which the Irish Branch Council felt strongly was the subject of unqualified assistants. Students who had not completed their curriculum, or had not obtained any qualification, were allowed to go to a general practitioner for a year and a half, and that time might be accepted as a portion of the four years. The student, unqualified as he was, might even visit the sick poor or people of higher rank. In Ireland no such thing could happen. He had served his time as a dispensary doctor for some years, and if he had attempted to send one of his apprentices to visit a poor patient he would have been summoned before the board and summarily dismissed. He maintained that four winter and four summer sessions were little enough in which to teach subjects of so important a character. If the resolution proposed by Mr. Marshall, that the preliminary scientific subjects should be taken before the commencement of purely professional study, had been carried, the Council might then have been in a position to state that three winter and two summer sessions would suffice. With a view to making the recommendation as definite as possible, he begged to ask permission to substitute for the original motion the following: "That Recommendation 21 should be as suggested by the Irish Branch Council, that the course of professional study required for a licence shall occupy at least four years, of which four winter and four summer sessions shall be passed in any school recognised by any of the licensing bodies in Schedule A of the Medical Act."

Mr. COLLINS, in seconding the motion, said there could be no doubt that twenty-four months of medical study were insufficient for a student entering the medical profession. As to the study under a medical practitioner, in the majority of cases it was of very little value. A large number of practitioners would be unwilling to give the necessary instruction, and a still larger number of students were unwilling to receive it. After a long course of general practice, he could himself say that he had only had one pupil who was willing to receive the instruction that he (Mr. Collins) was able and willing to communicate. He had offered to prepare them in the [illegible], but he could not get them to read; generally they preferred newspapers or novels.

Sir HENRY PITMAN said that Recommendation 21 required four years' professional study. The Irish Branch Council recommended that there should be four winter and four summer sessions. The question really was where the four years were to be passed. Hitherto it had been stated that at least three winter and two summer sessions should be passed at a medical school, leaving it to the discretion of the student to remain the whole time at the school or to spend some portion of the time with a registered practitioner.

Dr. HAUGHTON suggested that, as the Irish Branch Council accepted the Scotch proposal as far as it went, Mr. Macnamara should withdraw his motion in its favour, and bring forward the Irish proposal in connexion with Recommendation 21.

Mr. MACNAMARA assented to that course, and obtained permission to withdraw his motion.

Dr. HALDANE said that the Scotch proposal, which he moved, was: "No licence should be obtained at an earlier period than after the expiration of forty-five months subsequent to the registration of the candidate as a medical student, and his commencement of study at a medical school."

Dr. BANKS said he wished to move as an amendment (as suggested by the Royal College of Physicians, Edinburgh): "That the curriculum should extend over five years." There was, he said, a large body of opinion in favour of that proposal, and there was a very general feeling that the period of four years was not sufficient. It appeared from a return of the University College that only 23 per cent. of their candidates passed in four years. With one exception, the period of study required in England was shorter than that required in any other country. The period in Holland was seven years; in Sweden six or seven, and sometimes ten; in Denmark two years scientific and five medical; in Norway seven years; in Belgium seven years, sometimes six, and exceptionally five; in Russia five years; in Turkey six years; in Greece five years; in Italy there was no law, but the customary period was six years; in France six years for university study and examination. It was within his own experience that the period of four years was insufficient. Clever and industrious young men who passed the examination at the end of forty-five months were often so conscious of their unfitness to begin practice that they sought for a residentship in a hospital, or endeavoured to obtain instruction elsewhere, so as to be prepared to enter professional life. The recommendation of the Royal College of Physicians, Edinburgh, which had his hearty concurrence, would, he thought, commend itself to the Council. He knew what the arguments were against any prolongation. One gentleman had stated that the time at present required was as much as the student's social and pecuniary condition would allow. He (Dr. Banks) thought that they ought not to increase the facilities for entering the profession. It was, on the contrary, desirable to extend the period, and make the examination more stringent and expensive. His remarks, of course, did not apply to the universities. In the university which he represented the earliest age at which students entered was seventeen, and it was very improbable that less than five years could be passed in scientific and professional education.

Dr. HAUGHTON seconded the motion, adding that there was no chance of carrying it.

Dr. HALDANE said that, although he was personally in favour of a minimum of five years, he could not vote for it since he was, as the mover of the motion, the mouth-piece of the Scotch Branch Council, which had not adopted the proposal.

Mr. SIMON said that the question was virtually the same as that which the Council had refused to settle on Saturday. When Dr. Banks spoke of five years he no doubt intended that the studies of physics, chemistry, &c., should be included in that period. If so, a great deal might be said in favour of the motion. But if it was the intention that the whole period of forty-five months should be spent at a medical school, however desirable it might be for the student, he thought it would be retrograde legislation. If it could be safely said that there was no part of the medical curriculum that the student could acquire elsewhere than at a medical school, by all means let there be an absolute rule that the whole period should be spent at a medical school. But if it might be assumed that certain parts could be learned elsewhere, they had no right to make a rule of that description. In fact, it would be a tyranny. His view of

Dr. Banks' amendment depended upon what arrangement was made as to the preliminary scientific subjects. His own opinion was that those subjects should be passed before the commencement of purely medical study. The best course, he thought, would be to have a few words at the end of the existing regulations to the effect that no licence should be obtained at an earlier period than after the expiration of forty-five months subsequent to the registration of the student, and subsequent to his having passed an examination in the first principles of chemistry, physics, and biology. If those subjects were cleared out of the way, the period of forty-five months would be equal to Dr. Banks' five years.

Dr. HAUGHTON said that Mr. Simon was endeavouring to revive a corpse. The question had been decided on Saturday. He himself agreed that a five years' curriculum was the best mode of accomplishing the object.

Dr. BANKS said he was willing to modify his amendment by requiring that the first year should be devoted to pre-professional training. Personally he should prefer six years to five, but perhaps that would not be tolerated.

After some further conversation as to the wording of Dr. Banks's amendment, it was submitted as follows: "That the course of study for registration, if including elementary mechanics, physics, chemistry, and biology, should occupy at least five years."

Dr. DUNCAN said that the amendment could not be adopted because the Council had already arranged a curriculum and an examination that were inconsistent with it. The preliminary examination was fully laid down in print, and would come into operation on October 1st.

Dr. QUAIN suggested that the new arrangement should come into operation two years hence.

Mr. SIMON said that the question as to when the regulations should take effect was a matter for subsequent consideration.

Dr. HUMPHRY said he supposed that forty-five months would still be considered sufficient if the candidate possessed an adequate knowledge of elementary mechanics, physics, &c., previous to registration.

Dr. QUAIN thought it would be better to fix the period and decide afterwards as to the subjects of study and how they were to be taken. The Council had decided twenty years ago that no licence should be obtained at an earlier period than after the expiration of forty-eight months subsequent to registration; and also that the examination in physics, botany, and natural history might be undergone at an earlier period than the first professional examination.

Dr. HAUGHTON: They had not discovered "biology" then.

The PRESIDENT said it was true that the Council had considered the matter twenty years ago, but now, after a long experience, it was thought desirable to reconsider it in the light of that experience, with a view of making any alteration that might be deemed necessary.

Dr. BANKS said that in former times, when there was not so many subjects in the curriculum, a five years' course was required.

The discussion was adjourned, and the remainder of the sitting was occupied by the consideration (in private) of the case of Daniel Sutherland, who had been summoned to appear before the Council.

The following extract from the printed Minutes shows the business transacted during the absence of the representatives of the press:—

Moved by Dr. HERON WATSON, and seconded by the Rev. Dr. HAUGHTON: "That the Council proceed to consider the case of Daniel Sutherland, who has been summoned to appear before the Council, and to deal with it in accordance with Clause 29 of the Medical Act."

Amendment, moved by Dr. LYONS: "That the further consideration of Daniel Sutherland's case be adjourned for the space of one calendar month, in order to give him time to prepare such defence as he may be advised to do against the serious charges now laid against him; and that Mr. Farrer be instructed to communicate this notice to him without delay."

On the motion of Dr. LYONS, seconded by Sir HENRY PITMAN, the debate was adjourned until the next day.

Strangers having been readmitted, the Standing Orders were, on the motion of Sir HENRY PITMAN, suspended until the completion of the business before the Council.

Moved by Dr. HUMPHRY, seconded by Mr. MARSHALL, and agreed to: "That with reference to the motion by Dr. Chambers, respecting a decree passed by the Convocation of the University of Oxford, Feb. 24th, 1885, in order to prevent misunderstanding, the representative of the University of Oxford be requested to make it known to the University that there is not, at the present time, any Examining Board for England."

Moved by Sir HENRY PITMAN, seconded by Dr. SCOTT ORR, and agreed to: "That the following communication from the Faculty of Physicians and Surgeons of Glasgow be received and entered on the Minutes:—

'April 25th, 1885.

'SIR,—I am directed to transmit to you a copy of the subjoined resolution of this Faculty, passed at the ordinary meeting held on 2nd March, ult., and confirmed at the ordinary meeting held on the 6th inst.

'I am, Sir, your obedient servant,
'ALEXANDER DUNCAN, Secretary.

'W. J. C. MILLER, Esq., B.A.,
'Registrar of the General Medical Council.'

"Moved by Dr. Yellowlees, seconded by Professor Gairdner, and unanimously agreed to: 'That in the opinion of this Faculty instruction in insanity should be made compulsory in medical education; and that an expression of this opinion be transmitted to the General Medical Council.'"

(It will be observed that the Minutes state that after the case of Sutherland was adjourned strangers were readmitted. No intimation, however, was given to the representatives of the press who were in attendance that the Council was in open session, and hence no report was taken of the subsequent proceedings on Dr. Humphry's motion respecting the decree of the Convocation of the University of Oxford.)

WEDNESDAY, MAY 20TH.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

The PRESIDENT said he desired to make a personal explanation. He wished to express his regret that on the occasion of the motion of Dr. Humphry on the previous day he had not taken the opportunity of drawing the attention of the Council to the matter. He had no idea that Dr. Humphry was in earnest in bringing the motion forward. It would be remembered that the Council had been in very serious and difficult discussion on legal business. They were on the point of breaking up, and the members were in movement, when Dr. Humphry proposed his motion, which was, in fact, a vote of censure on the University of Oxford. In the peculiar position in which he (the President) stood towards the University, it was manifest that he should say nothing in its defence or explanation concerning it, and he should therefore call on the representative of the University to make any observation that he might desire to offer. But, in fact, he did not take the matter *au sérieux*, and he allowed it to pass, the motion being carried without any observation. He would not go into the merits of the case, except to say that the University of Oxford had for many years done its utmost to develop education in the direction it thought fit, with express regard to the action of the Medical Council and to the interests of the country. Its desire was not to fly in the face of the general endeavours of the Legislature to establish combined examinations, and not to fly in the face of the general sentiment of the country by multiplying qualifying titles and diplomas. Acting in good faith, it had decided that it would in its educational arrangements accept the examination of a certain body composed of eminent persons in the metropolis; upon which, without any discussion or observation, a message was ordered to be sent to the University, having reference to a decree which it had passed in a loyal spirit, that there was not at the present time any "Examining Board for England." He was sorry that Dr. Humphry was not now present. What was the meaning of the communication to the University he could not, as president, state. All that he could say was that the motion had been moved by Dr. Humphry, seconded by Mr. Marshall, and passed without observation. It would have been well if the representative of the University had ascertained precisely what the University had done. He had not seen Dr. Chambers, but he had himself telegraphed to Oxford to ascertain the exact words of the decree in question, and he had been informed that the words were "the Examining Board *of* England.' That was not right, for the words should be "*in* England." As a matter of fact, however, the University had not used the words mentioned in Dr. Humphry's motion. If there was anyone to blame it was himself for not being quick enough, in the confusion just before the Council adjourned, to call attention to the matter. He could not suppose that so curt a rebuke upon somebody unknown was to be made, and so the thing passed. He was sorry that he had not been quick enough to call Dr. Humphry's attention to the subject, and ask him to defer it until further information had been received.

Dr. HAUGHTON said it would be remembered that the transaction occurred within a few minutes of the hour of adjournment, at a time when the Council did things that it would not think of doing at any other period of its sitting. There ought now to be an appeal from Philip drunk to Philip sober. He presumed that Dr. Chambers, when moving for the Council's sanction to the decree, was referring to the conjoint scheme of the Colleges of Physicians and Surgeons.

Mr. SIMON hoped that the President would confer with Dr. Chambers and Dr. Humphry, with a view of bringing about a satisfactory arrangement. The motion was not irregularly passed, although it was quickly disposed of, the chairman of the Business Committee moving the suspension of the standing orders for the purpose. He hoped that the President would allow the matter to drop for the present.

Mr. MACNAMARA said that the suspension of the standing orders was moved *sotto voce*, and in such a hubbub that the proposal did not reach him; otherwise he should have objected to it.

Dr. CHAMBERS said that he had made a mistake in the description of the Examining Board. He believed its full title was "The Examining Board in England of the Royal College of Physicians, London, and of the Royal College of Surgeons of England."

Mr. MARSHALL said that as he had seconded Dr. Humphry's motion, some explanation might be expected from him in Dr. Humphry's absence. The object of the motion was merely to correct an error that had been made, and not to propose a vote of censure. It did not appear to him that the matter was very serious; but if it was so regarded by the President, he would give notice of motion that the Council should leave it to the discretion of the representative of Oxford to make the communication in any way he liked.

Dr. DUNCAN said there was no such body as "The Examining Board in England."

Sir H. PITMAN: It is "*an* Examining Board in England."

Dr. DUNCAN: Everybody knows what is meant; it is the Conjoint Board of the two Colleges.

The PRESIDENT: We must ask the representative of the University to communicate to them the full title of the Board. Of course, if Dr. Humphry's motion had been simply a request to the representative to point out that the expression used in the decree was not an accurate description of the Board, and that it should have been so-and-so, there would have been no objection. But this curt message is such as to startle anybody.

Dr. QUAIN: All that Dr. Humphry meant to do was to correct an inaccuracy.

The matter then dropped.

Sir HENRY PITMAN: When the Council rose yesterday I felt it my duty as Chairman of the Business Committee to look back and see what we had done during the last eight days, and also to look forward and see what we had to do during the few days that remain of this week. I am sure no one would desire that we should sit into next week. On looking at the programme I do not suppose anyone is sanguine enough to imagine that we can get through the business before us this week. We have forty-five distinct questions on these reports by the Branch Councils alone, and there are other questions besides. To-morrow will be in part occupied by a legal case, and then there will only remain Friday and Saturday; and I feel persuaded that if this business is got through it will be done in so hasty and unsatisfactory a manner that it will bring some discredit upon the Council. Therefore I venture to suggest that, after what fell from our solicitor yesterday as to what ought to be the notice given to Daniel Sutherland for his appearance here, we should not commit even the appearance of an act of injustice, but give him fair notice and time for his defence

Dr. WATSON reminded Sir Henry Pitman that the reporters were present.

Sir HENRY PITMAN: Then I will abstain from any further remarks upon the legal question; but in regard to the time at our disposal I think after conference with the President, who agrees with me, that it would be far better to have a short session before the year expires, and that all such legal cases should be submitted to that session. We shall then get on as far as we can with the business programme of to-day, and anything which may be left unfinished, and I am satisfied that there will be much left unfinished, might also be taken at the next meeting. I think it my duty to state these facts to the Council.

Mr. SIMON said he could not quite share the pessimist views of Sir Henry Pitman. There appeared to be one or two really difficult questions in connexion with the recommendations, one of which was almost decided on the previous day, and when that question was decided the remaining business, he thought, was not more than might be got through during the present week. It would be much more convenient to get the business through during the present week than to have an indefinite future appointment.

The PRESIDENT then read a letter which he had received from Sir Henry Pitman embodying the substance of his verbal communication to the Council as to the time occupied by legal business, and asking permission to take the opinion of the law advisers of the Crown as to the readiest mode of carrying into effect the penal clauses of the Medical Act.

The Council then proceeded to consider in private the case of Daniel Sutherland, who had been summoned to appear before it under Clause 29 of the Medical Act.

On the readmission of strangers, the Registrar announced that, having heard evidence and considered the defence of Daniel Sutherland as stated in his letter of May 13th, the Council resolved and adjudged him, after due inquiry, to have been guilty of infamous conduct in a professional respect, and, further, directed his name to be erased from the Register.

The adjourned debate on the reports by the Branch Councils in regard to the recommendations was resumed.

Dr. BANKS submitted his amendment to Dr. Haldane's motion in the following form: "That the course of medical study after registration should occupy at least five years, if the subjects of elementary physics, chemistry, and biology are included in that period, or at least four years if a satisfactory examination in these subjects has been passed previous to registration."

Dr. STRUTHERS, in supporting Dr. Haldane's motion, said he was strongly of opinion that four years of genuine study were sufficient, and that a fifth year would be a tax on ability and industry, keeping back the better-class of students. An average man, if industrious, could complete his course satisfactorily in four years. Many of the physicians and surgeons who had sent in their answers to questions addressed to them had declared their opinion that a period of four years was ample. Some said that four years were not enough. Not enough for what? Of course not enough to make consulting physicians or surgeons; but that was very different from simply entering on the practice of the profession. In Germany the period was four years, and during the whole of the first year the student was working at chemistry, zoology, mineralogy, and natural philosophy, the first examination taking place at the end of the second year. The French system was also an example in favour of Dr. Duncan's proposal.

Dr. DUNCAN said there was not much difference in the two proposals, but Dr. Banks' amendment overturned the decision of the Council as to the preliminary subjects, and he should therefore vote against it.

Dr. PETTIGREW supported the motion, and said he thought it would be very foolish to keep back industrious and intelligent youths and encourage lazy ones by extending the period to five years. He hoped that the Council would see its way to adopt that recommendation, and would be careful to introduce only such subjects as were fundamental and necessary. The students ought to have fewer subjects and more time to reflect as they proceeded with their education.

Dr. WATSON said he objected to Dr. Banks' amendment because it did not compel the student before beginning his professional study to put behind his back the subject of systematic chemistry, neither did the arrangement compel the students to pass an examination in systematic chemistry at the end of the first session, but he would be permitted to carry it on to a period in the course of his curriculum in which the study of it would seriously interfere with the study of such matters as anatomy and physiology. If a period of forty-five months were properly made use of it ought to afford abundant time for the student to acquire the kind of formal systematic knowledge which was all that could be really expected from him.

Mr. Simon, in supporting the amendment, said he could not see in the Scotch motion any security for getting in the purely medical education the desired relief from the preliminary subjects. If the professional curriculum was to be weighted with the elementary subjects five years would be wanted to do justice to it. The amendment permitted an alternative of four years with the understanding that an intermediate examination was passed before the strictly professional studies commenced.

Dr. Banks referred to the case of Austria, where a period of five, six, and sometimes seven years was required, and cited Billroth's figures to that effect. Almost every young physician in England found it necessary to prolong his studies beyond the four years before commencing practice. The Scotch bodies were not unanimous in regard to their recommendation of four years, the Royal College of Physicians, Edinburgh, recommending five. At the Royal College of Surgeons, England, only 23 per cent. of the candidates obtained their diploma in four years.

Mr. Marshall recommended that the matter should be delayed, with a view of obtaining more unanimity on the subject. He was willing to accept the alternative provided in Dr. Banks' amendment, for there ought to be a certain flexibility in the arrangement, and it ought not to be too strictly enforced on the corporate bodies. Hospital authorities would not allow a house-surgeon to be appointed unless he was qualified, and if a man were not allowed to qualify until he had had an additional year of study a hardship would be inflicted on the student.

Dr. Humphry thought the Council should be careful not to extend the minimum period of education too much. The question was whether the period assigned was sufficient to enable a student to obtain a fair knowledge. Fifteen per cent. now passed into the profession in the assigned period, and they ought not to be prevented from earning their livelihood. He did not suppose that any of the licensing bodies would at once alter their arrangements.

Mr. Teale considered it important not to choke up the minimum examination to be passed in four years. In the Leeds Infirmary there were four persons under the house-surgeon who used to be called assistant resident medical officers. Until recently they were students who had passed all the requisite examinations, but had not obtained any qualification. Four or five of the best students were always competent for such appointments; but a year and half ago it was decided to appoint only qualified men, and the result had been that only on one or two occasions since had students from the infirmary school competed. He was inclined to vote for the modified, elastic proposal by Dr. Banks; it would still be open to the licensing bodies not to adopt it at once if they did not see good reason for it.

The amendment was carried by 11 to 8, and was also agreed to as a substantive motion.

The following foot-note was agreed to without discussion:

"*Exception may be allowed in the case of* any graduate in Medicine of an Indian, Colonial, or Foreign University, or of any student who, having completed the full time required by the Medical Council, and having given satisfactory evidence of general education, shall have spent the whole or three-fourths of that period at an Indian, Colonial, or Foreign University, the several licensing bodies being requested to communicate to the Council annually, in the month of January, a statement of the action taken by them respectively during the last preceding *calendar year in regard to such exceptional cases.*"

The following existing Recommendation was then considered:—"The course of professional study required for a licence should occupy at least four years, of which four winter and three summer sessions should be passed at any school recognised by any of the licensing bodies mentioned in Schedule A of the Medical Act."

Sir H. Pitman moved: "That the Recommendation be as follows:—'At least three winter and two summer sessions shall be passed at some school or schools recognised by one or more of the licensing bodies.'"

Mr. Simon seconded the motion.

Dr. Haldane moved as an ammendment: "That the recommendation be as follows:—'At least four winter and three summer sessions should be passed at any school recognised by any of the licensing bodies mentioned in Schedule A of the Medical Act.'"

Mr. Macnamara seconded the motion. He maintained that the subjects were so extensive, and the examinations so searching, and in some respects so practical, as well as theoretical, that the time mentioned in the amendment was the least that should be required if the student was to be adequately instructed.

The debate was then adjourned, and the remainder of the sitting was occupied with the transaction of some formal dental business.

Thursday, May 21st.

The debate on Recommendation 21, respecting the time to be passed by the student at a recognised school, was resumed. Before it concluded, the Council proceeded (in private) to the further consideration of the case of Ebenezer Bryceson, which occupied nearly all the remainder of the sitting. On the readmission of the public, it was announced that the Council had decided that Ebenezer Bryceson had been guilty of infamous conduct in a professional respect, but did not, under all the circumstances, now direct his name to be erased from the Register. The Council then adjourned. It was stated that the sittings would not be prolonged beyond Saturday.

THE
PRELIMINARY SCIENTIFIC M.B. EXAMINATION.

The revised regulations for the above examination at the University of London have just been issued. The examination will take place twice a year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates only commencing on the third Monday in January. Candidates for the Pass Examination will be allowed to take all the three subjects of the examination—(*a*) inorganic chemistry, (*b*) experimental physics, and (*c*) general biology—at the same examination, or to take them at two separate examinations—that is to say, two subjects at the First Examination for which they may enter, and one subject at the Second Examination; or, reversely, one subject at the First Examination, and two at the Second. At the July Examination candidates have the option of entering for a Pass or Honours in inorganic chemistry and experimental physics; but they cannot take up Honours in botany and zoology unless they have entered for the whole examination, including—that is, a Pass in general biology. In chemistry and physics no candidate will be allowed to take both the Pass and the Honours papers in the same subject; but if he enter for Honours and fail to obtain them, he may be recommended for a Pass in those subjects provided he has shown a competent knowledge. The examiners will make no report upon the examination for Honours of a candidate who has failed in any part of his Pass Examination.

A detailed syllabus of the subjects required in a Pass Examination is given, and also of the subjects required in the Zoology Honours Examination. The following are the requirements for a Pass in general biology:—

The elements of vertebrate morphology and physiology as exemplified by the rabbit, the fowl, the pigeon, and the frog. The description of the external form and the nomenclature of the parts of these animals. The leading resemblances and differences in the plans of structure of the three. The chief features in their osteology, with especial reference to the skull and limbs, and the visceral anatomy of each, including the general structure of the brain, the spinal cord, and the sense organs. The histological character of blood, epidermal and epithelial organs, connective tissues, cartilage, bone, muscle, and nerve in these animals. The characters and mode of formation of their ova and spermatozoa. The chief stages of the development of the frog, fowl, and rabbit. The nature of the placenta in the latter. The structure and life history of astacus, lumbricus, helix, distoma, hydra, vorticella, and amœba. The elementary morphology and physiology of the flowering plant. The description of its external form. The leading modifications in the structural plan of the flower. The leading types of fruits; the modifications by which floral organs take part in their structure. The histological characters of the growing point both in stem and root; the mode of origin and leading characters of epidermal, fibro-vascular, and ground tissues. The development of foliar organs and of the branches of stem and root. The mode of origin, structure, and ultimate development of ovules and of pollen grains. The mode of development of the embryo and of the endosperm. The distinctive facts in the life history of pinus. The structure and life history of a fern, a moss, chara, fucus, penicillium, spirogyra, mucor, protococcus, saccharomyces, bacterium. Practical examination (six hours). Each candidate must be prepared to examine microscopically, to dissect, and to describe, specimens of the animals and plants referred to in the preceeding syllabus.

There is also a practical examination in chemistry, comprising qualitative analysis of the more commonly occurring bases and inorganic acids, in solutions containing one of each. A list of reagents and apparatus provided for this examination is appended.

The regulations, although issued too late to appear in the current volume of the University Calendar, will come into force at once; or rather candidates, who so desire, will be allowed forthwith to take advantage of the changes introduced in the revised regulations.

THE LANCET.

LONDON: SATURDAY, MAY 23, 1885.

DURING the past fortnight the agitation for increasing the facilities for obtaining degrees by students educated in the London medical schools has been steadily progressing. On one point all are agreed—namely, that industrious students of average ability and sound professional attainments are placed at a great disadvantage if they elect to pursue their full curriculum in the metropolis. In spite of what we may perhaps venture to call the best professorial and teaching staff and the greatest clinical opportunities that can be found anywhere, students are debarred from entering the London medical schools, and are driven elsewhere by the want of facilities in obtaining degrees. At the present time a degree is not only the object of legitimate ambition of a well-informed student, but, owing to the multiplication of universities and the easy terms on which it can be obtained in most university centres except the metropolis, it has a distinct commercial value to the practitioner, and this is being recognised more clearly year by year. The question, then, of how a similar advantage can be fairly secured to the London as to the provincial student is most pressing, and one which London teachers and educational authorities are anxiously considering and endeavouring to answer. In a multitude of counsellors there may be safety, but just now chaos reigns supreme, and all kinds of solution of the difficulty are being proposed and eagerly pushed into prominent notice. The practical methods of solving the problem are very few, and may readily be pointed out. The University of London is naturally the first institution to which we must turn. But the prejudices in favour of the vested interests of the present holders of its medical degrees and the traditions of the University will, in spite of all appeal, oppose any such levelling as is contemplated in the idea of a degree for average students. We have always contended that the University of London has mistaken its true function, and has sacrificed its real position as the centre of metropolitan medical education and the *alma mater* of London students, to the lesser aim of maintaining a high examination-standard, and of only numbering a select few among its graduates. Indeed it was only after a long struggle, and in the most grudging spirit, that the slightest departure from its ancient *rigid* regulations has been conceded. The Vice-Chancellor, at the recent presentation for degrees, intimated that little else than some slight modifications in its *entrance* examination would be done by the Senate to meet the popular demand. The degrees of this University, according to Sir JAMES PAGET, must only be obtained by showing a greater amount of medical knowledge than is required by any other degree-granting body. The prestige of its degrees must be steadily maintained. That this isolated position is not held by all the members of the Senate and graduates is well known, and is clearly shown by the action of Lord Justice FRY'S Committee of Convocation; but much pressure, and a steady infusion of educational reformers into the ranks of the Senate will be required before they are likely to be induced to depart from this standpoint; and the life tenure of its senatorships, aided by Crown nominations, is a grievous difficulty in the way of any real reform. All we can expect is petty tinkering and some small modification of the existing regulations. Seeing this, those who are anxious that all impediments should be removed from a medical student's career in London have turned their attention to the great corporations of the Royal Colleges of Physicians and Surgeons, and the recent fusion of their examinations has made the moment a most favourable one. On his recent re-election as president, Sir WILLIAM JENNER suggested that this question of degree-granting should be inquired into by the two Colleges; and last week the Council of the College of Surgeons, by a unanimous vote, appointed seven of its most influential members as delegates to meet a similar number from the College of Physicians, and confer as to "what steps, if any, can be taken to enable the two Colleges to obtain the legal right of giving the title of 'Doctor' to persons who shall have obtained the licence of the Royal College of Physicians of London and the diploma of the Royal College of Surgeons of England." This movement has apparently caused great surprise, and, now that it has an actual existence, a great conflict of opinions as to its wisdom. The proposal is to give the *title* of "Doctor," and not to confer *degrees* such as M.B., M.D., M.S., or B.S. The scheme will probably have the sympathy of most London teachers, and the best wishes for its success among the London students. On the other hand, it will be sturdily opposed by the graduates and authorities of every university in the kingdom, who will look upon it as an infringement of their rights and privileges. "Degrees should only be given by universities" will be their contention, and the conferring of a title will be confused by them with the granting of a degree. A greater objection, in our opinion, is that, although the medical examinations of the two Colleges fully warrant such a title, those in Arts and Science cannot be deemed satisfactory. A second division in the second class of the Pupils' Examination at the College of Preceptors, even if a Latin author who is never changed and a modern language be taken up, is too low a standard, and some other preliminary examinations now deemed sufficient for registration are but little better. A title of "Doctor" should imply more than this minimum of education in Arts. Physics and Chemistry are included in the Conjoint Examination Scheme, but Biology is unrepresented, and surely some slight acquaintance with this science should be a necessary preliminary to a title of "Doctor." These defects in medical education seem to us greater objections to the present movement than the opposition which may be anticipated from the Universities, in many of which medical examinations are less searching and complete than at the two Colleges.

Another body which must also be referred to in this question is the embryo Teaching University for London, whose future it is as yet very difficult to forecast. Will it merge into the University of London? If so, it will probably be of small use to students of medicine, however much it may affect those in Arts and Science. But if it attains to an independent existence, and holds out its hands to the great legal and medical corporations, as well as to the educational bodies, it may be of the utmost service to medical education by supervising the preliminary knowledge and examining in Arts and Sciences, leaving the strictly technical examinations to the existing authorities. We infer that some such idea exists among its promoters, as at its meeting on Monday last, in considering how boards of studies and a governing body should be best constituted, so far as the Faculty of Medicine is concerned, it was expressly stated that in addition to the teaching element, representatives of the Royal Colleges of Physicians and Surgeons would be invited to take seats amongst the governing body.

◆

The General Medical Council has displayed a new quality. Its most redoubtable champions, up to Saturday last, would not have maintained that, with all its virtues, it was capable of promptitude. But in one brief moment the supposition of this "fair defect of nature" has been refuted. One act of decision gives hope of more, and we can only trust that a new future of firmness and business-like faculty is in store for this much-abused body. The peculiar nature of the subject in regard to which the Council showed this unexpected quality may be thought by some to derogate from the significance and the merit of its action. There is certainly something in the proximity of money which taints even the best natures, and throws a certain air of vulgarity over the highest conduct. So it is rather unfortunate that the noble action of Saturday had reference to a financial question. The Council is in trouble about money matters; not in the vulgar way of impecuniosity,

> "That horrid *want* of pence
> That vexes public men."

The difficulties of the Council are all the other way—the *embarras de richesses*. But, even so, they are becoming serious. Last year the Council received, chiefly from the shallow pockets of the entrants of the profession, no less than £8424 2*s*. 3*d*.—the largest sum, we presume, it has ever received in one year. Certainly there is nothing like it in the last seven years; and it is in excess by £478 14*s*. 9*d*. of the sum received in the year 1883. There is one virtue that nobody will deny the Council—that of knowing how to spend money; and with rising income it feels the corresponding duty of expenditure and cultivates its powers. Still it did not succeed in the last twelve months in making ends meet. It succeeded in spending the handsome sum of £7084 6*s*. 7*d*.—more by £2633 than the expenditure of 1883, and this upon perfectly impalpable objects, —but yet had to leave £1339 15*s*. 8*d*. unexpended, to be added to the ever-increasing investments of the Council, which now amount to £38,669 17*s*. The average income of the last three years has been £7884 12*s*. 6*d*., and the average expenditure £5452 1*s*.—showing an annual excess of income of £2432 11*s*. 6*d*. This is the pleasant dilemma of the Council—an income altogether disproportionate to the work done, and the prospect of an ever-increasing disproportion. The best members of the Council feel a good deal of discomfort on the subject, and a corresponding desire to do something to abate the scandal. Accordingly, two or three schemes have been suggested for this end. One, by Sir Henry Pitman, proposed the appointment of a committee to consider in what way to use the accumulated funds of the Council, so as to promote "scientific research for the public good." Dr. Lyons moved an amendment to this, and required that the application of the funds, while for the public good, should be "in conformity with the duties imposed on the Council under the Medical Act." Both these motions were negatived without much discussion on Friday, the 15th inst. But it was on Saturday, the 16th, that the unprecedented display of promptitude and decision occurred on a proposal by Mr. Simon, seconded by Mr. Marshall. The motion was altogether reasonable and to the effect that the Finance and Executive Committees should consider and jointly report to the next meeting of Council whether the registration fee of £5 is more than enough to provide for the full efficiency of the Council, and whether the Council might properly proceed to a reduction of the fee. The very thought of delay in dealing with such a motion was intolerable. It was demanded that the Council itself should decide the great question immediately and on the spot. And, accordingly, all forms of notice being dispensed with, the Council went straight to the affirmation of the following proposal by Dr. Haughton:—"That the registration fee remain *in statu quo*;" and then, with an easy mind, broke up for the Sunday's rest. The profession, however, will not contemplate the growing proportions of this disused and ever-increasing fund with the same satisfaction unless work is done by the Medical Council very different from what it has done this session, or even in the two sessions of last year, when it succeeded in spending £7084, and nearly £3000 of this over its own members. We cannot point to one act of the Council in the present session or in the last year that is of the least consequence in regard to medical education, or to one discussion that would redeem the reputation of the Council as a public body charged with vindicating the sanctity of medical registration and the rights of registered practitioners.

As a specimen of the work over which the £7000 is spent, we will give one instance, not to revert again at present to the perennial theme of Preliminary Education. The Council has been understood of late to be full of great ideas of extending the time of medical education, and throwing back the age at which a licence to practise could be secured. The existing Regulation as regards age is as follows:— "The age of twenty-one *shall* be the earliest age at which a candidate shall obtain a licence to practice, and the age shall in all instances be *duly* certified." Two great operations have been performed on this recommendation. The word *should* has been substituted for *shall*, and the word "duly" has been omitted altogether. Even with such discussions the Council cannot use up its large income, and yet strenuously opposes any diminution of it. Will Parliament and the profession always be so powerless to control a Council at once so useless and so costly?

The Council, on Wednesday last, passed a motion by Dr. Banks, seconded by Dr. Haughton, extending the course of study over five years, if the subjects of elementary physics, chemistry, and biology are included in that period; or at least four years, if a satisfactory examination in these subjects has been passed previous to registration. This recommendation looks serious, but Dr. Matthews Duncan declares it to be practically a mere reaffirmation of the existing recommendation of the Council, which contemplates the disposal of the subjects of physics and chemistry before the commencement of the four years of strictly medical study. And so the money of the profession and the time of the Council are spent.

◆

THE Report of the Royal Commission on the Housing of the Working Classes has been received with a very general feeling of disappointment. The constitution of the Commission, and the time and labour devoted to the collection of evidence, had created hopes which have not been realised. It had indeed been expected that some definite and substantial remedy would be advanced for conditions which have long been thoroughly recognised and universally condemned. That the Report is almost barren in this respect is, perhaps, due less to an inability on the part of the Commissioners to grasp the subject with which they have had to deal than to difficulties which surround the question on every side.

If further evidence were required, it has been abundantly forthcoming, that overcrowding and its attendant evils exist to a very large extent in the metropolis and in other large towns, and that this, moreover, is the result of circumstances which the State has not been well able to control. Working people, with small and variable earnings, have been obliged to live near their employment, and hence opportunity has been given for high rents to be demanded for the worst accommodation; middlemen and others interested in house property have bought up the ends of leases when houses have been falling into decay, and have failed to keep them in proper condition. Freeholders have, in their turn, neglected to exercise the powers they possessed for maintaining their property in habitable condition, and sanitary authorities have not exerted themselves to enforce the provisions of the Sanitary Acts which affect this question. Thus, by neglect of duty with regard to the state of repair of dwelling-houses and by a system of overcharge, the working classes have suffered heavily both in their pockets and in their comfort.

But even if freeholders and sanitary authorities had done their duty and the owners of tenement houses had been satisfied with moderate profits, there would still be a great lack of accommodation, for at the present time the scarcity of space upon which suitable dwellings can be erected presents a physical difficulty which is not easily met. Increased facilities for railway travelling at reduced fares may assist a few to live at a distance from their work, but the loss of time spent in daily journeys is in itself a severe tax to those for whom time has a money value.

Thus, the Report has had to concern itself with a multitude of considerations, each, perhaps, important in its way and having more or less bearing upon the subject; but it leaves a strong impression that the remedies suggested are not very potent, while some of them raise questions of considerable moment. For instance, the proposal to devote for the purposes of artisans' dwellings the forty-five acres in the metropolis now occupied by prisons is an expedient that would give temporary and partial relief to the congestion of the districts in which the prisons are situated, while the further suggestion that in fixing the price "due regard should be had for the purposes to which it is intended to devote the land" has, indeed, raised a question which appears in its true light only when consideration is given to Lord SALISBURY's proposal that the sites should be sold at cost price to some trust that will build workmen's dwellings upon them. The greater the desire to find an effectual remedy the greater the risk of accepting a principle which, on the face of it, seems to commit the State to socialism; for in this sense only can be construed the suggestion to provide accommodation for less than its money value. It is, however, a well-recognised fact that the condition of the working classes reacts on the whole community, and no objection need be taken therefore to the recommendation that the State should lend money for the erection of artisans' dwellings at the lowest possible rate, without loss to the national exchequer.

The enunciation of the principle upon which we have dwelt is, so far as we can see, the one thing novel in the Report; for the rest, old-fashioned remedies are once more exhibited. The amendments which are recommended in existing Acts appear to be well considered, and probably some good would result if they were carried into effect; thus, the proposal that the cost of proceedings under TORRENS' Act should in small districts be shared by adjoining districts will perhaps give some impetus to improvements under this statute. Again, the proposal to revive Lord SHAFTESBURY's Act, which under the vestries has been a dead letter, by transferring it to the Metropolitan Board of Works, awakes a hope that it may yet have some influence for good. Much stress has been laid upon the default of local authorities to make and enforce regulations under the 35th section of the Sanitary Act for houses let in lodgings. While fully endorsing the opinion that these regulations would be beneficial, especially for the reason that they would tend to shorten proceedings which are otherwise necessarily tedious, it is obvious that there has been too much disposition to judge of the work of local authorities by this criterion and to overlook the action they have taken under other sections. The recommendation with regard to the position of medical officer of health is important, as giving recognition to the value of the service rendered by this official; but it should not be forgotten that he cannot be debarred from practice until his remuneration is placed upon a better footing, and until his tenure of office is more secure.

But while Acts are amended and recommendations are made that their provisions shall be enforced, the motive power is still wanting for this purpose. Until a wider public interest is created in the metropolis and elsewhere in local affairs, alterations of the statute-book are of little avail. That the efforts of the Commission may assist in this direction is certainly probable. The fact stated by Lord SHAFTESBURY, that very great improvement had taken place in the last thirty years in the dwellings of the working classes, is itself full of promise; and we may therefore hope that this improvement will continue, although no immediate remedy has been indicated by which the change is to be brought about.

◆

THE report, which appears in another column, of a general meeting of the Association of Fellows of the Royal College of Surgeons of England, held on Wednesday last, contains the welcome information that a possible basis has been discovered for the combined action of the Associations of Fellows and Members in their endeavours to amend the constitution of the Council, and to reform the general and academic administration of the College. Many circumstances have co-operated to give to the Royal College of Surgeons of England a large and almost predominating influence over medical education in this country; but, we repeat, the College as a political body has hitherto consisted only of the four-and-twenty gentlemen who have succeeded in getting themselves elected members of the Council. Though by implication the College is made up of Fellows and Members and a small governing body named the Council, the latter, in accordance with the pernicious traditions upon which the College was originally founded, has arrogated to itself all the power, influence, authority, and prestige which should strictly belong to the whole of the body politic and corporate. For the first forty-three years of its existence the Council was not only self-elected (so-called), but every member of it was elected for life. Forty-two years ago the order of Fellows was constituted, from and by whom members of Council have since been elected for a period of eight years, though eligible for re-election. Experience has, however, proved that this alteration, for well-known reasons, has had but little effect in restraining the vagaries of the Council or in increasing the influence of the Fellows in legislative acts of the College. After election every member of the Council at once passes out of the reach of remonstrance by the Fellows. How completely the Council regards itself beyond and above the censure of the Fellows is shown by its repeated rejection of many of the recommendations proposed by the Association of Fellows to be introduced into the new Charter. But, grievous as may be the lot of the Fellows, that of the Members is worse. From the first day of its existence until now the Council has done all within its power to render the status of *Member* of the College contemptible. Every charter, bye-law, standing rule, and ordinance has been conceived and executed in a spirit of antagonism to the Members. Members have been denied the right to sit in, or vote for members of, the Council, and one of the first bye-laws made by the Council was to the effect that no Member of the College should be eligible for the office of secretary. The spirit of this bye-law is still zealously fostered. How significant is the contrast with the College of Physicians in this respect! When these and the other disabilities imposed on the Members of the College are borne in mind, it is not surprising that the Association of Members has been provoked to demand a due and authoritative recognition of the corporate and academic rights and status of Members. The first proposals of the Association of Members were startling in their extent and pretensions. To confer electoral privileges upon any and every medical student as soon as he should succeed in obtaining the diploma of Member would, we believe, be neither conducive to the welfare of the College nor useful to medical education and legislation. The compromise suggested by the Association of Fellows ensures a reasonable and equitable representation of the special interests of the Members, at the same time that it commits the care of these interests to the consideration and keeping of those Members whose stability and stake in professional life imply adequate obligation and responsibility.

Annotations.

"Ne quid nimis."

MR. ERICHSEN, F.R.S.

All who take an interest in the Royal College of Surgeons of England will learn with regret that Mr. Erichsen has resolved not to seek re-election into the Council next July. Few persons beyond those who have followed the business of the Council closely are aware of the great services which Mr. Erichsen has rendered to the Fellows and Members, and of the impetus which his efforts have given to the cause of reform. Immediately after his election in 1869 he redeemed his pledge to seek for the Fellows and Members the right of holding meetings in the College. To these endeavours they are indebted for the facilities for holding the two general meetings in the year 1870, and the memorable meeting of March last year, when the alterations proposed by the Council to be made in the Charters were presented. But not only were the Fellows and Members indebted to Mr. Erichsen for the facilities for holding the last meeting, but it was through his personal action and interference that the occasion was discovered and secured; otherwise the alterations would have been smuggled through the Council without their knowledge. At all times Mr. Erichsen has been a loyal and strenuous supporter of the rights of the Fellows and Members, and in return he may rest assured that he has won the confidence, respect, and esteem of all, to a degree and in a sense unusual to members of the Council, if not entirely unprecedented.

WORRYING THE "MAD DOCTORS."

It is characteristic of the human mind that when it once becomes disturbed on any subject it takes the worst possible view of the question at issue, and is liable at any moment to be worked, or likely to work itself, up to a very furor of indignation on the mere suspicion of personal wrongs in connexion with the suspicion awakened. This peculiarity is wont to assert itself, in and out of season, with striking, and occasionally inconvenient, force upon the slightest provocation. If a dynamite raid is made on public offices, private, and even obscure, citizens are panic-stricken with the fear of being singled out for the attack of the traitorous. If somebody suffers from lead-poisoning, the whole community is agitated with apprehension of a similar calamity. The diphtheria in milk of a small dairy supply in a limited area incites the multitude to eschew that generally wholesome and nutritive commodity altogether. There is therefore nothing unnatural, or indeed very remarkable, in the fact that those who feel themselves aggrieved by being, at any period of their lives, confined in lunatic asylums should take advantage of the opportunity afforded by a paroxysm of public lunacy law reform to worry the "mad doctors." Those who keep licensed houses for the insane, and those who sign certificates of lunacy, are having what our neighbours across the Atlantic euphemistically describe as "a bad time." We are sympathetically sorry for our brethren in trouble, and for those in bondage through fear of harassings and avengings similar to those which have fallen on the heads of the guileless, but, as it seems, not guiltless, victims of recent raids at law. How, and when will it end, this persecution of the innocent but wrong-doing medical practitioner in lunacy? Everybody who knew anything about the matter must have been aware that there was plenty of loose and perfunctory examining and certifying; and those who had adequate notions of the way in which the Commissioners in Lunacy had contrived to reduce their supervision to a ridiculous farce must have been prepared to discover that the existence of a standing Commission in Lunacy, so far as the safety of the sane was concerned, afforded no real protection. We are unwilling to aggravate the troubles of these troublous times in lunacy, or we could not hesitate to insist strongly on the need of entire reconstruction at Whitehall. Indeed, we sincerely trust that, as Lord Shaftesbury feels compelled to resign, advantage will be taken of the opportunity to place the Commission on a new and totally different footing, with some sort of guarantee that its duties will be discharged in the future better than they have been in the past. Something more than "ticking off" the inmates of asylums on a list, and looking to see whether pots are clean and sheets carefully folded, with a little office business consisting mainly of the mere clerk's work of seeing whether the blank places in certificates are properly filled in, is necessary for the welfare of the insane and the security of Her Majesty's rational subjects; and more may certainly be expected of a Commission which costs the country upwards of £15,000 a year. Except for the *publicity* involved in the presentation of reports to Parliament, we do not believe the Commission would be worth 15,000 pence. If the Commissioners in Lunacy had done their work earnestly in the spirit as well as the letter of the law, this worrying of the "mad doctors" would have been impossible, because there would have been nothing of which to make an occasion for persecution—nothing, in fact, of which to complain.

CONFERENCES ON CHOLERA.

The recent conference upon cholera held at Berlin did not make any notable advance upon the position taken up by the same body of scientists at their gathering last summer. To be sure, much has happened since then and a great deal more information has been obtained concerning the comma bacillus and its allies. Thus Professor Koch had in the first place to meet the numerous objections that have been raised during the past six months to his view that the comma bacillus is to be regarded as the actual cholera germ. The members of the conference now, as then, appear to have tacitly or openly coincided with Professor Koch's doctrine and all that flows from it. Indeed, had it not been for the presence of Professor von Pettenkofer there would have been little to debate about. Roughly speaking, the supporters of the bacillary doctrine represent the contagionist side, the opponents the non-contagionists, which has such ardent advocates as Dr. Cuningham and Sir Guyer Hunter. No doubt the battle will be fought over again at Rome, for Professor Koch represents Germany at the conference now assembled there. Professor von Pettenkofer's difficulties in admitting the comma bacillus to be the cause of cholera rested on many grounds, but in the main upon the epidemiological data, especially those having reference to the influence of locality and season. Yet he seems to have admitted the dissemination of cholera by human intercourse, although he could not admit that the introduction of a case of cholera on board ship could be the starting point of an epidemic. Altogether the doctrines enunciated by Professors Koch and Virchow seem to have had more cogency and to have been more definite than those advanced by Professor Pettenkofer. A great deal has been made of the question of drinking water, the purity of which does not seem to Professor Pettenkofer to be of such importance as the conditions of soil; and the often-cited instance of Fort William was claimed as proof of the truth of both assertions. But, as Professor Virchow pointed out, an improved water-supply necessitates improved means for the disposal of waste; and although the analogy he drew between typhoid fever and cholera may not be fully grounded, there is much to be said for it. The practical outcome of the conference was the recommendation of measures for the prevention of the spread of epidemics, the most important of which is the separation and isolation of the sick. At the same time the futility of the adoption of quarantine on land, such as, for example, was witnessed on the Italian frontier last year, was fully recognised. How far the conference at Rome will adopt the same course as that at Berlin is doubtful; in the present state of marked divergence of opinion and in view of the resolute tenacity with which unproved dogmas are held one cannot expect anything like unanimity from a heterogeneous gathering. Nor until agreement is arrived at as to the nature of the disease can we hope to formulate clearly the measures wherewith it must be combated with any hope of complete success.

THE ROYAL VISIT TO NETLEY.

Among the many noble qualities which characterise Her Majesty the Queen there is probably none which more endears her to the public than her sympathy with the afflicted and suffering. This has been often displayed in the case of her wounded soldiers on their return to their native land, and has not been wanting on the occasion of the present war in the Soudan. On Saturday last Her Majesty, attended by Princess Beatrice and Prince Henry of Battenberg, visited the sick and wounded in our great invaliding hospital at Netley. Her Majesty was met at the railway station by the General commanding the district and the Assistant Adjutant-General, and was attended by them to the hospital. There Her Majesty was received by Surgeon-General Murray, the principal medical officer, and by Professors Longmore, Smith, and De Chaumont, the chaplain, the Rev. J. C. Edghill, and Mrs. Deeble, the lady superintendent of nurses, who wore the Royal Red Cross and a medal conferred on her for her services in Egypt. Her Majesty visited the medical division, where the convalescents were drawn up in the corridor, the surgical division, where the wounded are under treatment, entering into conversation with many of them, and the sick officers' quarters. There were in the hospital at the time 71 wounded and 146 sick from the Soudan and Egypt, and shortly after Her Majesty left 83 more sick and wounded arrived from the Soudan. The effect of these visits of the Queen to the sick and wounded cannot but be gratifying to the army and cheering to the poor fellows, as showing the warm interest taken in them by Her Majesty and the members of the Royal Family. The visit on the present occasion was all the more to be appreciated as it involved a considerable amount of exertion and personal fatigue on the part of the Queen, who travelled from Windsor for the express purpose, returning to the Castle the same day.

CUTANEOUS AND DEEP REFLEXES.

The tenth original article of the *American Journal of the Medical Sciences* gives the results of some observations on the cutaneous and deep reflexes. Dr. Philip C. Knapp of Boston, U.S.A., has examined the condition of the reflexes in 239 individuals admitted to the Boston City Hospital during the latter half of the year 1883. The points noted were the presence or absence of the different reflexes in each patient, together with a comparison of the reflexes on the two sides of the body, and a rough estimate of the degree of contraction after irritation. The following are the conclusions at which the author has arrived:—1. Absence of the plantar or cremasteric reflex is usually pathological, depending upon a direct lesion of the reflex arc or some cerebral disturbance. 2. Absence of the other cutaneous reflexes is not necessarily pathological. 3. Absence of the patellar reflex may be due to cerebral disturbance, especially in alcoholic subjects. 4. Ankle and patellar clonus are pathological. 5. The deep reflexes of the upper extremity are of frequent occurrence, and have no special pathological significance. 6. The costal reflex is found in the majority of cases without general exaggeration of the reflexes, and with no signs of phthisis. 7. When the reflexes differ on the two sides of the body, though it usually signifies some unilateral disease of the nervous system, it is not always pathological. On the whole, the above propositions accord with the observations of Buzzard, Gowers, and others who have worked most at this important question. That the patellar reflex may be absent from cerebral disturbance is most probably correct; nevertheless it would be difficult in many cases to exclude the possibility of a direct damage to the reflex arc itself. The frequency with which the deep reflexes of the upper limb are present in cases of disease of the brain and spinal cord has probably been overlooked as the result of imperfect examination; and we are disposed to agree with the conclusions of Dr. Knapp.

BULLYING AT SCHOOL.

The parents of most public school boys have had to undergo the painful experience of obliging a poor little boy to return to school in a state of dejection, if not in abject misery. The child has gone willingly enough to his preparatory school, where his companions are very much of his own age, and where he can hold his own. There, also, he has been tended with some approach to parental care. But his first few terms at a public school, whether as day boy or boarder, are a new experience to him of trial and often of wretchedness. All this becomes more or less known to his parents in the holidays. When term time approaches the boy gets miserable. The family doctor is often called in to arbitrate between father and mother, and settle whether the poor little fellow is well enough to go back to school or not. It is not often that the same ordeal has to be undergone in the case of girls, for school to them has attractions and often fascinations which in most instances are absent from boys' schools. It is not that school mistresses are less severe in discipline than masters, nor that the work at a girls' is less arduous than at a boys' school. The difference is that little girls are much petted by the bigger girls, whereas little boys are commonly browbeaten and oppressed by bigger boys. Any boy brought up in a refined home, under the guardianship of sensitive and high-minded parents, will in all probability experience some of the heaviest trials of his life during his first year or so at a public school. He will be buffeted about by his bigger schoolfellows, and often subjected to coarse and obscene language, and there will be little or no redress for him. We do not imply that every elder boy at school is obscene and brutal; but in most schools there is a number of really bad boys, and these sometimes from the highest social rank. As one black sheep taints the flock, so one evilly disposed boy contaminates "the set" he is in, and bullies all weaker than himself. It is often opposed to the immediate interest of the school to get rid of such a boy, for his parents may be influential. There are few places where one law for the rich and distinguished and another for the poor and obscure are so tacitly acquiesced in alike by masters and governors as at our public schools. We have often been struck by the dread parents have of making their dissatisfaction known either to the authorities or through the public press, for fear of the unpopularity into which it may bring their boys. The terrorism big boys exercise over little ones is scarcely greater than that which schoolmasters exercise over parents, by reason of a fear of the consequences to the boys concerned. Sir William Harcourt is rendering a great service to English school boys by giving the prominence he does to the fatal case of bullying at King's College, and thereby causing an act of justice to be done to parents of every grade. We do not imply that King's College is worse than other schools; but there, and elsewhere, has existed a lack of discipline in the intervals of class. The decision arrived at by the governors of King's College, that for the future safety of the boys the masters are to keep watch in rotation in the intervals of class, implies that their system has been defective in this particular. Indeed, it virtually admits the existence of the bullying complained of in their school, or of something equally objectionable. On the particular case in question which Sir William Harcourt has directed shall be inquired into by the Public Prosecutor, it would not be fitting to express an opinion. If this sad death convinces school authorities that boys cannot be let loose from class, in the absence of adequate supervision, without risk of injury to each other, and danger to the reputation of their school, and, if an injury should prove fatal, that they cannot hope to escape henceforth, any more than King's College has, one of the gravest charges that can be brought against a public body or an individual—the inquiry instituted by the Home Secretary will not be in vain. Whenever death takes place at a public school, either from injury or from disease, the law should provide a public inquiry. In the past there has been too much hushing up of such things; hence the prominence we have given in our columns to all matters concerning the welfare of the English school boy. Now that the Secretary of State has taken up his cause, he may hope for a happier future.

THE PRELIMINARY SCIENTIFIC M.B. EXAMINATION.

The revised regulations for the Preliminary Scientific Examination, which will be found elsewhere, will, we fear, cause some disappointment. The concession that has been made by the Senate to the thrice-repeated demand of Convocation for a half-yearly examination is deprived of some of its grace by the withholding from the candidate who appears in January the chance of obtaining *distinction*. The Senate, in following what can only be supposed to be the recommendation of the examiners in this matter, has created a precedent for which there is little, if any, justification. To be logical, it ought forthwith to remove the Honours list from the January matriculation, for in what other respects does this Preliminary Scientific Examination differ in regard to medical degrees? Doubtless the intention is to encourage at least one year's study to intending candidates in Honours, and to make that year conterminous with the academical sessions. But as a matter of fact, there will be few youths so well prepared in the subjects of the Pass Examination as to present themselves for the Preliminary Scientific Examination within *at least twelve months* of passing matriculation, unless they avail themselves of the option given them to take up one or two subjects at a time. We are glad to see that Convocation has referred to its Annual Committee the question whether candidates who fail in one subject should be allowed to come up for examination in that subject only on a subsequent occasion. This would be most applicable to such an examination as the Preliminary Scientific, in which each of the three subjects of the Pass Examination is made to cover so wide an area. It must be confessed that the requirements of the examination have been placed very high. The subject of general biology, for example, includes a range of study that by itself would require prolonged and patient work, comprising a knowledge of animal and vegetable anatomy and histology, which there is at present little opportunity of obtaining. In the face of the extended requirements of the University of London, it is time that a serious effort be made to form science faculties and schools, which should have the sole responsibility of training youths in these preliminary subjects, and that no *medical* instruction be allowed to commence until this scientific study be accomplished. For all that, we are far from thinking that it would not have been both politic and fair if the University of London had taken the opportunity to demand a little less science from those who wish to graduate in its medical faculty.

DISINFECTION AND DISINFECTANTS.

A COMMITTEE of the American Public Health Association have issued a preliminary report on the subject of Disinfection and Disinfectants, and the views expressed on the subject are eminently sound. It is explained at the onset that disinfection necessitates the actual destruction of any specific infectious material which gives rise to infectious diseases, and that the destruction must not be partial, but complete, if true disinfection is to be obtained. Popularly, the term disinfection is used in a much broader sense, and mere deodorisers and antiseptics are styled disinfectants, the result being much misapprehension and failure; for many such agents are entirely without value for the destruction of disease germs. This applies, for example, to the valuable antiseptic sulphate of iron or copperas. Antiseptics, however, exercise a restraining influence upon the development of disease germs, and hence they have a proper place amongst the agents to be used for certain purposes when epidemic diseases are prevalent. Many so-called disinfectants now in the market are mere deodorisers, and are quite valueless for their professed purpose. Chloride of lime is held by the Association to be entitled to the first place for disinfecting excreta; it is both trustworthy and rapid in its action. A solution of corrosive sublimate and permanganate of potash in soft water, in the proportion of two drachms of each salt to the gallon, is placed next, as being really effective, but slower in its action. Liquor sodæ chlorinatæ is also referred to, but it is dearer than chloride of lime, and has no special advantages over it. For clothing and bedding which cannot be washed, a temperature of 230° F. is recommended as sufficient for the destruction of all known disease germs which do not form spores. Super-heated steam under pressure is, however, a safer method to rely on, and, as stated in the memorandum, a less temperature of this agent probably suffices to effect the object than is the case with a dry heat. The report contains useful hints as to the quantities of the agents to be used, and as to the methods of their employment.

THE PREVENTION OF BLINDNESS.

A DEPUTATION from the Ophthalmological Society of the United Kingdom, consisting of Sir Wm. Bowman, Mr. Jonathan Hutchinson, Mr. John Tweedy, Drs. M'Keown, Brailey, and Abercrombie, was received last week by Mr. Russell, M.P., Parliamentary Secretary to the Local Government Board, and by the Registrar-General; Dr. Buchanan was also present. It will be remembered that an interchange of views has for some time past been going on between the Ophthalmological Society and the Local Government Board as to the best means of making the public aware of the danger attendant upon inflammation of the eyes in infancy. Some months ago, as an answer to some propositions made by the Ophthalmological Society to the Local Government Board, the Registrar-General argued that the increased expenditure necessary for carrying out the proposals of the Society would prove an effectual barrier. At the deputation it was urged that the public should be instructed through the medium of the Poor-law organisation and the registrars of births, and it was pointed out how this could be done by the employment of printed forms, which should be given, along with the papers for vaccination, to the individuals registering births. Though we should have been better pleased with a more forcible mode of bringing home the facts to the minds of parents, yet it must be admitted that the plan above suggested will
probably be attended with much future benefi
munity if it be adopted, as seems not unlikely
Government Board. The benefit to be deriv
measures in preventive medicine may be ex
crease as years go by, for with the circulati
forms drawing attention to the perils o
neonatorum there must go on an ever-widenii
tion of knowledge.

THE THAMES SEWAGE COMMIS

IT will be remembered that the Metropo
Discharge Commission, appointed to inquire
condition of the tidal portion of the Thames,
report into two parts, separated from one anot
siderable interval of time. In the first part th
an overwhelming mass of evidence the existen
dangerous, and increasing nuisance, by which
fouled throughout almost the whole of the tidal p
second part, published after a second inquiry,
possible remedies. The Commissioners receiv
ance in the second part of their labours thar
because the Corporation of London backed
work they had commenced so vigorously.
to be generally admitted that the whole of
sewage must be carried down at any rate t
and that even then it must be purified before pa
river. Sir Joseph Bazalgette's scheme for takii
to Canvey Island, near Southend, seems to p
as, or better than, any other. The minute
taken in the second stage of the inquiry are n
and contain much valuable scientific matter a
maps and plans. Many well-known inventors
of sewage schemes were examined, among
mentioned Mr. Melliss, Mr. Sillar, and Mr. B
and their evidence will assist many in the
task of deciding among the competing schem
selves, we incline to the opinion that the m
system is precipitation followed by irrigatic
present frantic efforts of the Metropolitan Bo
to remedy the mischief they have caused, the
described as absurd.

MEDICAL EDUCATION IN BOM

WHEN the Grant Medical College was open
in 1845 the number of students was ten. Af
tuations it was as low as fifteen in 1864-65,
rose again to forty-four or forty-five in
average for the first twenty-eight years,
period the students had not to pay anythi
education, was about twenty-five. Since that t
the number of students has steadily and rapi
until it has reached three hundred, includin
class. The work of the hospital has also i
addition has since been made to that building,
College. Further, there has not been any appre
in the staff of teachers or in the hospital sta
under each professor or teacher therefore a
necessarily be, so large and unwieldy that it m
sible for the students to receive the benefit of
as well as when the classes were small. This
cannot be got rid of by merely enlarging the p
premises. The teaching staff requires to be
with the accommodation, and it has been sugg
best and the most effectual way to give the
relief is not to have duplicate classes and te
and the same college or building, but to have a
or medical school built in connexion with an
The proposal seems a good one, and it is to
the Government will give it a careful and d
sideration. The Grant Medical College with it

hospitals and the European General Hospital could still be conducted on the old system. But with this yearly increasing number of students, one medical college with one hospital for clinical and other teaching is not enough, and more than one such institution may well be considered absolutely necessary.

PROFESSOR OGSTON'S VISIT TO THE SOUDAN.

LAST week Dr. Ogston, the Professor of Surgery in the University of Aberdeen, who has just returned from the Soudan, where he went with a view "to increase his efficiency in teaching and to increase his own personal information," delivered a lecture to the students on some points of interest in connexion with his short stay at Sawakin. After a brief notice of the very inadequate provision made for the wounded on the field of battle in former wars, he gave an account of the organisation and working of the bearer companies under the present system, of the mode of transport to the field hospital, and of the arrangements there made for the prompt and efficient treatment of the cases as they were brought in. We have but one objection to this description as applied to the war in the Soudan—that it describes the medical officers and men of the Medical Staff Corps as non-combatants, who "under the shelter of the Geneva Cross were recognised not only as non-combatants, but as having every claim to neutrality and protection." However true this may be in the case of war between civilised nations, it certainly is not applicable to such wars as that in the Soudan or in Zululand, and we regret that Professor Ogston did not point out this, as it greatly enhances the value of the services rendered by the medical department of the army in this campaign that they have been performed under such conditions of difficulty and personal danger. The Professor enlivened his lecture by two ghastly tales of the war, not from his personal observation, but which he had "on the best authority." He concluded by stating that "he felt quite confident that the amount of interesting matter that passed under his eyes in the short time he had been away would result in a great personal benefit to him; and it would be his best endeavour that, so far as was possible, the usefulness of what he had acquired should be extended to his students at the proper time." We cannot but regret that Professor Ogston did not communicate the result of his observations on the working of the medical service, on the condition of the hospitals, the treatment of the wounded, and the general impression he received as a professional onlooker, rather than deliver a lecture which might have been as easily got up without the trouble of going to the Soudan, and which seems to have been more of a type suited to the general public than for the information of his professional brethren or of the aspirants for admission into the medical profession.

THE URINE IN OSSEOUS LESIONS.

THE condition of the urine in osseous lesions has been studied by M. Verchère, who has formulated the following propositions (*La France Médicale*, May 7th). The facts have been arranged into two divisions according as the lesion is traumatic or inflammatory. The traumatic class is further subdivided into three groups. In the first group the osseous fractures were produced by insignificant causes, and examination of the urine showed that the discharge of phosphoric acid was much above the normal; consolidation of the fracture was not hindered by this excess of phosphates. The second group is composed of cases of fracture in which union was retarded; in these there was polyuria. In the third group there was delayed union with phosphaturia, which preceded the fracture and appeared to cause it. In inflammatory osseous lesions phosphaturia is the sign of a peculiar state of the system.

THE AFTER-CARE ASSOCIATION FOR THE CONVALESCENT INSANE POOR.

THE Rev. Henry Hawkins, chaplain to the Asylum at Colney Hatch, has done us the honour, in his "Plea for Convalescent Homes in connexion with Asylums for the Insane Poor," to quote the few words we wrote in support of an important project to which we are glad to observe that public attention is at last being called, and that, too, in a practical form. On Tuesday a bazaar was opened at the Town Hall, Kensington, by the After-care Association for the Insane Poor, and by its means a fair beginning of support was entered upon. The bazaar was to have been declared open by the much-esteemed Lord Shaftesbury, but unfortunately at the last moment the state of his lordship's health prevented him from being present. In his absence the Vicar of Kensington, the Hon. and Rev. E. Carr Glyn, officiated as chairman, and in a short but effective speech inaugurated the proceedings. Mr. Hawkins described with much care the intentions and objects of the Association, and Drs. Richardson, Hack Tuke, Savage, Norman Kerr, and others supported his earnest plea. If the Association succeeds in its efforts, we shall hope before long to see a series of new institutions springing up to perform two distinct philanthropic purposes—to afford a temporary resting-place for the poor on leaving the asylum, and a home to which they can from time to time return for friendly sympathy and wise direction.

THE LONDON TEMPERANCE HOSPITAL.

ON Saturday last a grand national bazaar in aid of the funds of the London Temperance Hospital was opened in the Floral Hall by her Grace the Duchess of Westminster. The special object of the bazaar is to raise a sum of about £8000, which is needed to defray the cost of the new wing of the hospital, which is now nearly completed. Up to the present time the hospital has consisted of three wards, with a total of fifty-two beds. The new wing includes five more wards, with accommodation for nearly seventy patients, so that the total number of beds will be raised to 120. One gentleman, who desires to be known only as an anonymous donor, has given no less than £5000 to the building fund, and with such an example of liberality before them it is hoped that the friends and supporters of the institution will clear off the outstanding debt upon the new buildings. The Duke of Westminster on Saturday handed a cheque for £400 to the chairman of the Bazaar Committee, and a further sum of £1100 was taken at the stalls during the afternoon. The stalls are picturesquely arranged to represent a mediæval London street, and are liberally and handsomely furnished. The bazaar will continue open every day until and including Whit Tuesday.

IMITATIONS OF ORGANIC TISSUES.

SENOR GARCIA DIAZ has exhibited to the Athenæum of Madrid some remarkable experiments in which he has been engaged for the last two years on the artificial production of imitations of organic tissues. He has invented an apparatus which he calls the "mechanical morphogene," which consists of a hollow cylinder containing a piston for compressing objects at the base. The substance employed is a mixture of sulphate of lime and oil. With this apparatus he has produced epithelial, fibro-cellular, and alveolar tissue. According to the time occupied in the descent of the piston, the nature of its inferior surface, and the proportion of oil in the mixture, different organic forms are obtained. In a second series of experiments Señor Garcia Diaz made use of hollow bodies which, on being compressed, showed perforations in the walls, and were by various other manipulations caused to assume an alveolar texture. Round cells were also obtained by mechanical means. Polygonal cells required great pressure, as may be supposed from the positions they occupy in the human organism. He has also constructed a more elaborate apparatus, called the "pneumatic morphogene," with which microscopical preparations can be produced. In this apparatus pressure, heat, and inflation of air are combined in order to mould the outlines of the principal tissues. Varnish, from its adhering to glass, is the best substance for these investigations. With this, by means of a good deal of delicate manipulation, the most important organic tissues can be imitated, showing the author that their structure depends merely on physical conditions, no "mysterious living principle" being necessary for their production any more than for that of organic chemical substances, such as urea, which have long been shown to be capable of being built up synthetically by chemists.

DEATH OF PROFESSOR HENLE.

THE death is announced of Professor Jacob Henle of Göttingen. He was one of the last of the famous German school of scientists which flourished at the beginning of the present century, and was a most active worker all his life. When prosector and *privat docent* at Berlin, he published, in 1840, some pathological memoirs on Miasm and Contagion, Nervous Sympathy, the Course of Periodicity of Disease and Fever, subjects afterwards embodied in his more ambitious work—"Handbuch der rationellen Pathologie" (1846-1853), written when *Professor of Pathology* and Physiology at Heildelberg. In this work he foreshadows the notion of fungi playing a part in the etiology of disease. But it is in anatomy that Henle will be remembered best. His contribution to the knowledge of the structure of the kidneys completed the work of Bowman and Müller; and his famous treatise on Human Anatomy, commenced in 1855, has a world-wide reputation. In 1882 the celebration of the jubilee of his doctorate was sighalised by the publication of a volume containing anatomical and embryological memoirs by many of his old pupils, amongst whom may be named Aeby, Bardeleben, Du Bois Reymond, V. Dusch, Flemming, Friedreich, Kölliker, Kühne, Langhaus, Merkel, Waldeyer, and Westphal. In the same year Henle himself contributed to the *Archiv für Microscop. Anatomie* a memoir of the life-work of Theodore Schwann.

THE CONTAGIOUSNESS OF PHTHISIS.

IN a paper recently read before the College of Physicians of Philadelphia, Dr. W. H. Webb strongly supported the doctrine that phthisis is contagious, and brought to his aid many marked examples in literature, and some personally known to him. He described an apparatus which he had devised for filtering air, with a view to discover whether tubercle bacilli could be found in the atmosphere of places of public resort. The trap consisted of a brass cylinder containing perforated steel discs plugged by thin layers of pyroxylin; the cylinder was connected at one end with a pump, and at the other with a funnel, which was placed over the ventilating flue of the place examined. Specimens of the pyroxylin obtained in these experiments were sent to Drs. Shakespeare and Morris Longstreth for examination. Dr. Shakespeare was only able to detect one unmistakable tubercle bacillus in the four specimens sent him; but Dr. Longstreth was more successful, finding the bacilli in four out of six slides prepared from one of the specimens. Considerable difficulty was, however, met with in the research, owing to the nature of the material and the necessarily great admixture with foreign matters. Scanty as this evidence is, it does, in Dr. Webb's view, sufficiently support his thesis, and he urges that the tubercle bacillus is an undoubted fact, and that clinical observation conclusively proves that healthy individuals living in an atmosphere contaminated by the phthisical will contract the disease. He accused the "non-contagionists" of having "wilfully, unhesitatingly, and without warrant, perverted the language, even absolutely falsifying the statements, of authors they quote in support of their cause."

THE FORTHCOMING EXHIBITION OF INTRACRANIAL TUMOURS.

THE Council of the Pathological Society have announced an exhibition of and discussion on intracranial tumours, to take place at the first meeting of the Society in February, 1886. The announcement of this intention at so early a date is doubtless made with the object of giving sufficient time and notice to intending exhibitors to get their material into order. The term "intracranial tumours" is to include cysts and gummata. It is hoped that the following features will receive *consideration*:—The nature of the tumours, their situation, size, probable duration, and age at which they occur; the number of them present in the brain; and the presence and situation of secondary tumours. It is desired that the discussion may be illustrated by as many specimens as possible, as well as by pictures and diagrams. In our opinion the exhibition and discussion in question are peculiarly happy suggestions, and we congratulate the Council of the Society on conceiving so fortunate a scheme.

THE DETENTION OF LUNATICS.

A REPLY has been received from the Local Government Board by the Mile-end Old Town Board of Guardians to a letter suggesting an extension of the provisions as to the detention of alleged lunatics in certain cases, proposed to be inserted in the Lunacy Laws Amendment Bill now before Parliament. The Lord Chancellor has, the Board states, with a view to its insertion in the Bill, given notice of a clause providing that where a constable, relieving officer, or overseer has knowledge that there is within the limits of his jurisdiction a person alleged to be a lunatic, for whose care and maintenance relief appears to be requisite, he may remove the alleged lunatic to the workhouse of the union; and the master of the workhouse shall receive him therein; but no person shall be so detained for more than forty-eight hours, unless in the meantime the provisions of the Act relating to the detention of lunatics in workhouses have been complied with.

ENORMOUS CALCULUS.

WE understand that a calculus far exceeding in size that mentioned in THE LANCET of the 2nd inst. as having been extracted by Sir Henry Thompson has recently been removed from the human bladder by Mr. Rivington at the London Hospital. The calculus weighed (avoirdupois) 1 lb. 9 oz. 2 dr. when removed. It weighs, now that it has been put together and in dry state with hollow centre, owing to absence of nucleus and débris, 1 lb. 6½ oz. (avoirdupois). The dimensions are thirteen inches in circumference lengthwise, and ten inches transversely.

LICKING ADHESIVE STAMPS AND ENVELOPES.

THIS is a perilous practice, against which the public needs to be put on its guard. We have seen bad consequences ensue from the habit, which is a very common one. Those who are frequently thus moistening the gum on adhesive surfaces suffer from local irritation, sore tongues, and the like, while every now and again we hear of special propagation of disease by the habit. A curious illustration of the way in which disease may be communicated was recently brought under our notice. An envelope received from a person who habitually took large quantities of morphia hypodermically was reclosed by the person who opened it by licking the adhesive surface, with the result of making him violently sick. The mere touch of the tongue of the taker of morphia had rendered the gum intensely nauseous. If this could happen, obviously there must be grave peril of the transmission of disease by such means. It is not likely that many persons would even incidentally re close an envelope in this way; but the incident may serve to show how desirable it is not to run the risk of even taking in the impurities of new adhesive matters from stamps and envelopes. It is very easy to avoid the practice The danger only needs to be pointed out.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

AN election for a member of Council, in the room of Dr. Mapother, resigned, took place on Tuesday, the 19th inst., when Dr. Edward Hamilton, Professor of Surgery in the Medical School of the College, was elected without opposition. The annual elections for President, Vice-President, Secretary, and Council will be held on Monday, June 1st, when Dr. Cameron will be advanced to the Presidency, and most probably Mr. William Stokes will be elected Vice-President.

CHOLERA "VACCINATION" IN ALCIRA.

IN a letter in a Spanish medical journal from Alcira, the writer says that he has just proved the existence of Koch's comma bacilli in the stools of a case he has seen. He mentions also that the only two boys in an institution in that place who were not "vaccinated" by Dr. Ferrán at his first visit have been attacked by cholera, and that this fact has produced such a profound sensation in the town that all the inhabitants have the greatest faith in Ferrán's preventive. The same journal states that Dr. Ferrán has been dismissed from his post in charge of the hospice at Tortosa by the municipal authorities, who probably think that his time is so fully occupied in other ways that he cannot devote the attention to the local infirmary that is required, and that could be given by a less eminent medical man.

THE SALVATION ARMY AND LUNACY.

THERE has been a slight skirmish or interchange of shots between an outpost of the Salvation Army and a medical man on the subject of the proceedings of the army and lunacy. Surely "General" Booth does not need to be told that there is such a thing as religious mania, and that the sort of excitement his propaganda produces is likely to act injuriously on hysterical females and excitable males. Emotional perturbation is always mischievous. The weak feel it more than the strong. Every description of "revival" produces a crop of insanity. It is to unstable and excitable nervous centres this sort of enthusiasm appeals, and out of the multitude affected there must be some who break down.

EXTIRPATION OF THE GALL-BLADDER.

AT the Brussels Academy of Medicine Dr. Hyernaux reported a case of hepatic colic caused by gall-stones, in which Dr. Thiriar had extirpated the gall-bladder. Although the patient recovered, the majority of the speakers considered the operation undesirable and unnecessary. They thought that it ought to be borne in mind that this affection sometimes underwent a spontaneous cure, and they advised that it should be treated by a carefully regulated dietary and medicine, and that recourse should not be had to an operation fraught with such serious risk.

MEDICAL LEGISLATION.

THERE is reason to believe that the Government have some intention of introducing a Medical Bill after Whitsuntide.

THE CHOLERA.

WE are glad to be able to give an emphatic denial to the report that cholera has broken out in Durham. Not a single case has occurred in that city.

THE Select Committee appointed to consider the law relating to the control over telephone, telegraph, and other wires, in their report which has just been issued state that they, having heard evidence from the Post Office, the telephone companies, the various local authorities of the metropolis, the corporations of some of the leading provincial towns, and private owners and occupiers, have come to the conclusion that the risk of danger to the public from overhead wires has been very greatly exaggerated. At the same time they are of opinion that the probable development of the telephonic system makes it desirable that there should be some legislation on the subject.

PROFESSOR BURDON SANDERSON, on the 15th inst., delivered a lecture at the Royal Institution on "Cholera, its Causes and Prevention"; in the course of which he gave a short history of the manner in which at various periods the disease had spread, and stated that those who resided in the west and north of London need have no fear as to cholera if it fixed itself again in the east of the metropolis. He, however, predicted that if the disease intended to attack London this year it would long ago have been on the march.

AT a recent meeting of the Ballinrobe Dispensary Committee, it was stated that in the absence of the local medical man the porter of the workhouse attends the dispensary, dispenses medicine, extracts teeth, and vaccinates children. To make things worse, he is an illiterate man, unable even to read a label. After a long discussion, it was resolved that the porter be dismissed, and that the Local Government Board be called upon to hold a sworn inquiry into the circumstances.

A SPECIAL prize has been awarded by the Academy of Medicine of Paris to Dr. Murrell, Lecturer on Pharmacology and Therapeutics at the Westminster Hospital, for his introduction of nitro-glycerine as a remedy for angina pectoris and allied diseases. A sum of 500 francs has been awarded to Dr. Henri Huchard of Paris for his work entitled "Les Angines de Poitrine."

THE district of Pensa, in Russia, has decided to grant a pension to the families of its medical officers who have died from cholera. This is without reference to their length of service. The sum of 900 roubles is to be granted yearly to the families of qualified medical officers, and 180 roubles to those of members of the subordinate medical service.

DR. WYCHERLY, High Sheriff for the city of Cork, is to receive the honour of knighthood, in appreciation of the part he took in the reception of the Prince and Princess of Wales. Dr. Banks also is spoken of as likely to be the recipient of a baronetcy.

DR. FREDERICK TAYLOR having been elected Physician to Guy's Hospital, Dr. W. Hale White has been appointed Assistant-Physician to that institution.

THE Birmingham Hospital Saturday collection had reached the unprecedented amount of £6325 0*s.* 7*d.* up to the close of bank hours last Monday, showing an increase of £393 on last year's total.

DR. PETROV, Professor of Pathological Anatomy in the University of Kasan, Russia, has resigned, and the Faculty has nominated the prosector, Dr. N. Ljubimov, as his successor.

TWO fatal cases of cholera are stated to have occurred at Marseilles.

CHOLERA CONFERENCE AT BERLIN.

(Concluded from p. 913.)

THE fourth sitting, on May 7th, was opened by a demonstration by Professor Koch of some inoculations with Brieger's bacillus, and of pure cultures of comma bacilli obtained from the intestines of guinea-pigs previously shown. He then resumed the debate, which he said had simplified comprehension of the subject, for the points of difference between himself and Professor von Pettenkofer were diminished by the latter's admission of the fact of individual immunity and the influence of traffic in spreading the disease. Nor did he himself deny that humidity of soil has some influence, especially in the surface layers, where organic matter decomposes; but this condition is only one, and not the foremost, of many factors. Local immunity is not explained by it solely, being due to very complex conditions, as exemplified in the case of Lyons. Mooltan, a town of the desert, is almost the sole place in India that enjoys immunity. He gave further instances of the risk of traffic with the cholera sick, and stated that the dangers of ship traffic do not depend on the extent of an epidemic on individual ships, but on the number of vessels attacked by cholera, and this is comparatively large. Turning to the third point proposed for discussion, he said there was no authentic fact of the atmospheric transmission of cholera. It might occur exceptionally, but as a rule the atmosphere only influences a cholera epidemic by the fact that the virus retains its power for a longer period in moist air, and speedily perishes in dry air. The soil may influence the spread of cholera by its physical property. It had been said that a clay soil was to a certain extent protective, but he cited instances showing that this was not invariably the case. He showed by various examples from India, Egypt, Paris, Genoa, and Naples that the subsoil water is no index of the diffusion of cholera; it is the various kinds of putrefaction in the superficial layers that are the important conditions in soil. Of the three factors, *x*, *y*, and *z*, which Professor von Pettenkofer declared some years ago to be necessary for an epidemic, was it the *x* or the *y* which is represented by the bacillus? Drinking water is of some importance; a certain percentage of individuals are protected from cholera by pure water, as was seen by a reference to plans and tables from Calcutta (especially Fort William) and from Bombay, Madras, Nagpore, Pondicherry, Alexandria, and Cairo.

Dr. GÜNTHER said that in Saxony during the epidemics of 1865, 1866, and 1873 the mortality among medical men, nurses, and gravediggers was not higher than the mean of the whole population; there was in 1865 and 1866 a higher rate amongst those who washed the linen of cholera subjects, but not in 1873. He gave examples from Elsterberg and the Gerbergasse at Dresden as apparently in favour of the protective nature of a clay soil. In Saxony the height of the epidemic of 1873 corresponded with the acme of the ground temperature at a depth of one metre.

Professor von PETTENKOFER read a paper on the Drinking Water Theory and the Immunity from Cholera of Fort William in Calcutta. He pointed out that according to Dr. Mouat' the disappearance of cholera from Fort William was brought about not merely by the new water-supply, but by other extensive sanitary measures, including a thorough sanitation of the soil. The same obtained in other places, where an improved supply of drinking water has been regarded as the cause of the disappearance of cholera, for more careful scrutiny showed that the observation had been defective, or that many other hygienic measures had co-operated. Pure water *per se* was not a specific prophylactic against cholera, and he deemed it essential to assert this because people have been content to believe that with the introduction of pure water enough had been done, and therefore to neglect the more important matter of sanitation of the soil.

The final sitting took place on May 8th, when the debate on points 2 and 3 was resumed by Professor von PETTENKOFER, who said that when he proposed to regard the subsoil water as the index of cholera, he had not meant especially the rise and fall of the subsoil water, but only the variations indicated by the hydrometer in the humidity of the soil overlying the water. It was only such variations that were of etiological importance, and only those wells could be employed for measurement which did not change their level from other causes—e.g., not those depending solely on the levels of the nearest river. He postponed his reply to Professor Koch's criticisms to another opportunity, as he had not at hand data referring to many of them, and time would not permit of his entering upon them all.

Dr. B. FRAENKEL said that, since it had been clearly shown that the winter latency of an epidemic could be explained by the known vital tenacity of cultures of the comma bacillus, there only remained of the reasons advanced by Professor von Pettenkofer against the view that the bacillus is the cause of cholera this—viz., that the local and periodical characters of cholera epidemics are not to be explained by the vital peculiarities of the bacillus. But, once admit the bacillus to be the cause of cholera, and this difficulty disappeared. It traces the origin of an epidemic to something external to the human body, with certain special conditions, local and periodical, in addition. He asked Professor von Pettenkofer if, in what is known of such conditions, there are facts which preclude the view of the comma bacillus being the cause of the disease.

Professor von PETTENKOFER said that such conditions depend upon (1) the physical character of the soil, permeability; (2) its humidity and variations in this; (3) its impregnation with organic matter. He would willingly recognise the comma bacillus, and any bacillus considered by bacteriology to be the cause of cholera, as the special cholera virus, and abandon his doubts, if it were proved that the micro-organism answered to epidemiological facts upon local and periodical conditions. In that case it must, like the malarial virus, have some relation to the soil.

Professor VIRCHOW said that when Professor von Pettenkofer commenced his studies on cholera the idea was in vogue at Munich that a fungus was the cause of cholera; but the notion was corrected by Thiersch's experiments on white mice; and it was thought that the virus was formed later in the dejecta. Although these experiments may have been erroneous, yet Professor von Pettenkofer had not given up the notion of this late development of the cholera germ. In the inquiry into the various conditions in which fæcal matters are found, the soil very naturally occupies the foreground; and from this point of view Professor von Pettenkofer's labours had thrown much light. But whilst fully acknowledging their merit, Professor Virchow could not understand their exclusive standpoint. Why should the material that causes cholera, and that is present in the soil, be not also capable of passing into drinking water? Theoretically there was nothing opposed to that. Practically the question is reduced to the somewhat rough-and-ready one as to whether an improved water-supply can limit cholera epidemics; but there are many kinds of impurity in water. In reference to Professor von Pettenkofer's objection to the experience gained on this head—e.g., the facts Professor Koch related about Fort William that other improvements in sanitation occurred at the same time,—it must still be asked whether these other changes were also of value. In introducing a good supply of water, drainage was also improved, and both had undoubtedly a favourable effect. It is with cholera as with typhoid. Thus at Halle a sudden and permanent reduction in the frequency of typhoid followed the introduction of drainage, and buildings supplied with good drinking water have remained free from the disease. Yet it by no means follows that typhoid and cholera have nothing to do with the soil. It has been proved that the comma bacillus can exist in water; and were another fungus alleged to be the cause of cholera, the same must be proved of it. By subsoil water he did not understand, with Professor von Pettenkofer, the water that soaks through from the surface. Subsoil water is an entity, and it is impossible to split it into different kinds. He had always maintained that fungi got their nutriment only in the uppermost layers of the soil, and this was important, since every kind of impurity could not be drained off. Dr. Babes had shown that in the struggle for existence the comma bacillus is speedily overborne by putrefractive bacteria; and, therefore, there must needs be varied and special circumstances for it to flourish, and further researches upon water on linen, &c., were required to elucidate tnem. Nor could personal predisposition to cholera be disputed, and in this connexion it must be remembered that the attack of cholera usually occurs during digestion, when living organisms might be passed into the bowel without being long in contact with the gastric juice. The atmosphere must also play some part, as in the diffusion of particles in the unpacking of *linen and their conveyance to the mouth.*

Professor KOCH reserved his arguments against Professor von Pettenkofer's views to another opportunity.

The fourth point was then discussed—viz., on the practical measures for attacking cholera. These were summarised by Professor KOCH as follows:—1. Measures for the direct destruction of the infective material, disinfection of dejecta, destruction or disinfection of linen, &c. 2. Sanitary works for carrying the virus away, drainage, good water-supply. 3. Competent supervision of communities for the speedy diagnosis of the earliest cases, in order to nip the epidemic in the bud; the sick must be isolated or so guarded as to prevent contagion. Infected houses to be vacated by the healthy, who must be supervised. 4. The instruction of the public so as to allay their fears, and make them aware of *the dangers of uncooked food,* unboiled well water, with particular warning against the use of infected linen.

Dr. GÜNTHER said one difficulty was to determine what water was dangerous and in what circumstances wells should be closed.

Professor KOCH said that no general rule could be laid down; but it was essential not only to ascertain the chemical characters of the water, but to determine how many and what kind of micro-organisms are present in it.

Dr. GÜNTHER alluded to the supervision of railway travellers, its difficulties and impossibilities, and its doubtful utility.

Professor KOCH said the regulations in this regard must be dictated in the humanitarian sense, as needed for the protection of the sick and in the interest of his companions.

Dr. S. NEUMANN pointed out that premonitory diarrhœa is excluded from control, and must yet be regarded as cholera.

Professor KOCH agreed, provided that comma bacilli were present in the dejecta.

Dr. KÖHLER, in view of the strict control over ship traffic, would like to support a practicable revision of railway traffic without disturbing travellers, so that the charge may not be brought against officials that nothing is done for the protection of people.

Dr. MEHLHAUSEN urged the importance of cleansing the water-courses, especially the smaller ones; and Dr. EULENBERG illustrated this point by instances of the spread of cholera through the Salzbach at Wiesbaden and the Schwarzbach at Liegnitz.

Professor VIRCHOW called attention to Bacon's portable disinfecting apparatus, and mentioned that the Berlin Town Council were about to erect special disinfecting establishments. Isolation of the sick was necessary, but a land quarantine would be impracticable with our complicated travelling system.

Professor KOCH laid stress on the disinfecting property of drying. His observation that the comma bacillus is rapidly killed by drying has been confirmed on all sides. Where carbolic acid and disinfection by steam were inapplicable, the virus could be killed by drying—e. g., in the case of furniture and dwellings. In many cases fresh lime-washing of walls would suffice. In reply to Dr. Pistor, he said that corrosive sublimate destroys the bacilli, but he did not recommend it as a disinfectant on a large scale.

Professor von PETTENKOFER stated that measures of isolation, disinfection, &c., did not determine the mildness or severity of an epidemic; but he admitted that measures must be taken to calm the public mind.

Dr. KERSANDT warned against *laissez-faire* on the part of officials on the outbreak of an epidemic. The State interest demanded that the public should feel that protective measures were taken, for that was the best way of calming them; and the State could do much to protect against cholera invasion. The sick must be isolated as far as possible, the water-supply supervised, and no measures which experience proves of value be neglected.

Professor VIRCHOW said that in Berlin in 1848-9 the view was held, and acted upon, that cholera was not contagious. The mortality was 12 per 1000, the highest experienced in Berlin. More was to be gained as guiding to what was to be done by the experience obtained from the individual case than the observation of the epidemic as a whole.

Professor MEHLHAUSEN spoke of precautions in the interment of cholera subjects, and, no member offering any further remarks, the conference was brought to a close by Professor Virchow thanking the foreign members for their attendance and their contributions, which was acknowledged by Professor von Pettenkofer, who said they had a common aim, *and could meet to pursue it although their opinions might* differ.

ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

A MEETING of this Association was held on Wednesday last, at 5.30 P.M., in the rooms of the Medical Society, Chandos-street, W. The chair was taken by Mr. George D. Pollock, and the meeting was well attended. The chairman in opening the proceedings said that the Committee of the Association had endeavoured to carry out the instructions intrusted to them. They had had one conference with a deputation of the Association of Members, at which the chief subject under consideration was the mode of election of members of Council. This question was patiently discussed on both sides, and the conclusions at which the Committee of the Association of Fellows had arrived were embodied in the resolutions which had been submitted by post to the members of the Association. Speaking of the deputation of Fellows from the Association to the Council of the College, Mr. Pollock said the deputation was fairly and kindly received, but the printed report which had been circulated showed how little was gained, by the conference with the Council of the Royal College of Surgeons. And although on the occasion of the conference he (Mr. Pollock) *specially addressed the chairman of* the sub-committee on the point that no Charter should be applied for without a further meeting between the Association of Fellows and the Council of the College, and had received the answer that this request should be carried out, yet the Council did not think it necessary to comply with that request or to treat it with any more courtesy than by a notice given to the secretaries of the Association that the Council had proceeded to the Home Secretary with a view of obtaining the new Charter. Having this state of affairs in view, the Committee of the Association had consulted together and had proposed to address a letter to the Home Secretary praying him not to approve the new Charter before the Fellows of the said College had represented their views to the Home Office, and before the President of the Association should have explained the objects which the Association had at heart.

A sub-committee for the purpose of drawing up the letter was nominated, and the letter was to read as follows:—"We beg to bring to your notice the following resolution, unanimously adopted at a meeting of the Committee of the Association of Fellows of the Royal College of Surgeons comprising at least one-fourth of the whole number, *held on* May 11th, 1885—viz., 'That a letter be addressed to the Secretary of State for the Home Department praying him not to approve of the amended Charter about to be applied for by the Council of the Royal College of Surgeons of England until the Fellows of the said College have had an opportunity of representing their views in the matter.' We are authorised on behalf of the Association to state that the views entertained by the Fellows of the College are in many important respects opposed to those held by a majority *only of the Council,* which consists of only twenty-four Fellows. In preferring this request, we would commend to your notice that we have good grounds for believing that no Charter will be acceptable to the body of Fellows and Members of the College which does not include the recommendations proposed by the Association of Fellows, but many of which have been rejected by the Council of the College. We beg to enclose a copy of these recommendations with the replies of the Council." Signed by G. Pollock, A. Willett, J. Tweedy, and W. Bruce Clarke.

The meeting unanimously expressed its approval with the terms of the letter. The next business was the discussion of the following resolutions which had been drawn up by the Committee of the Association:—

1. That it is inexpedient for the Association of Fellows to unite with the Association of Members in its demand for representation. 2. That if, however, the Members should succeed in obtaining the right to elect members of Council, it is desirable that the existing rights of the Fellows should be adequately protected in the new Charter.

Some discussion took place on the nature and consequences of the conference between the Association of Fellows and that of Members. The secretary, Mr. Bruce Clarke, said that he had been in communication with Mr. Steele, the secretary of the Association of Members. The proposition "That the Fellows and Members (of the College) unitedly shall elect the Council, but no one shall sit on the Council unless he be a Fellow or a Member of ten years' standing," was the principal subject which the Committees of the two Associations had discussed. The last letter received from the secretary of the Association of Members asked what terms the Association of Fellows would be agreeable to accept. Mr. Alban Doran, Mr. Butlin, Mr. Gant, Mr. Barnes, and others spoke on the question, and the first resolution was moved and seconded, when

Mr. John Tweedy proposed as an amendment the following:—"That in the opinion of the Association of Fellows it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education, if Members of the College were empowered to take part in the election of members of Council, provided, firstly, that no Member shall be eligible to vote until he has been such Member for a period of at least ten years; and, secondly, that the number of members of the Council elected by the Members of the College shall not exceed one-third of the whole Council." In proposing this amendment, Mr. Tweedy said that he had purposely abstained from conferring upon it with the other members of the Committee of the Association of Fellows. He confessed that, had the Members of the College never raised the question of direct representation on the Council, he should not have thought of claiming such representation for them. Small electoral bodies had a certain amount of convenience, and he considered that there was such a body in the order of Fellows of the College. Still, as we were brought face to face with a great question for reform, we ought not to shrink from it. It must be remembered that all these attempts at reform had come about us as the result of the general meeting of Fellows and Members held in March, 1834. Notwithstanding the representations made from all quarters to the Council of the College, this autocratic body had seen fit to reject all proposals and had simply increased its own autonomy. Speaking next of the rights of Fellows and Members respectively, Mr. Tweedy said that no doubt the President and others, his seniors, could remember the heartburnings that existed when the order of Fellows was created, and some would know as a matter of history the disgraceful circumstances under which the College originated. The old Corporation of Surgeons had been guilty of many acts of illegality, and parliamentary influence was brought to bear, happily without success, to condone these illegal acts. But though Parliament rejected these overtures, yet the part of courtly intrigue was well played, for George III. was prevailed upon to grant a Charter in which the Members of the College were entirely ignored. The Council was self-elective, and the Members of the College were left out of consideration altogether. After forty-three years of this disgraceful existence, the creation of the order of Fellows must be looked upon as a distinct advance, though it was a most arbitrary act, for the friends and relatives of members of the Council were made Fellows without any special claims. From that time to this nothing had ever been done for the Members, who were an increasing and intelligent body of men. They carry on the hard work of the medical profession; they were the ministers of surgical life. So that he thought that direct representation on the Council would not only be conducive to the welfare of the profession, but the Members of the College would feel that they were drawn to the College by bonds of interest and affection. And if these things came about, it seemed to him that the College of Surgeons would have a more brilliant career than it had ever had yet. He would limit the eligibility of the Members to those of ten years' standing, and this proposal would practically reduce the constituency of the Members to between three and five thousand, which would be composed of staid practitioners and men of mature intelligence. Feeling that their influence in the Council should be limited, he had introduced the final clause in his amendment.

Mr. Alban Doran seconded this amendment, which he considered was based on sound principles. In moving the amendment, he thought Mr. Tweedy had shown himself to be a practical politician, for he faced matters as they were likely to turn out, and not as one should wish them to be.

Mr. Oliver Pemberton accepted the amendment with a slight reservation to the effect that the Members should hardly be allowed to swamp the Fellows in the Council. He considered that the number of Members voting should not exceed the number of Fellows voting.

Mr. A. Willett also approved of the substance of the amendment, but regarded it rather as a rider or addition to the resolutions which had been submitted to the meeting. The letter read by the secretary from Mr. Steele showed that the Association of Members were willing to talk over the matter so that a common *modus vivendi* could be maintained between the two Associations.

Mr. John Tweedy said that he had made his proposition as an amendment on account of the wording of the first resolution.

Mr. Willett, Mr. Butlin, Mr. Macnamara, and others contended that there was really nothing in the proposed resolutions which could be construed as antagonistic to a mutual understanding between the Associations.

Mr. J. Wickham Barnes thought that a second interview should be had with the Association of Members before any details were arranged.

It was urged, however, that the amendment might be regarded as a basis on which the committees of the two Associations could meet and discuss.

Mr. Pollock suggested that the first resolution should be verbally altered.

Mr. R. Davy said that he was horrified on reading the first resolution, which began in so unsympathetic a manner as "that it is inexpedient," &c. He believed in the old-fashioned proverb—"Vis unita fortior." It was not long ago, when danger threatened the College, that Mr. Trimmer, the secretary, had no hesitation in applying by letter to all Members. If Members were applied to in times of war, surely they had a right to be applied to in times of peace. His arguments were used in favour of a common platform, and the establishment of a common fellowship; and he thought the question was pretty much the same as that which had been fought out throughout the political world recently.

Mr. Willett and Mr. Tweedy then consulted, and the following amended resolution was put to the meeting and unanimously carried:—"That whilst it is inexpedient for the Association of Fellows to unite with the Association of Members in its demand for universal suffrage and for equal representation on the Council, yet, in the opinion of the Association of Fellows, it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education, if Members of the College were empowered to take part in the election of members of Council, provided that no Member shall be eligible to vote until he have been such Member for a period of at least ten years."

After some discussion, it was moved by Mr. Tweedy, and seconded by Mr. J. W. Barnes, that a copy of the resolution be forwarded to the Association of Members with a view of informing them of the policy adopted by the Association of Fellows as a basis on which the committees of the respective Associations might take conference. With such a policy, it was felt that the Associations might go to the Home Secretary, confident in their combined cause.

The ceremony of laying the foundation-stone of the Northern Hospital, Winchmore-hill, for the reception of fever and small-pox cases above the pauper class, took place on the 16th inst. The building, which is in the modern style, is of brick, and consists of two storeys, with accommodation for 512 patients and the necessary officers and staff. The cost is estimated at £13,580.

SANITATION IN THE STRAITS SETTLEMENTS.

THE year 1884 was a healthy one in all the three Settlements. There was no epidemic of any kind, and the comparative freedom from contagious disease, even in sporadic forms, must be a subject of much congratulation to the various medical officers engaged in the institutions. The only cases of cholera, or choleraic diarrhœa, reported as having occurred in Singapore town took place in the Rochor district during December, and immediately following an unusually heavy rainfall. The persons seized occupied huts situated on the edge of the Kallang river, the water from which had been used for drinking purposes. Doubtless the heaviness of the fall had stirred up much organic débris from the sides and bed of the river, which had contaminated the water to a fatal degree. Four cases occurred in two days, all of which ended in death. The inhabitants were forbidden to drink from the river, town water was supplied to them, and the disease was at once arrested. It is a fact worthy of observation and beyond dispute, that the cases of cholera which now occur in Singapore do so almost always in a locality where town water has been found impossible or difficult to be procured. The drainage of the town generally is improving year by year, though in certain districts much remains to be done. There were admitted into the several civil hospitals in the Settlements 740 Europeans and 14,357 natives, which, together with 28 Europeans and 1030 natives who remained at the close of 1883, gives a total of 768 Europeans and 15,387 natives treated during the year. The number of vaccinations performed was 2341 at Singapore, 2436 at Penang, 3583 in Province Weilesley, and 2801 in Malacca. Comparing the mean temperature of the different stations, it is interesting to note that Singapore recorded the lowest temperature, Malacca next, then Penang, and lastly Province Wellesley; the variations were very slight, the difference between the highest (83°) and the lowest being only 1·9°. The highest temperature recorded during the year was 96·5° in Province Wellesley. At Singapore the total fall of rain during the year was 80·15 inches, against 71·13 inches in 1883; at Penang, 87·56 inches, against 87·74 inches; at Province Wellesley, 77·53 inches, against 81·73 inches; and at Malacca, 84·11 inches, being 7·08 less than that of the preceding year.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5767 births and 3487 deaths were registered during the week ending the 16th inst. The annual death-rate in these towns, which had been equal to 23·4, 21·1, and 20·2 per 1000 in the preceding three weeks, was last week 20·4. During the first six weeks of the current quarter the death-rate in these towns averaged 22·2 per 1000, against 23·3 in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 10·9 in Brighton, 14·2 in Bolton, 15·1 in Derby, and 15·5 in Bristol. The rates in the other towns ranged upwards to 25·0 in Sunderland, 27·7 in Manchester, 30·3 in Newcastle-upon-Tyne, and 33·4 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 449 and 481 in the previous two weeks, declined again to 463 last week, and included 143 from measles, 126 from whooping-cough, 50 from small-pox, 45 from "fever" (principally enteric), 37 from scarlet fever, 33 from diphtheria, and 29 from diarrhœa. No death from any of these principal zymotic diseases was returned last week either in Norwich or in Derby, whereas they caused the highest death-rates in Sunderland, Blackburn, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Birkenhead, Manchester, and Newcastle-upon-Tyne; from whooping-cough in Plymouth, Oldham, and Blackburn; from scarlet fever in Cardiff and Sunderland; and from "fever" in Salford, Cardiff, Sunderland, and Plymouth. The 33 deaths from diphtheria in the twenty-eight towns included 21 in London and 2 in Brighton. Small-pox caused 62 deaths in London and its outer ring of suburban districts, exclusive of 30 deaths of London residents in the hospital ships and camp at Darenth. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1282 and 1361 on the preceding two Saturdays, further rose to 1364 at the end of last week; the admissions, which had been 246, 354, and 315 in the previous three weeks, declined to 211 last week. The Highgate Small-pox Hospital contained 69 patients on Saturday last, 10 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding five weeks from 512 to 287, were last week 291, and 60 below the corrected weekly average. The causes of 82, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Sunderland, Brighton, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Bristol, Sheffield, and Norwich.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily declined in the preceding six weeks from 25·0 to 20·6, rose again to 23·4 in the week ending May 16th, and exceeded by 3·0 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 17·2 and 17·5 in Edinburgh and Leith, to 25·5 in Paisley and 29·7 in Glasgow. The 570 deaths in the eight towns included 24 which were referred to whooping-cough, 19 to measles, 19 to diarrhœa, 8 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 4 to scarlet fever, and not one to small-pox; in all, 79 deaths resulted from these principal zymotic diseases, against 81, 64, and 55 in the three preceding weeks. These 79 deaths were equal to an annual rate of 3·2 per 1000, which was 0·3 above the mean rate from the same diseases in the twenty-eight English towns. The 24 fatal cases of whooping-cough showed a further decline of one from the numbers in recent weeks, and included 9 in Glasgow, 6 in Dundee, and 3 in Greenock. The 19 deaths from measles, however, showed an increase, and included 18 in Glasgow. The 19 deaths attributed to diarrhœa showed a considerable increase upon recent weekly numbers, and exceeded by 7 the number returned in the corresponding week of last year. Six of the 8 deaths from "fever," 4 of the 5 from diphtheria, and all the 4 from scarlet fever, occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 124, 117, and 95 in the preceding three weeks, further declined to 95 last week, and were 53 below the number returned in the corresponding week of last year. The causes of 82, or more than 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 34·0, 33·5, and 28·5 per 1000 in the preceding three weeks, rose to 35·0 in the week ending the 16th inst. During the first six weeks of the current quarter the death-rate in the city averaged no less than 32·8 per 1000, the mean rate during the same period not exceeding 20·0 in London and 18·5 in Edinburgh. The 237 deaths in Dublin last week showed an increase of 44 upon the number in the previous week, and included 14 which resulted from measles, 7 from whooping-cough, 5 from diarrhœa, 4 from scarlet fever, 3 from "fever" (typhus, enteric, or simple), 1 from diphtheria, and not one from small-pox. Thus 34 deaths resulted from these principal zymotic diseases, against 40 and 22 in the preceding two weeks; these 34 deaths were equal to an annual rate of 5·0 per 1000, the rate from the same diseases last week being 2·9 in London and only 0·4 in Edinburgh. The fatal cases of measles in Dublin, which had been 17 and 12 in the previous two weeks, rose again to 14 last week. The 7 deaths from whooping-cough exceeded the number in any recent week, and those from scarlet fever, "fever," and diarrhœa were also more numerous than those returned in the previous week. Six inquest cases and 7 deaths from violence were registered within the city; and 76, or nearly a third of the deaths, were recorded in public institutions. The causes of 35, or nearly 15 per cent., of the deaths registered during the week were not certified.

SALFORD HEALTH BULLETIN.

The Quarterly Health Bulletin relating to the first three months of this year affords most satisfactory evidence of the health condition of the borough of Salford. The annual death-rate did not exceed 20·7 per 1000, which was 3·9 below the rate in the corresponding periods of the five preceding years; it was also 2·0 per 1000 below the mean rate that prevailed during last quarter in the twenty-eight large English towns. The information bearing upon the notification and isolation of cases of infectious disease shows the result of energetic sanitary organisation carried out with tact, the beneficial effect of which upon the health of the borough cannot well be over-estimated. The calculated death-rate of children under five years of age in the last quarter was 53·0 per 1000 living, ranging in the four registration sub-districts from 33·6 in Broughton to 72·9 in Greengate. No more conclusive evidence is needed that the sanitary authority of the borough should look for further health progress in Greengate registration sub-district. We should be glad to see other large towns following the example of Salford in the publication of Quarterly Health Bulletins containing similar statistical information, reflecting in so trustworthy a manner the health of the population.

THE SERVICES.

Among the officers who left Sawakin in the *Jumna* on the 17th inst., sick, was Surgeon-Major J. J. Crean. Staff Surgeon P. A. Hayes and Surgeons Hay and Mander are reported as sick on board the hospital ship *Ganges*. Amongst the officers who left Sawakin for England on the 15th inst. were Staff Surgeon C. J. Holmes and Surgeon W. C. Beevor. The following officers have left Egypt for England invalided: Surgeon-Major J. Kinahan and Surgeon C. E. Faunce.

WAR OFFICE.—*Army Medical Staff*: Brigade Surgeon George Langford Hinde to be Deputy Surgeon-General, vice Edward Malcolm Sinclair, M.D., placed on temporary half-pay; Surgeon-Major William Temple, M.B., V.C., to be Brigade Surgeon, vice George L. Hinde; Surgeon-Major James Shand Duncan, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Charles Wyat Watling is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Edward Harford Lloyd, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon; James B. Clarkson (L.R.C.P. & S. Edin.), Lieut. 19th Lancashire Rifle Volunteers, has been appointed to a commission in the Reserve of Officers.

"Audi alteram partem."

THE ELECTION OF COUNCILLORS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—It may simplify the action of the Fellows at the coming election for Councillors at the College of Surgeons if you will allow me to say that it is neither my wish nor my intention to offer myself for re-election.

I am, Sir, yours obediently,

Cavendish-place, W., May 16th, 1885. JOHN ERIC ERICHSEN.

"PNEUMOTHORAX FOR HÆMOPTYSIS."

To the Editor of THE LANCET.

SIR,—In an annotation last week you were good enough to speak favourably of my plan of producing artificial pneumothorax. Will you allow me a brief space to point out some advantages which this plan offers over the method by free incision besides the ones you referred to. By using a fine hollow needle the operation can be done without moving the patient in his bed, without causing any pain, and without chloroform, therefore circumstances of great moment when the patient is enfeebled by disease or loss of blood. Moreover, the pneumothorax can be induced very gradually, and can be suspended or pushed on at the option of the operator. If it seemed desirable, very considerable pressure could be brought to bear on the lung; on the other hand, if for any reason it were thought advisable, by merely reversing the process, the injected air could be immediately withdrawn, and the *status quo ante* brought about. Once the chest-wall is incised we lose further control over its mechanism, and cannot undo our operation if for any reason it fails to fulfil our requirements. You justly point out the limited application of such a procedure, and yet if it can be undertaken without risk or danger, and if the operation can, so to speak, be undone without any difficulty, it may come to be tried at an earlier stage before adhesions to the chest-wall, solidification or other mechanical causes render the lung incapable of collapsing. Such a plan appears to me thoroughly rational and full of promise; it is but an extension of the principle of physiological rest to a diseased organ incapable of getting rest in any other harmless way. Where there are small cavities or aneurysms it is not improbable that a cure may be obtained in a few cases, for it would bring the walls of such cavities into contact with each other and so promote adhesion between them, and obliteration.

I am, Sir, yours faithfully,
ROBERT WM. PARKER.

Old Cavendish-street, W., May 18th, 1885.

PERSONAL EXPERIENCE OF COCAINE AS AN ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—As I believe I am the first member of the profession who has undergone a serious operation under the influence of the new anæsthetic, I feel that I ought to place my experience on record.

About eight years ago, being then in my sixty-second year, and finding that the sight of my right eye was not so good as formerly, I consulted Sir William (then Mr.) Bowman, who informed me that I was suffering from cataract. Finding my left and best eye failing me considerably during the past autumn and winter, I determined to have the right eye operated upon, and with this object placed myself under the care of Dr. Bell Taylor of Nottingham. As I have always had a strong tendency to squeeze the lids forcibly together on slight provocation, and instinctively resent in an exaggerated degree anything like the impact of a foreign body, even of a drop of water, I fully expected it would be necessary to inhale some general anæsthetic, although I dreaded the possible ill-effects of the vomiting and retching which either ether or chloroform might occasion. I had heard, of course, of the employment of cocaine in order to annul sensation during the removal of foreign bodies from the surface of the eyeball and in other slight operations, but never for one moment expected that it would suffice for the extraction of cataract in a hypersensitive individual like myself. The doctor, however, assured me that I should not feel it, and, to my great surprise, I found that this statement was literally true. The solution of cocaine was applied to my eye three times at intervals of five minutes before the operation, and each step of the operation was explained to me by Dr. Taylor as it was successively accomplished; the preliminary incision was completed without pain, as was also the excision of a small portion of the iris made in the upward direction—a satisfactory answer it appears to me to the query, Does cocaine affect deep-seated parts?

I can truthfully affirm that the whole affair was painless, that the cataract was removed without pain, that I have had very little pain or discomfort since, and can now, little more than a fortnight after the operation, see objects distinctly, make out words of small print, and am improving every day.

You have had satisfactory evidence of the value of cocaine before, but I venture to think none so conclusive as this which I have now to offer.

I am, Sir, your obedient servant,

Staindrop, Darlington. WM. COPELAND, M.R.C.S.

THE PROSECUTION OF IRREGULAR PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—It is instructive, after reading the opening speech of Sir H. Acland *in re* the punitive powers of the General Medical Council, to turn to the daily papers to see how well the Incorporated Law Society protects the interests of solicitors. Hardly a day passes without one finding that a prosecution of some unqualified legal practitioner has been undertaken by that body, or that some black sheep in the profession has been "struck off the rolls." As the case appears in the daily press, the public hears of it, and is instructed thereby. Contrast this with what happens at the General Medical Council: the proceedings are secret, and the result only appears in the medical press, and no further steps are taken to see that the man struck off the Register does not still practise. No prosecution for unqualified practising has been ever attempted by our ruling authority, and I do not suppose the general public knows of its existence. Our corporations or universities do not help us in the least to keep up the honour and dignity of our profession. Something ought to be done, or else men will soon ask, What is the advantage of being qualified at all? What with unqualified men, prescribing chemists, prescribing dentists, bone-setters, and the large race of spinsters, parsons, and others who do not hesitate to advise their friends to try their pet quack remedy, it is difficult to see the special advantages our expensive training has given us when a living has to be made for ourselves and those dependent upon us. It is a temptation to younger men to fling aside professional dignity when they find that fortunes are made by their unqualified opponents, who by their humbug and blatant advertisements attract the "custom" which the "gentleman" and the "educated" man loses because he has some love for the honour and dignity of his profession. We have a right to demand that we should be protected from this long-continued abuse, and that the public should be protected as well. If any further powers are needed by the General Medical Council—the General Meddling Council is a better name for it,—these powers can easily be obtained from Parliament. At present all we have to show for our registration fee is a single copy of the Register given (?) at registration. Other cases occur to me, but I must not take up more of your valuable space.

I am, Sir, yours truly,

Canonbury-place, May 19th, 1885. A. GEORGE BATEMAN.

"SUCCESSFUL ŒSOPHAGOTOMY FOR REMOVAL OF A HALFPENNY SWALLOWED THREE YEARS PREVIOUSLY."

To the Editor of THE LANCET.

SIR,—In your notice of the above case in THE LANCET of Saturday last you say that the child was treated for asthma, and that the swallowing of the halfpenny was lost sight of until this fact was elicited from the history of the patient given at the hospital a few weeks ago. As the little fellow was under my treatment for some months before he went, for the last time, to the Queen's Hospital, I beg leave to give the following short history of the case as far as it fell under my observation:—The child was first brought to me on Sept. 9th of last year, and at this time I learned from his mother that he had swallowed a halfpenny on Christmas Day, 1882. According to the mother's statement he was taken immediately to a surgeon, but as at the time the symptoms were not very urgent, no attempt was made to extract the coin. Subsequently he was taken twice to the Children's Hospital and once to the Queen's. According to the papers given to the mother he was treated at these institutions for bronchitis and asthma, and on the second occasion of her going to the Children's Hospital she was even ridiculed for supposing that the halfpenny had anything to do with the chest symptoms. When he came to me there was great difficulty both in breathing and swallowing, and much emaciation. Loud mucous râles were heard all over the chest, and there was impairment of resonance on the right side. I then gave it as my opinion that the halfpenny was impacted in the œsophagus, and by its pressure on the posterior wall of the trachea had led to the dyspnœa, and probably to some more serious change in the lung itself. The mother was unwilling at the time to take him again to the hospital, especially as I told her that in my opinion any attempt at removal would prove injurious, and perhaps fatal. In this I am glad to find that I was wrong, and that the skill of the surgeon has triumphed where the care of the physician was unavailing. I have only to add that while under my care he was treated with Parrish's syrup and cod-liver oil, and that for a time he improved greatly.

I am, Sir, yours obediently,

Birmingham, May, 1885. WILLIAM J. NOTLEY, M.D.

MANCHESTER.

(*From our own Correspondent.*)

VICTORIA UNIVERSITY.

AT the last meeting of the Court of the Victoria University, several matters of interest to the profession, and especially to medical students, came up for consideration. On the recommendation of the Council, it was resolved that candidates for the B.A. degree may, if not required to present both Latin and Greek in their intermediate or final examination, present in lieu of one of these languages, either French or German at their preliminary examination. The proposed interchange between the intermediate B.Sc. examination (Faculty of Science), and the preliminary examination in science (Faculty of Medicine), was postponed for future consideration. The following resolution, affecting especially old students of Owens College, was adopted, viz.: That anyone qualified before this year shall be admitted to the intermediate and final examinations for the degree of M.B. without having to pass the entrance examination in arts, or the preliminary examination in science, provided they have complied as students with all other requirements. This will enable many men who were students of the College before the granting of the charter to obtain a degree in medicine by passing examinations in professional subjects only. In the report presented to the Court allusion was made to the great loss the College and the University had sustained in the death of Dr. Watson, whose death, after a lingering illness, was chronicled in your pages recently. By his death the College loses both its professor of anatomy and its dean, Dr. Watson having been appointed to the latter office on the resignation of Dr. Gamgee last year. The latter has again, *pro tem.*, taken up the duties of dean. Rumour is already busy with several names for the vacant post of professor of anatomy, amongst them Dr. A. Young, who would be a formidable competitor against any candidate, he having for many years been senior demonstrator in the dissecting room prior to holding his present posts at the Infirmary and at the Salford Hospital.

THE CONSUMPTION HOSPITAL.

At the recent annual meeting of the subscribers to the Hospital for Consumption a very energetic report was submitted. This, the only hospital in the midst of so dense a population for the treatment of consumption and diseases of the chest and throat, has long laboured under many disadvantages. The accommodation has for some time past been inadequate to its needs, the numbers of patients increasing greatly every year, numbering for the year ending 1884 no less than 3032. The accommodation for the in-patients has been so defective that the Committee have taken a building at Bowdon, situate outside the smoke of the city, and have adapted it for the reception of sixteen patients, which accommodation is ultimately to be increased to sixty beds as soon as the necessary funds are raised, the amount now required being some £10,000. The out-patient department is also to be reorganised and the staff increased by the addition of another assistant physician. The income last year was £865, whilst the estimated expenditure for the coming one is estimated at £1500 at least, so that increased support will have to be found if the work of this charity is to be carried on efficiently.

CONFERENCE ON HEALTH AND EDUCATION.

The Conference on Health and Education lately held here may be looked upon as having been very successful, although at one time it appeared likely that the whole project would fall through. Under the presidency of Lord Aberdare the meetings were well attended, and many able papers were read by specialists on the various subjects submitted for discussion. Of course "over-pressure" came in for the lion's share of attention, and on the first day a paper was read by Mr. H. E. Oakeley, Her Majesty's inspector, in which he sought to prove that this mischief had been much exaggerated, whilst Mr. James Newbold, on behalf of the Manchester teachers, read a paper on the opposite side, asserting that over-pressure did exist to a large extent in elementary schools, and the latter view was apparently in favour with the majority of the audience. It was stated by one of the physicians to the Children's Hospital that during the past few years chorea had been more common amongst children of school age, and appeared to be often due to extra school work. Lord Aberdare, in summing up at the conclusion of the Conference, stated as his conviction that the charge of over-pressure existing to any large extent was not proven, and that under any system made for large numbers, if too rapidly followed, a small minority might be adversely affected.

THE SALFORD GUARDIANS AND THE MEDICAL SUPERINTENDENT.

The dispute which has for some time been going on between the Salford guardians and their medical superintendent at the Hope Hospital, and which culminated in the sending down an inspector from the Local Government Board to make inquiry respecting certain charges of neglect brought against the superintendent, has been settled in a satisfactory manner, the inspector reporting that in one or two minor points of discipline and refusal to answer certain questions put by the guardians the superintendent had erred, whilst the more grave charge of neglect was of such a character as could be settled by the guardians themselves, and did not call for the intervention of the Central Department. It is to be hoped that we have now heard the last of this unpleasant matter, which for some time has occupied attention here.

OUTBREAK OF SMALL-POX.

After some years of almost entire freedom from small-pox Manchester is at last suffering from an outbreak which at one time threatened to assume large proportions, as many as forty fresh cases having been reported in one week. Extra accommodation has had to be provided at the Monsall Hospital, and it has also been contemplated to use tents or marquees to meet the sudden emergency that has now arisen. To guard against the extension of the outbreak notices have been issued both by the Manchester and Salford health authorities urging revaccination.

THE CITY BOUNDARIES.

A Bill is now before Parliament for the extension of the city boundaries, by which several of the adjoining townships will be absorbed into the city. Practically they are as much part of Manchester as the city itself, and much of the ordinary municipal work is performed by Manchester—such as gas and water-supply, removal of infectious cases, &c.; and it is certain that in several of them the question of sewage disposal will shortly have to be grappled with, and this can be done by the corporation in a far more satisfactory manner than by the individual action of each local board. Notwithstanding this, one of the largest of these townships—viz., Newton Heath—has opposed the Bill, and will not, therefore, at present, be included within the city boundaries. It is in this township that a large number of cases of small-pox of the present outbreak is occurring.

NEW SOCIETIES.

The new Pathological Society has got well to work, and has had two very successful meetings. The proposed new Medical Society has not got further yet than the preliminary meeting, already noticed in your columns, and it is not unlikely that should the old society make some concessions as to the provision of a reading-room, &c., in a more central part of the city, further steps will for the present be postponed.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE COLLEGES SITE AT NEWCASTLE.

AT last this vexed question appears to have approached a settlement by the vote of the Town Council on Friday last, by which it was agreed to allow the Colleges of Medicine and of Physical Sciences sufficient land in an eligible position whereupon to erect suitable buildings adapted to the growing requirements of these institutions. The land had een granted at the price offered—namely, £10,000—by a ery large majority of the Council; so that this fact in itself ill have great weight with the Charity Commissioners, ose sanction is requisite to confirm the transfer. There however, some strong outside feeling still expressed st the sealing of the deeds.

NEWCASTLE INFIRMARY.

little time ago I told you that the weight of medical here was against the continuance of the infirmary in its present objectionable situation. The governors, while admitting this, thought that the erection of a new building was inopportune, but met the difficulty by what was called a temporary enlargement. Everything mundane may of course be considered temporary, but this new extension has a very substantial appearance (at least in bricks and mortar); so that I venture to say the removal of the infirmary from its present position is postponed for a generation at least, while the evils complained of will continue to be felt more and more. Dr. Coley of this city has appeared in the field since I last wrote as a candidate for the vacant post of physician at the infirmary.

SERIOUS ACCIDENT TO CHILDREN.

A very serious and unusual accident occurred on the 13th inst. at Seaham Harbour, Durham, by which seven children received injuries so severe that one has since died, and the lives of the others are in jeopardy. The South Hetton coal line is worked to the shipping station at the harbour in the manner usually adopted in the north—viz., by a wire rope running over sheaves. By some means the rope attached to the laden waggons got off the pulleys at a curved part of the line, and bore against a garden railing where some children were playing; the rope, being then pulled in a straight line, caught the children and threw them into a confused heap. Fortunately, the rope soon ceased running, or it would have sawn them in pieces; as it was, they were found bound down and helpless, requiring considerable force for their extrication. Drs. Gibbon, Beatty, and Dillon were soon able to render assistance. Some of the little ones received severe fractures and contusions; and one, since dead, had both legs fractured, with injury to the back. An inquest has been held, and it would appear from the evidence that some wear or defect in the sheaves was the cause of the rope slipping off.

MEASLES AT JARROW.

The very severe epidemic of measles at Jarrow has induced the medical officer of health to request the Town Council to pay the resident practitioners the customary fee of 2*s.* 6*d.* each case for notification, the health officers stating that it would be of immense advantage in stamping out the disease to know where the cases were. An economic councillor proposed "one shilling" as sufficient, but he could get no one to support him.

Newcastle-on-Tyne, May 19th.

EDINBURGH.

(*From our own Correspondent.*)

THE UNIVERSITIES (SCOTLAND) BILL.

THE General Council Associations of Edinburgh and Glasgow Universities are leaving no stone unturned which may in any way further the object which has brought them into existence. A joint meeting of the London members of the two Associations was held on Saturday at the house of Dr. Chalmers, at which several prominent graduates of both Universities were present. Sir J. Risdon Bennett presided. The meeting was called to adopt measures which may lead to the amendment of the Bill in consonance with the views of the Associations as already defined at their separate meetings. The following resolution, proposed by Dr. Crichton Browne, and seconded by Dr. Chalmers, was unanimously carried: "That this meeting of the London committees of the Associations of the General Councils of Edinburgh and Glasgow Universities is agreed that no Bill for the better administration of the Scottish Universities will be satisfactory which does not provide (1) for a largely increased representation of the graduates in the University Court; (2) for the transference of the management of the funds of the University from the Senatus to the Court; (3) for an extension, under proper restrictions, of the system of extramural teaching." The meeting also adopted a resolution suggesting the formation of kindred Associations in the Universities of Aberdeen and St. Andrews.

VOLUNTEER AMBULANCE ORGANISATION.

The movement inaugurated last winter by Surgeon-Major Evatt amongst the students of the Edinburgh School has prospered in spite of many difficulties, and a very efficient ambulance corps has been formed. Its equipments are as yet imperfect, and it has not yet received that Government recognition which was extended without hesitation to a similar corps recruited from the London hospitals; but, notwithstanding its present small resources and its lack of official encouragement, it bids fair to have a most prosperous career. When recent events necessitated the sudden calling out of a Volunteer regiment in Toronto, the men were accompanied to the front by a Volunteer ambulance corps and bearer companies, completely equipped and thoroughly disciplined; and this corps played a most useful part in the arduous campaign which General Midleton has just brought to a successful issue. Very few of the Volunteer regiments in the old country have any complete provision in this respect, and although on all hands such accompaniments are recognised as essential to the welfare of a regiment in war time, there seems to be a strange obliviousness to the fact that the proper time for their formation and development is in time of peace.

CONCERT AT THE ROYAL INFIRMARY.

A very successful amateur concert was given for the benefit of the patients of the Royal Infirmary on Saturday evening. The large operating theatre made a fairly convenient concert hall, and was well filled by patients and their friends. The audience seemed much pleased with the entertainment which had been provided for them, and warmly expressed their thanks to the performers at the close of the proceedings.

Edinburgh, May.

PARIS.

(From our Paris Correspondent.)

THE TREATMENT OF CHRONIC EMPYEMA BY ESTLANDER'S OPERATION.

CHARLES EDWARD CORMACK, son of the late Sir John Rose Cormack, has just taken his degree of Doctor of Medicine of the Faculty of Paris, the subject of his inaugural thesis being "Traitement de l'Empyème Chronique par l'Opération d'Estlander." The thesis is an octavo volume of 140 pages, in which is given a very good historical account of the various operative measures that have been employed from the time of Hippocrates to the present in the treatment of empyema, the operation known as Estlander's being, according to the author, the only curative treatment for this affection, particularly when accompanied by fistulæ, which, however, should be resorted to only when all other means have failed. The author gives a full description of Estlander's operation; and the work, which contains seven photographic plates, is interspersed with cases illustrative of the advantages of this method over all the others hitherto employed. The thesis winds up with the following conclusions:—1. Against the suppuration and fistula which follow purulent pleurisy, Estlander's operation is the only measure which responds to the indications of treatment of this affection. 2. It is indicated when all other means have failed. 3. One of the strongest contra-indications, and one of the causes of the failure of the operation, is the great extent of the suppurating cavity. 4. Tuberculosis, when not far advanced, is not a contra-indication of the operation; the evolution of tuberculosis may be slackened by early operative intervention. 5. The extent of the costal resection should be proportional to that of the cavity which it is proposed to fill. This resection should always be largely effected, the non-success of the operations hitherto performed being due to insufficient resection.

CAFFEINE AS A LOCAL ANÆSTHETIC.

Dr. Terrier, guided by the chemical analogy that exists between cocaine and caffeine, experimented with the latter on a dog, and obtained complete anæsthesia of the cornea. The next day, a workman presented himself at the hospital complaining of great pain in the eye caused by a foreign body in the cornea. Two drops of a 2·5 per cent. solution of the hydrochlorate of caffeine were instilled into the eye, which so completely anæsthetised the organ that the patient felt no pain whatever during the removal of the foreign body. From these two examples Dr. Terrier declared at a recent meeting of the Société de Chirurgie that he considered himself justified in concluding that the hydrochlorate of caffeine is as much an anæsthetic as the hydrochlorate of cocaine, and that the one may be substituted for the other in all cases where a local anæsthetic is required. This accords with the experience of Dr. Fauvel, the well-known laryngologist, who considers this possibilty of substitution an immense advantage in a pecuniary point of view, as the price of cocaine is still very high, being sold in this country at thirty francs per gramme, whereas the caffeine is sold at two francs for the same quantity. Dr. Fauvel employs the caffeine, to the almost entire exclusion of cocaine, in all pharyngo-laryngeal affections, in a 2 per cent. solution, a few drops of which are added to a little water, and the affected parts painted with the mixture, which affords almost instantaneous relief. The painting must of course be repeated several times during the day, in order to keep up the analgetic properties of the drug. Dr. Laborde, however, does not consider caffeine a proper substitute for cocaine, as he had tried some experiments with the former alkaloid as well as with theine, and could not obtain the least anæsthesia of the cornea, even with a concentrated solution. Prof. Panas observed lately in his practice that a solution of cocaine instilled into the eye dilated the pupil as much as atropine, which was contrary to what he had noticed before. In seeking the cause of this difference of action, Prof. Panas discovered that the cocaine he then employed was not like that he was in the habit of using. On further inquiry, he found that the substance in question was *the product* of the second maceration of coca leaves, and contained a large proportion of hygrine, which possesses mydriatic properties as marked as those of atropine, without the anæsthetic property of cocaine; hence the number of failures with some samples of the latter drug.

CRITICAL CONDITION OF VICTOR HUGO.

Victor Hugo is lying most dangerously ill from congestion of the lungs complicated with an affection of the heart. He has been ailing more or less for the last three or four months, and it was on Thursday last that he was seized with the attack under which he is now labouring. On that day, he gave a dinner to his friends in honour of M. de Lesseps, and appeared in good spirits. It was, however, observed that he was rather paler than usual. The reception was over by eleven o'clock, and in the course of the night Victor Hugo felt himself seriously indisposed. Dr. Emile Allix, the usual medical attendant of the illustrious poet, was immediately sent for, and he noticed that the movements of the heart were very slow and feeble. With the use of stimulants the patient seemed to revive, and during the following day nothing particular occurred to cause alarm, but in the evening his condition became aggravated, and early next day Professor Germain Sée was called in, who recognised symptoms of pulmonary congestion and heart disease. The patient who, from his advanced age, is evidently in a very serious condition, is yet in full possession of his mental faculties. He has a great aversion to medicine, and refuses to take it when offered to him. The bulletin of this morning, signed by Drs. Vulpian, Germain Sée, and Emile Allix, announces that though the prostration of the patient is very great, there yet seems to be a slight tendency to amelioration.

Paris, May 20th.

MEDICAL NOTES IN PARLIAMENT.

Lunacy Acts Amendment Bill.

ON the 19th inst. the House of Lords went into committee on this Bill, when a series of amendments, proposed by the Lord Chancellor, of which notice had been given and which occupied thirteen pages, were inserted, and the Bill was ordered to be printed.

The English Registration Bill.

During the consideration in committee of this Bill, Lord Balfour of Burleigh moved the rejection of the clause which provides that the receipt of parochial medical relief shall not disqualify a voter; and after some discussion, in which the Lord Chancellor, the Marquis of Salisbury, the Earl of Belmore, Lord Fitzgerald, the Duke of Richmond, and the Earl of Kimberley took part, the clause was struck out on a division by 72 against 47.

The House of Commons on the 20th inst., after a somewhat lengthy discussion, agreed to the Lords' amendment by 107 to 66 votes.

Irish District Lunatic Asylums.

On the 15th inst., in reply to Mr. Corbet—who asked the Irish Secretary whether it was true, as recorded in the last Parliamentary report, that 318 of the persons appointed as governors of district asylums never attended a board meeting during the year 1883; whether these persons consisted chiefly of noblemen, deputy lieutenants, and justices of the peace, and were appointed by the Lord-Lieutenant under statute; whether the duties devolving on governors included sanctioning the admission of patients, taking contracts, and general fiscal control; and whether some system could not be devised under which so large a number of the governors would not absent themselves from their duties—Mr. Campbell-Bannerman said that, assuming the figures to be correct, it must be borne in mind that these asylum boards are very large, and that the object of having them so large is to secure, not that all the members should always attend, but that there shall always be a quorum for the transaction of the necessary business. He was not aware of any complaints of failure in this respect, and it is always in the power of the Lord-Lieutenant to strengthen any board when that is deemed necessary.

Small-pox in Manchester.

In reply to a question by Mr. Leahy, relative to the removal of the 5th Dragoon Guards from Manchester to Newbridge, the Marquis of Hartington stated that the strictest orders have been given that no civilians shall be permitted to accompany the regiment to Ireland in any capacity whatever, unless they are medically examined and certified by the medical officer to be free from small-pox or the danger of conveying it to others.

Assistant Paymasters and Surgeons.

On the 21st inst. Mr. Borlase asked the Secretary to the Admiralty if it was a fact that the assistant paymaster in H.M.S. *Devastation*, who had nearly sixteen years' seniority in that rank, was thirty-seven years of age, and had been twenty years in Her Majesty's Service, was still junior in relative rank to the surgeon of that ship, who had been only fifteen months in the service, and was about twenty-three years of age; and, if so, if it was the intention of the Admiralty to allow so great an anomaly to continue. Sir T. Brassey said the figures given by the hon. member were approximately correct. The age of the surgeon on the *Devastation* was some three years more than stated in the question. No material change was contemplated with reference to relative rank of paymasters and surgeons. It was anticipated that the promotion of assistant paymasters would become more rapid in the future; but medical officers who could only enter the service on the completion of a long and expensive course of professional training would always be in a position to claim superior relative rank.

Obituary.

WILLIAM WATKINSON MOXHAY, M.R.C.S., L.S.A.

READING has just lost another prominent member of the profession by the death of Mr. Moxhay, which took place on Wednesday, the 20th inst., at the comparatively early age of sixty-three. He was educated at Guy's, and was formerly assistant accoucheur at St. Thomas's. His chest at this time was supposed to be somewhat delicate, and he went to sea in the Royal Navy for several years, which entirely invigorated him. He was then made house-surgeon at the Royal Berkshire Hospital, and was subsequently elected surgeon to the hospital, which position he held up to the time of his death. He was an expert operator and a thoroughly sound practitioner. His funeral took place on Saturday, just one month from the time of the funeral of his late colleague, Dr. Wells. Many thousand persons were present, all his colleagues, and most of the local medical men, as well as the governors, officials, and nurses of the hospital, among whom he was much beloved. He was a prominent Freemason, and the members of his lodge attended in large numbers at his funeral, as well as those of the lodge of Oddfellows to which he was surgeon.

SETH B. WATSON, M.D.

WE regret to announce the death of Dr. Watson, honorary physician to the Radcliffe Infirmary, Oxford, in his seventy-fifth year, which took place on the 15th instant. His horse having stumbled, he was thrown to the ground, and died immediately. Educated at St. John's College, Oxford, and afterwards at King's College, London, and St. George's Hospital, Dr. Watson early became physician to the Radcliffe Infirmary. Independent in thought, he from the first opposed the then universal practice of bleeding. Naturally diffident and retiring, he did not publish his opinions. Alone in his views at that time, he naturally met with much opposition, and it was even suggested that he ought to resign his appointment. He, however, lived to see his views generally accepted. Later in life Dr. Watson published a work on "The Cholera at Malta." In this he was indebted for much local information to his friend, Sir John Stoddart, formerly judge at that place. Later still he edited and published Coleridge's "Theory of Life," which met with a rapid sale. Coleridge lived with Mr. Gillman at Highgate, and after Mr. Gillman's death a manuscript was found which Dr. Watson at once identified as the work of Coleridge. It will shortly be republished, with other works of Coleridge, by Messrs. George Bell and Sons. An elegant and accomplished classical scholar, with refined and sensitive feelings, Dr. Watson will be long remembered by those who knew him best as a person of no ordinary intellectual power and a sincere friend.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following candidates passed the Primary Examination in Anatomy and Physiology for the diploma of Member of the College at a meeting of the Board of Examiners on the 11th inst.:—

ANATOMY AND PHYSIOLOGY.—G. Alexander Sutherland, Edward H. Ezard, Alexander Primroses, John McLachlan, F. Miller Johnson, F. Wyville Thomson, Charles W. Hayward, Robert Jardine, Edward W. W. Carlier, Percy Wardle, and Alfred Mann, Edinburgh; Sydney M. Whitaker, Walter Thompson, William Summerskill and George Handcock, Leeds; C. Louis Williams and Robert A. Beaver, Liverpool; Basil R. T. Trevelyan, Bristol; Edward C. Masser, Birmingham; Charles J. Whitley, Guy's; N. C. Ridley, St. Mary's.

ANATOMY ONLY.—Albert W. Gray, Birmingham; James B. Jamerson and Edgar N. Darwent, Edinburgh; Henry Hamilton, Bristol.

PHYSIOLOGY ONLY.—Richard F. Shepherd and Alfred Borradaile, Edinburgh; Benjamin P. Johnson, Edmund Copper and W. Courter Costine, Liverpool; Lock Macdona, Manchester and Liverpool; John Fullard, S. Vere Duncan, King's College.

(Candidates referred for three months, 3.)

Passed on the 12th inst.:—

ANATOMY AND PHYSIOLOGY.—Edward Molyneux, Liverpool; W. Aldren Turner, M. L. Trechmann, Arthur E. Barlow, J. Francis Haswell, Charles P. Kennard, Frank A. Juckes, Johnston H. Acheson, Ralph H. Maddox, F. R. B. Hinde, J. Hill Conyers, James Musgrave, H. Lloydd Roberts, J. C. Dunlop, Ernest C. S. Daniel, and W. Stacy Colman, Edinburgh; Charles P. Tanner and H. N. Cappe, University College; George A. Heberden, St. George's; H. T. Dudley Ryder, King's College; Adolph Bronner, Heidelberg; F. R. W. Brown, London; E. Marsh [illegible] St. Thomas's.

ANATOMY ONLY.—D. [illegible] lement Gomez, University College [illegible] J. E. Wright, King's College; E. [illegible] Walcot, Edinburgh; Sidney H. Badcock, St. Bartholomew's.

(Candidates referred for three months, 2; six months, 2.)

Passed on the 13th inst.:—

ANATOMY AND PHYSIOLOGY.—E. L. Cheatle, Francis H. Roberts, H. N. Baron, and Henry Smith, King's College; A. D. P. Hodges, London; Albert M. Sully, F. Barber Wells, Harold Dane, Charles T. Holland, Samuel Bullivant, and John E. Dyer, University College; James R. Anderson and E. L. Puddicombe, St. George's; Thomas Robinson and John Arthur Francis, St. Bartholomew's; W. L. Symes and W. H. Dolamore, St. Mary's; W. M. Helsham, St. Thomas's; A. G. W. Bowen, Guy's.

ANATOMY ONLY.—Henry J. Tizard, St. George's; Alfred W. Waller, St. Thomas's; Alfred R. Sieveking, St. Mary's.

PHYSIOLOGY ONLY.—A. H. Vassie, Edinburgh; C. H. Clayton, University College; H. A. Bray, King's College; C. Montague Leakey and Edmund D. Chalót, London.

(Candidates referred for three months, 4; six months, 5.)

Passed on the 14th inst.:—

ANATOMY AND PHYSIOLOGY.—Francis H. Cooke, H. Cleveland Smith, H. F. C. Marvin, and Richard L. Roberts, University College; Arnold Caddy, C. Mackinnon Clark, St. George's Hospital; J. A. Pope Lockett, London; Arthur J. De Butts, A. Stephen Hanson, and Robert W. Senior, King's College.

Anatomy only.—Walter Watkins, St. Bartholomew's; F. Maurice House, Pieter C. De Wet, and H. Bowman Shepperd, St. Thomas's; J. Percival Westrup, King's College.

Physiology only.—J. Valek Albert, St. George's; Philip J. Le Riche, University College; George H. Metcalf, Guy's; Frederick C. Auger, Charing-cross,

(Candidates referred for three months, 3; six months, 4.)

Passed on the 18th inst:—

Anatomy and Physiology.—Thomas F. Parry, Liverpool; Charles F. Marshall and G. E. Fryer, Manchester; G. Pirrie Boddie, Edinburgh; Ernest W. Evans, St. Bartholomew's; Reginald W. Bishop, C. Ramsden Salisbury, and J. V. B. Twamley, Leeds; J. Patrick Howe, Dublin; G. E. Roberts, University College; C. E. Matthews, Cambridge; J. Frederick Twist, Birmingham.

Anatomy only.—William C. Burt, R. Wynne Rouw, G. W. A. Mitchell, and F. Stanley Wood, Guy's; George S. Ridgley, E. A. T. Harris, and Edward Carnall, St. Bartholomew's; A. Piercefield Walters, University College; James Magauran, Dublin; Walter Mitchell, Sheffield; John W. Smith, Aberdeen; W. James Watkins, Bristol; Rhodes Hebblethwaite, Leeds; J. Edmund Syme, Edinburgh.

Physiology only.—Edwin Lambert, Leeds; Sidney E. Rossiter, St. Bartholomew's.

(Candidates referred for three months, 5; six months, 1.)

Passed on the 19th inst.:—

Anatomy and Physiology.—A. Evelyn O'Leary, Bristol; W. H. F. Noble and C. Alexander Ducket, University College; Alfred E. Nuttall, Alexander Harris, and Frederick O'Kinealy, St. Bartholomew's; Harry Corner and Digby F. B. Cotes, London; Harold A. Kidd, St. Mary's; Harford N. Edwards, Guy's; Sorabji M. Kaka, Bombay; H. Danvers, St. Thomas's; W. J. B. Carter, St. George's.

Anatomy only.—C. D. H. Rygate and E. E. P. Tindall, Guy's; Charles T. Bowen, St. Bartholomew's; J. T. R. Miller, St. Thomas's.

Physiology only.—H. F. Devis, Bristol; J. D. H. Smyth, St. Mary's; James Bamfylde, Guy's.

Passed on the 20th inst.:—

Anatomy and Physiology.—J. Milles Thorne, R. Grieve Hicks, Percy W. Streatfield, and James W. Smith, Guy's Hospital; William Halley and Reymond E. Fasnacht, Charing-cross; P. Tranto, Carpenter, St. Mary's; E. Ashcroft Tudman, University College; E. S. Farquharson, London.

Anatomy only.—C. R. H. Buckley, C. Glover Thorp, and John P. Pendlebury, Guy's; Frentz W. Guiselin, W. G. R. Farquharson, St. Mary's; W. H. Hand, St. George's; Frederic W. Barton, University College.

Physiology only.—Henry E. Belcher and H. H. Browne, University College; W. Fellowes Fisher and F. Stephen Reed, London; T. Hubbar Leggett and Ernest Loveday, St. Bartholomew's; Robert Stuart, St. George's; Frank Osborne, St. Thomas's; David T. Jones and Courtenay J. Fuller, Guy's; J. Ellison Finnie, Liverpool.

(Candidates referred for three months, 3; six months, 2.)

At the last Anatomical and Physiological Examination for the diploma of Membership of the College, 139 candidates presented themselves, 56 of whom, having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their studies for three and some to six months; 21 were referred in both Anatomy and Physiology, 14 in Anatomy only, and 21 in Physiology.

College Lectures.—The annual course of lectures will be resumed on Monday, June 1st., at 4 p.m., by Professor Edward Lund, F.R.C.S.E., who will deliver three lectures on "Some of the Injuries and Diseases of the Head and Neck, Genito-Urinary Organs, and Rectum." Professor John Wood, F.R.S., will deliver three lectures on "Hernia and its Radical Cure," commencing on Monday, June 8th. Mr. Edward Albert Schäfer, M.R.C.S., F.R.S., will deliver three lectures on "Secretion," commencing on Monday, June 15th. Professor Charles Stewart, M.R.C.S. (Erasmus Wilson Lecturer), will conclude the course by delivering three lectures on "Inflammation," commencing on Monday, June 22nd.

The Library of the College is closed to-day (Friday), and will also be closed on Friday the 29th inst., for the purposes of the Fellowship Examinations.

University of Cambridge.—The following have been examined and approved at Cambridge University for the degree of Bachelor of Surgery:—

Andrews, John's.
Haig, Trinity.
Lynch, Caius.
Nichol, Caius.

Royal University of Ireland. — The undermentioned have passed the examination for the degree of Master in Surgery:—

John Barron, W. J. Cowden, G. B. Crawford, M. H. Curtin, T. W. Dwyer, R. E. Foott, W. R. Hawkins, J. McAleer, Michael McCarthy, W. B. R. McWha, G. F. H. Marks, John Meenan, John Moore, James Musgrave, James P. O'Byrne, Robert Petticrew, E. L. Pooler, John Ryan, William Sexton, Norman Smyth, Robert Thomson, F. J. Tresilian, J. J. Walsh, M. J. Whitty.

The following have obtained the degree of Master in Obstetrics:—

Maurice Connery, Alexander Corry, M. H. Hannigan, Daniel Hennessy, Michael McCarthy, Morgan McSwiney, W. B. McWha, Robert Petticrew, John Ryan, William Sexton, F. J. Tresilian.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 7th *inst.*:—

Tyndall, Francis, M.R.C.S., Liverpool School of Medicine.

Passed on the 14th:—

Dearden, Wm. Francis, M.R.C.S., Manchester School of Medicine.
Creighton, Edward, St. Thomas's Hospital.
Dobson, Leonard Charles Talbot, St. Bartholomew's Hospital.
Hall, Thomas Godfrey, Leeds School of Medicine.

The Princess of Wales has consented to act as President of the Ladies' Sanitary Association in Dublin.

The annual dinner in connexion with the Pharmaceutical Society of Great Britain was held on the 19th inst.

On Wednesday night an outbreak of fire took place in St. Mary's Hospital, Cambridge-place, but was speedily extinguished.

German Hospital.—The Queen has presented this Hospital with a donation of £100 as an addition to the collection made at the anniversary festival held on the 6th inst.

At the sixth general meeting this session of the Hospitals Association on the 20th inst., Miss Louisa Twining read a paper entitled "Thoughts on the Diet of Nurses in Hospitals and Infirmaries."

At the adjourned inquest on the 15th inst. touching the death of Dr. Charles Alworthy, of Toft Hill, near Darlington, which occurred on the 23rd ult., the jury returned a verdict of death from natural causes.

Charing-cross Hospital.—The Duke of Edinburgh presided on Wednesday at the triennial festival, held at Willis's Rooms, in aid of the funds of this hospital, when subscriptions to the amount of nearly £7000 were announced as the result of the meeting.

On the 16th inst. the Archbishop of Canterbury opened the new infirmary of the Croydon Union. The designs are for six pavilions, with 643 beds; but up to the present only four pavilions, with 435 beds, have been erected. The cost of the building is £101,000.

The Levée.—At the Levée held by the Prince of Wales on behalf of the Queen at St. James's Palace on the 11th inst., Surgeon E. West Symes, M.D., of the 2nd West York (Prince of Wales's Own) Yeomanry Cavalry, was presented by Lieutenant-Colonel Edwards.

Glasgow Water-supply.—A Bill has passed a committee of the House of Lords giving power to raise the level of Loch Katrine and Loch Arklet, with a view of providing additional and improved water-supply to the Glasgow district, at a cost of over a million sterling.

On Wednesday last, in the presence of a goodly company of ladies and gentlemen, Sir Spencer Wells unveiled a medallion of the late Mr. Peter Squire in the Examiners' room of the Pharmaceutical Society, Bloomsbury-square, of which Society Mr. Squire was one of the founders.

University of Brussels.—At the May examinations for the degree of M.D., eleven English candidates presented themselves, of whom the following five were successful:—William Budd, Herbert Fenton (distinction in Anatomy), Herbert Spencer (distinction in Medicine and Surgery), G. Walter Steeves, and Charles R. Walker.

A conference was held at Canterbury on the 15th inst. between the various sanitary authorities of the district, to consider the best means to be adopted for dealing with an outbreak of cholera or other epidemic disease during the approaching summer. There being no infectious hospital in the district, it was resolved that hospital tents should be hired, and immediately on a case of disease being reported, isolation should be resorted to.

Judge Abdy on Medical Charges.—In an action brought by a medical man in the Colchester County Court the plaintiff's counsel said the amount claimed was £20 2*s*. Defendant had paid £8 8*s*. into court since the bill was delivered. The account began in 1879, and extended until 1882. The counsel for the defence said his client felt that he was being very harshly used by the plaintiff in consequence of the manner in which the action had been brought. A number of very unnecessary visits had been paid. His honour (Judge Abdy) said he was astonished at the moderation of the charges made by country medical ractitioners. He did not know any body of men who orked harder. The jury found for the plaintiff for the full mount claimed.

St. Bartholomew's Hospital, Rochester.—The hole of the brickwork on the north side of the hospital is ow in course of repair, and stone windowsills are to be rovided. The general sanitary condition of the building as been engaging the attention of the Board of Trustees for ame time past; and it has now been decided to carry out ome work in connexion with the present sanitary arrangenents at considerable cost.

King's College Hospital.—The festival dinner in onnexion with this institution was held on the 16th inst., he Duke of Cambridge, President of the hospital, in the hair. The number of in-patients received during 1884 was 193, and of out-patients treated 15,103. The deficit in 831 amounted to £8689; in 1882 it was reduced to £2576; n 1883 it was £2889; and last year it again rose to the arge sum of £6668. During the evening subscriptions and onations amounting to £2229 were announced.

Training School and Home for Nurses.—An xamination, written and *vivâ voce*, was held at the St. Iarylebone New Infirmary, Notting-hill, on the 13th inst. Lectures and chemical teaching had been given by Mr. John R. Lunn, medical superintendent, Mr. Larder, assistant medical officer, and Mr. Clifford, dispenser, on Chemistry and Hygeia, and by Miss Wyld, lady superintendent of the Nurses' Home. The School for the Training of Nurses for the Sick Poor was opened on the 22nd of July, 1884, and is in connexion with the "Nightingale Fund."

Fifeshire Medical Association. — The spring meeting of this Association was held at Dunfermline on the 1st inst. Dr. Dow, the president, read a paper on the Management of Habitual Drunkards, and Dr. Naysmith one on Practical Sanitation. Dr. Brakenridge exhibited a case of Elephantiasis Græcorum. A proposal by Dr. Moir to have a course of health lectures given in the principal towns in Fifeshire was heartily adopted. An able paper was also read by Dr. Turnbull in favour of the Scottish legal system of sending lunatics to asylums.

At the third international conference of the Societies of the Red Cross, held last year in Geneva, the Empress of Germany offered 5000 francs and a gold medal as a prize for the best model of a soldiers' barrack and field hospital. The barrack must be large enough to contain twelve beds, easy of transportation, made with interchangeable parts, and capable of being taken down and reconstructed. The designs are to be sent to Antwerp by September 1st, 1885, when a committee will decide on their respective merits.

The Hunterian Museum.—A special meeting of the trustees of the Hunterian Collection was held at the Royal College of Surgeons on the 15th inst. to elect four trustees in the vacancies occasioned by the decease of Dr. Allen Thomson, of the Duke of Buccleuch, and Mr. Cæsar H. Hawkins, and by the resignation of Mr. William Hunter Baillie, when the following gentlemen were respectively elected to fill such vacancies:— Professor H. H. Flower, LL.D., F.R.S., the late Conservator of the Museum; Lord Wolsingham; Sir James Paget, Bart., LL.D., F.R.S., late President of the College; and Mr. Wm. Hunter Baillie, jun.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

Barst, C. T. U., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer of Health to the Willington-on-Tyne District, vice C. W. C. Fletcher, M.R.C.S., L.R.C.P., resigned.

Childe, C. P., M.R.C.S., has been appointed Assistant House-Accoucheur to King's College Hospital.

Crabb, James, M.D., C.M.Ed., has been appointed Medical Officer for the Upper Holloway West District of the Islington Union, vice Cowen.

Davies, Howard, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse, Pontypridd Union, vice Hopkins, deceased.

East, C. H., L.S.A.Lond., has been appointed Physician's Assistant to King's College Hospital.

Easton, Thomas, M.A., M.B.Ed., has been appointed Medical Officer to the Wigtownshire Combination Poorhouse; and Medical Officer to the Parochial Board of Kirkcolm, and to the Corsewall Lighthouse.

Gray, J. P., M.R.C.S., L.S.A.Lond., has been appointed Ophthalmic Clinical Assistant to King's College Hospital.

Griffin, James, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Cropredy District of the Banbury Union, vice Thompson, resigned.

Harries, J. F., M.R.C.S., has been appointed House-Surgeon to King's College Hospital.

Hughes, E. A., M.R.C.S., L.R.C.P., has been appointed Physician-Accoucheur's Assistant to King's College Hospital.

Jeffree, F., M.R.C.S., has been appointed House-Surgeon to King's College Hospital.

Jenkins, Jenkin, L.F.P.S.Glas., has been appointed Medical Officer for the Pontypridd District of the Pontypridd Union, vice Hopkins, deceased.

Kealy, Joseph Patrick, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Gulgong Hospital, New South Wales.

Kilham, Charles Speight, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Assistant Medical Officer to the Workhouse, Sheffield Union.

Lewis, P. G., L.S.A.Lond., has been appointed Assistant House-Physician to King's College Hospital.

McDougall, Aymer Robert, M.B., C.M.Ed., M.R.C.S., has been appointed Honorary Surgeon to the Chesterfield and North Derbyshire Hospital, vice Foulds, deceased.

Paddison, Edmund Howard, M.D.Lond., M.R.C.S., has been appointed Assistant Medical Officer to the City of London Lunatic Asylum, Stone, vice Mercier, resigned.

Priestley, R. C., M.R.C.S., has been appointed House-Surgeon to King's College Hospital.

Sellick, J. Henderson, M.R.C.S., has been appointed House-Surgeon to the North-West London Hospital, Kentish-town-road.

Sutherland, John R., L.R.C.S.Ed., has been appointed Medical Officer for the Rainton District of the Houghton-le-Spring Union, vice Jackson.

Vachell, Herbert Redwood, M.D., M.R.C.S., L.S.A.Lond., has been appointed Out-patient Medical Officer to the Glamorganshire and Monmouthshire Infirmary, Cardiff, vice Thomas Wallace, M.D., appointed Surgeon.

Violette, William Bradley, M.B., C.M.Glas., has been appointed Government Medical Officer and Vaccinator for the District of the Lower Richmond River, New South Wales.

Births, Marriages, and Deaths.

BIRTHS.

Bothamley.—On the 13th inst., at Cadogan-terrace, Victoria-park, the wife of W. P. Bothamley, M.R.C.S., of a son.

Drew.—On the 20th inst., at Saville House, Buntingford, Hertfordshire, the wife of J. Bowerman Drew, F.R.C.P.S. & L.M., of a daughter.

Flint.—On the 14th inst., at Westgate Lodge, Westgate-on-Sea, the wife of Arthur Flint, M.D., of a daughter.

Holthouse.—On the 15th inst., at Reigate, the wife of Edwin Hermus Holthouse, F.R.C.S., of a son.

Joynt.—On the 25th ult., at Hanover-street, Kingston, Jamaica, the wife of Surgeon-Major H. W. Joynt, Army Medical Staff, of a daughter.

MARRIAGE.

Foley—Tweddle.—On the 14th inst., at St. Leonards, Streatham, Charles N. Foley, M.R.C.S., to Mary Elizabeth (May) Tweddle, daughter of the late Edward Tweddle, of Norwood, S.E.

DEATHS.

Allen.—On the 15th inst., at Ardleigh Lodge, Romford, very suddenly, William Edward Allen, F.R.C.S., Brigade-Surgeon, Bengal Army (retired), aged 50.

Barnes.—On the 13th inst., at 6, Portland-square, Carlisle, Dorothy, younger daughter of Henry Barnes, M.D., F.R.S.E., aged 1 year and 4 months.

Colebrooke.—On the 19th inst., at Brightlands, Southborough, Tunbridge Wells, Henry Colebrooke, M.D., aged 70.

Cree.—On the 18th inst., on board the steamship *Dorunda*, on his way home from Queensland, Percy Kinburn Cree, M.R.C.S. & L.S.A.Lond., Surgeon R.N., aged 29.

Graves.—On the 14th inst., at Canning-place, Kensington-gate, John Stewart Graves, Deputy Inspector-General of Army Hospitals, late Surgeon of the 4th Light Dragoons, and for many years Surgeon at the Tower of London.

Lee.—On the 12th inst., at Ashbourne, Derbyshire, John Lee, M.D., aged 81.

Moxhay.—On the 13th inst., at his residence, London-street, Reading, William Watkinson Moxhay, M.R.C.S., aged 63.

Oldman.—On the 16th inst., at Huntingdon, John Oldman, M.R.C.S., L.S.A.Lond., Surgeon-Major, 5th Battalion King's Royal Rifle Corps, the second son of the late Thomas Oldman, Esq., of Gainsborough, Lincolnshire, aged 48.

Packman.—On the 11th inst., at Anerley, John Daniel Vittoria Packman, late Surgeon, H.E.I.C.S., aged 71.

Priest.—On the 13th inst., at Waltham Abbey, Essex, Arthur Priest, M.R.C.S., L.R.C.P.Ed., aged 68.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

Monday, May 25.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

Tuesday, May 26.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8 P.M. Dr. Spencer *Cobbold: Cases of Hæmaturia due to Bilharzia (Illustrated by* Specimens).—Dr. Angel Money: The Experimental Production of Chorea and other Results of Capillary Embolism.

Wednesday, May 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—*Operations, 2 P.M.; Saturday, 2 P.M.* Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens as usual. Discussion on Dr. More Madden's paper on Fibro-myomata.

Thursday, May 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. C. Meymott Tidy: Poisons.

Friday, May 29.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—9 P.M. Mr. J. J. Coleman and Professor J. G. McKendrick: Mechanical Production of Cold, and Effects of Cold on Microphytes.

Saturday, May 30.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Rev. C. Taylor: "The Teaching of the Twelve Apostles," an Ancient Document, with Illustrations from the Talmud.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"DRINKING PARAFFIN OIL."

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 9th a case under the above heading is recorded by Mr. Willson. In January last I had to deal with a case where paraffin oil was accidentally swallowed, of which the following is a brief account.

J. H——, aged forty-three, stableman, took with him as usual to his work a tin flask containing tea. There was a similar flask in the stable, which contained about half a pint of paraffin oil. The two flasks having been carelessly placed near each other, he, feeling thirsty, picked up the wrong one, and swallowed nearly the whole of its contents. I saw him in the surgery about an hour afterwards; he was pale, and his face wore an anxious expression, more the result of mental distress than of actual suffering. There was a strong odour of paraffin oil in his breath. He complained of his throat feeling hot and dry, and of a sensation of warmth in the epigastrium, but there was neither pain nor tenderness on pressure. There was no nausea. The pupils were normal. The pulse was full and rapid, chiefly, I think, the result of excitement. An emetic of twenty grains of sulphate of zinc was given, and the vomiting encouraged by copious draughts of warm water. By these means the stomach was thoroughly emptied. The vomited matters consisted of water, a small quantity of viscid mucus, a little partially digested food, and about eight ounces of paraffin oil. For after-treatment I ordered demulcent drinks and a dose of castor oil. He went to work next morning, feeling none the worse for his experience of the day before, not even the slightest indication of gastric irritation having shown itself, although the paraffin oil must have been in contact with the mucous membrane of the stomach for at least an hour. There was very little food in the vomited matter, so that the mucous coat had not the protection from irritation which the abundant presence of food would have afforded.

I am, Sir, yours faithfully,

T. C. M'CULLOCH.

Hanwell, May 11th, 1885.

Mr. U. M. Snyder.—1. Analogous cases are often met with, but are not easy to explain.—2. Bichat's work, of which the first edition was published in 1805, was translated into English by F. Gold, M.R.C.S.; but it has long been out of print. An American edition of this translation was published in Boston (Richardson and Lord) in 1827 (*vide* Index Catalogue of the Surgeon-General's Library, Washington).

W. D. D. Parks, B.A., L.K.Q.C.P.—Our correspondent's letter is written with almost invisible ink and on very thin paper; but, so far as we can make it out, we agree with him in very lightly esteeming the American degree of which he speaks.

Mr. J. Morth is referred to a general notice at the head of this column.

DR. TIBBITS' MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to acknowledge through THE LANCET, with many thanks, the *following contributions* received towards the fund being raised for the widow and nine children of the late Dr. E. T. Tibbits, Physician to the Bradford Infirmary, whose life was so suddenly brought to its close by an attack of acute pneumonia on April 11th last:—

Dr. Frederick Orton ...	£10	0	0	Dr. Saul	£2	2	0
Dr. G. Oliver	5	5	0	Saml. Knaggs, Esq. ...	2	2	0
W. E. Rawstorne, Esq....	5	0	0	H. E. Taylor, Esq. ...	1	1	0
Francis Vacher, Esq. ...	5	0	0	A. Locker, Esq.	1	1	0
Mr. and Mrs. Vertue Edwards...	2	2	0	Dr. H. M. Tuckwell ...	1	1	0
				Dr. Wakley	2	2	0

Further contributions will be thankfully received by me, or by Mr. W. Maw, Secretary to the Bradford Infirmary.

I am, Sir, yours faithfully,

JOHN APPLEYARD, F.R.C.S., M.B.Lond.

1, Clifton-villas, Manningham, Bradford, Yorks, May 19th, 1885.

ORTHO-PHENOSULPHONIC ACID.

'. VIGIER, in a French pharmaceutical journal, states that of the three phenosulphonic acids the ortho-acid only has antiseptic and disinfecting properties in a marked degree. It is not so poisonous as phenol, as much as ten grammes having been taken in small doses in twenty-four hours without inconvenience. The subcutaneous injection of 2·8 grammes proved fatal to a dog. It appears to be a powerful antiseptic, although it is exceeded in this respect by its sodium salt.

Mr. E. A. Rodway.—The number is probably very small; but we have not the information at hand.

Microscope is perhaps a little hypercritical. Men are but children of a larger growth, and seem to like pictures. This is a pictorial age.

Mr. Walter Spencer will find a full description of the examinations for the degree in THE LANCET of April 18th last.

Mr. R. Thackray.—We cannot promise without seeing the paper.

A CASE OF INTUSSUSCEPTION.

To the Editor of THE LANCET.

SIR,—Cases of this kind are sufficiently rare to be worth recording, and the following may prove interesting enough to find a place in your columns.

On May 11th last a young married woman brought her baby, a girl aged six months, into my surgery at 6 P.M., saying that "she could not make the child out," as she had been constantly crying for two hours just after giving a sudden scream, and before this she was perfectly well. The child seemed pinched about the face, and was very restless; there was no feverishness or elevation of temperature, and I could not then decide what was the matter. I ordered her a little soothing medicine, and requested to know later on how she was. At 10 P.M. I was sent for, as the child seemed worse. On my arrival I was told that she had passed on two occasions a quantity of blood, which the mother showed me on her lap. I at once suspected that I had to deal with a case of intussusception, and ordered the child to have an enema, and prescribed two-drop doses of opium and five-drop doses of tincture of belladonna every two hours, with hot fomentations to the abdomen.—12th: The child was seen three times; she had passed a restless night, with fits of pain and straining, and vomiting of rather clear fluid; had not taken the breast. The enema had had no effect. There was now to be felt a decided hardness in the left iliac fossa, and the abdomen was somewhat swollen; no urine had been passed. The medicine had for the most part kept down. The enema was repeated twice. I passed my little finger up the rectum, but could detect nothing; this part of the bowel seemed quite free. Hot poultices were applied all day.—13th: The child was decidedly worse in every respect, and in the evening I managed to borrow after some difficulty a pair of bellows, and attaching to them a piece of indiarubber gas tubing, and to this the elastic nozzle of an enema syringe, I pumped up for about twenty seconds a quantity of air, and then left for the night, with orders to continue the medicine, and to wet the lips with milk and a little brandy.—14th: There was no relief to the child, and she seemed to be getting worse; so in the afternoon I had the bellows used again more vigorously and for a longer time, the nurse using them while I held the tube in the rectum. On my last visit at night there had been no relief, except that the child had passed some urine; but it seemed to me that the abdomen was slightly softer. I could, however, give but slight hopes of recovery.—15th: The father at an early hour left a note at my house, asking me to visit the child soon, as he thought there was a change for the better. On my arrival I found that an hour or two after I had left on the previous evening the bowels had been freely open, and again about five o'clock in the morning, and that the child had had a refreshing sleep, and had taken the breast freely. The abdomen was quite soft, with very little pain, and the child looked comparatively bright. I thought it best to continue the medicine, but at longer intervals.—16th: There was great improvement in all ways, the child feeding freely without sickness. The bowels not having acted, I ordered a small teaspoonful of syrup of senna to be given in the evening. This, however, was not required, as on my visit next morning (May 17th) I learned that the bowels had acted naturally twice, and found the little one being dressed, and laughing and screaming at its father, perfectly recovered.

I am, Sir, yours very truly,

Queen's-park, Harrow-road, May 18th, 1885. A. L. GRIFFITH.

Mr. Thos. Cantrell.—Our space is too fully occupied at present to allow us to entertain the proposition.

W. J. N.—A copy of the work is to be sent to every registered medical practitioner.

CEREBRAL SURGERY.

To the Editor of THE LANCET.

SIR,—At the discussion at the Medical and Chirurgical Society last week it was stated that one of the difficulties to be contended against in operations on the brain was the [illegible] this I would suggest pressure [illegible] orrhage. For sponge grafting. Three times I [illegible] as is used in [illegible], for stopping hæmorrhage from cerebral sinuses, and once for bleeding from brain tissue; in each case it acted most satisfactorily. After some hours the sponge may be removed, or it may be gradually clipped off with a pair of scissors until only a very thin layer remains.

I am, Sir, very truly yours,

Birmingham, May 20th, 1885. GILBERT BARLING, F.R.C.S.

MR. BARNARDO'S HOMES.

THERE are now twenty-six different institutions under the direction of Mr. Barnardo, F.R.C.S.Ed. Of these, the Ragged Schools were founded in 1866; the Boys' Home, Stepney, in 1869; the Children's Hospital in 1872; the Girls' Village Home in 1873; the Little Boys' Home, Jersey, in 1880, and the other branches subsequently. From 1866 to the present year 1829 boys and girls have actually been received. There are 602 girls and 754 boys still in the institutions, while 2490 other children have received education, in whole or part, during 1884. Thus, a total of 4319 children were benefited during the year. Three hundred and fifty children have emigrated during the year, 320 boys and girls going to Canada, 9 girls to South Africa, and 21 boys and girls to Australia. The donations for all purposes during the year amounted to £60,423, which is the highest amount ever reached, and an increase over the previous year of £4700. The disbursements exceeded the income so much that the bankers' account was actually overdrawn by £5469. An exceedingly useful work is being accomplished by Mr. Barnardo, and it is to be hoped that the support accorded to him in the future will enable him to materially extend his field of labour.

M. C. C.—Try forcible pressure on the ganglion by means of the thumbs. Subcutaneous incision of the wall of the ganglion is another method.

SMALL-POX AND CHICKEN-POX.

To the Editor of THE LANCET.

SIR,—I have seen recently several cases of chicken-pox in adults which have been sent to small-pox hospitals, probably partly owing to the disease not being looked for at this period of life. In distinguishing cases of chicken-pox from small-pox I have chiefly relied on three points:—1. The nature and duration of the general symptoms, which seem sometimes to begin with the eruption in chicken-pox, at other times to go on after the eruption has come fully out. They are also mild. 2. The rapidity with which the eruption has become vesicular. An aborting small-pox eruption may be distinguished from a scabbing chicken-pox eruption by its not showing evidence of previous vesication, unless it has absorbed at a pretty advanced stage, when the differentiation of the diseases is aided by other circumstances. 3. The distribution of the eruption. This in small-pox generally conforms to the rule of being most abundant on the face and head, next on the limbs, preferably the arms, and least on the trunk. Chicken-pox is less regular, but usually most spots are found on the back. I would suggest that medical practitioners not familiar with the two diseases should occasionally refresh their recollection of the symptoms, &c., by looking over Dr. Collie's articles in Quain's Dictionary of Medicine, which from their practical nature will, I am sure, benefit others as they have done myself.

I am, Sir, your obedient servant,

JAMES A. PHILIP.

Metropolitan Asylums Board River Ambulance Service, May 19th, 1885.

Z.—Of course, each case of illness has to be studied separately, and idiosyncrasy has to be kept in view.

MR. DANIEL MURRAY O'HARA.

To the Editor of THE LANCET.

SIR,—It would be invidious on the part of Mr. Daniel Murray O'Hara to endeavour to disprove the remarks in the paragraph in your columns of the 16th inst. It was my intention to have invited the attention of that gentleman to the reports circulated in the Liverpool papers concerning him, and to have called his attention to the fact that I had already communicated to the Branch Medical Council in Ireland some months ago the imposition that was being then practised on his, I venture to hope, unsullied name. Seeing, however, that you have unfortunately fallen into the error, I hasten to assure you that I thoroughly sifted the circumstances on the occasion to which I have referred. I think you will find that the person who has committed suicide is Owen Patrick O'Hare, who had been sentenced to penal servitude for some offence some years ago, and scratched off the Register in consequence. This man assumed the name of O'Hara, being very similar to his own, and, unfortunately for him, has been the victim of self-sacrifice. If Mr. Daniel Murray O'Hara, with whom I am unacquainted, has been relieved of a weight on his mind, so much the better, from whom no thanks are needed by

Your obedient servant,

May 18th, 1885. AN OLD CORRESPONDENT.

P.S.—I enclose my card.

Dr. Randurtz (Berlin).—The London Institution is the only one of the kind of which we have knowledge.

USE OF THE TRICYCLE IN PREGNANCY.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "A Member of the Cyclists' Touring Club," I would record my opinion that a pregnant woman may, with ordinary precautions, ride a tricycle to full term. Hitherto I have found it difficult to persuade them to take the exercise after the seventh month; but from feelings of delicacy only, not from inability.

I am, Sir, yours faithfully,

Leeds, May 18th, 1885. JNO. GEO. NEVITT.

enables me to show you her portrait and you to realise better the verbal description. I need only describe to you the history of the onset of this extremely interesting case and the distribution of the lesions; individually the lesions are the same in character as those we have already described, but the association of patches supervening on the diffuse disease is very interesting, and also the unilateral character of that condition. The concurrence of ordinary keloid is paralleled in a slight degree by the case of Mrs. L——. Now, I want you particularly to observe that we have two stages *in the development of this case: the first marking the* onset of the diffuse acute, the second of the chronic circumscribed, form. In the onset of the diffuse part of it we observe it was very sudden, without apparent cause and preceded by œdema. So far these features are not very exceptional, and we have seen them all illustrated in our last lecture,[2] but its distribution was hemiplegic, and did not involve the upper extremity, nor the face at that time, but only the left side of the trunk and the whole of the left leg. The very opposite of what usually occurs, the distribution being usually paraplegic, but involving the upper half of the body. The distribution in this case is that of a spinal hemiplegia in the upper dorsal region. Some time later the second stage set in. The history does not enable us to infer the exact period, although we know that it was within a year, but we only learn the distribution of the new phase three years after the onset of the disease when she came under Dr. Addison's care. This was the stage of the development of patches. They came on slowly as far as can be gathered, and with the exception of those on the face were to a great extent right-sided, no special distribution in a recognisable nerve area was to be made out, but the patches on the left side of the face point to the influence of the fifth nerve, which is a not uncommon distribution for morphœa, as we have already seen. So far as the patches are concerned, there is nothing very unusual either in their development, physical characters, or distribution; it is their association with the diffuse form which is the chief point of interest, and this is rendered still stronger by the following two cases, where the patches preceded the diffuse condition and in one spread from the patch till it involved a larger tract. The first of the two is Mr. Gaskoin's case, to which I have before alluded as remarkable in so many ways that it deserves to be recalled at least in a brief abstract. The patient was a woman aged thirty-five, and the onset of the disease was described with confidence by the patient to a mental shock during pregnancy, and there was no history of rheumatism, gout, or syphilis. The disease was first noticed in the form of two patches on the outer and upper part of the right thigh; the patches increased in number, amounting to about thirty, and were situated more on the anterior than on the posterior surface of the body, rather more on the right side than on the left, and not in corresponding situations, and more on the lower than on the upper limbs. They were depressed in the centre, pigmented in various tints, brown, red, purple, yellow, and yellowish-white, were to some extent anæsthetic, though some were painful and tender, and attended with excessive pruritus. About three years later, after going to the seaside in inclement weather, she returned with "pasty œdema" of the legs and trunk, and the colour returned to the skin very slowly after pressure. The œdema gradually disappeared in the course of the ensuing six months, and simultaneously the skin became sclerosed, spreading from the morphœa patches, which became diffused over a large surface, losing their concavity and defined outline. The patient emaciated, losing two stones in weight, and gradually the whole skin, except the head, became involved, and the patchy was converted into a diffused atrophic scleroderma. At a later period the face was also affected below the forehead, but not the buccal mucous membrane. For the many and other interesting details I must refer you to Mr. Gaskoin's description in the sixtieth volume of the Medical and Chirurgical Transactions.

Here is another somewhat similar case, related by Dr. Dyce Duckworth. A servant, aged sixteen, had some patches of morphœa on the left thigh; seven years later she had an attack of acute rheumatism, and the patches spread and got harder; six months later the left foot and leg got hard and stiff, followed by the right foot and leg, and both forearms and hands, which were sclerodactylous. The disease was symmetrical on the arms and below the knees; there was none above the edge of the patella on the right leg, but there was a streaky band of induration on the left leg, which connected the diffuse part of the disease with the enlarged original patches on the inner and back part of the thigh. In Mr. Gaskoin's case you observe again, after exposure to cold, induration spread from the patches and became general. This is distinctly stated, and is in opposition to the view Mr. Hutchinson takes that morphœa never spreads, but only increases in size by fresh patches forming near and coalescing. Dr. Duckworth also states that after an attack of acute rheumatism the patches spread and got harder, and later diffuse scleroderma developed symmetrically on the extremities.

These three cases, then, show us that the morphœa condition may precede or follow the diffuse form, which in this class of case is always in the shrunken condition; and it appears to me that patchy scleroderma is almost as nearly related to diffuse scleroderma as patchy eczema is to general eczema. But I would have you to understand that while I regard them both as the outcome of the same pathological process, and occurring probably in individuals of the same constitution, the exciting cause of the two forms may be very different in its nature. The pathology, diagnosis, and treatment are the same in this as in the other forms of scleroderma.

---

[2] As the case has been repeatedly described and commented on, the relation of the case is omitted.

CLINICAL STUDY OF THE LIVER VIEWED THROUGH THE URINE.

BY GEORGE OLIVER, M.D.LOND.

(Continued from page 884.)

No. II.—THE PHYSIOLOGICAL AND CLINICAL ASPECTS OF THE BILE SALTS IN THE URINE.

IN *hæmoglobinuria* the blood-corpuscles undergo rapid and wholesale solution, and the liberated hæmoglobin dialyses into the urine. Since I began to use the peptone test I have only examined the urine of one case of this interesting ailment—interesting specially from the pathological relationship which it suggests between a suddenly induced hepatic or portal disorder, flooding the blood with the central component of the bile, and the rapid hæmolysis. I am indebted to Dr. Tyson of Sheffield for sending me the sample to which I refer, and which enables me to demonstrate what I, and probably others, have long suspected—namely, the presence of a large quantity of bile salts in the urine of hæmoglobinuria. This is the specimen, a good example of the urine provided by this curious disease. The quantity at my disposal being very small, I dilute it to the specific gravity of 1008, and I obtain a deep blood-coloured solution. On dropping a citric acid test-paper into sixty minims of this diluted urine, a dense zone of precipitated proteid soon forms across the middle of the column, the portion of the urine below it remaining quite clear. Those of you who were present when I read my former paper will call to mind that I pointed out that when this zonular precipitation takes place in urine of normal reaction[1] the presence of bile salts *along* with albumen or a proteid may be inferred. This urine is a good example of the fact, for the precipitate is very copious, though the urine is diluted fourfold. In order to obtain a notion of the amount of the bile salts by the peptone test in urine containing blood or the elements of blood, it is necessary to boil it (being at the same time careful *not to* add acetic or any acid either before or after the boiling), when the hæmoglobin and albumen coagulate, as in this example, into brown masses, and then to filter; this done, the diluted urine before us produces the standard opacity when only four minims are added to sixty minims of the test solution, so that I take it the bile salts are *1500* per cent. in excess. Furthermore, the boiled and filtered urine produces a good reaction with Pettenkofer's test, as you observe.[2] By the side of the tube showing Pettenkofer's reaction, I place another showing the dense zone of precipitated peptone induced by the diluted urine on which the peptone test solution has been run. I can but refer to what the examination of one specimen of hæmoglobinuric urine suggests; whether or not *the same observations can* be made in other cases remains to be seen.

---

[1] The specimen under examination is acid. When the urine is alkaline, the zonular precipitate from a citric test-paper dropped into it may arise from an alkaline modification of albumen, as well as from albumen along with bile salts.

[2] Inasmuch as there are no trustworthy means by which the results obtained by any new test for bile salts may be checked (otherwise, I suppose, there would not exist the need for a new test at all), one must fall back on broken reeds. The tests introduced by Casali (oxidising agents, barium peroxide, stannous or antimonious chloride, along with sulphuric acid)

An important observation was made by Dr. George Harley respecting the albumen of hæmoglobinuria, which now, in this sample at least, receives explanation if bile salts are present as well as albumen. This observer remarked that the albumen was readily dissolved by a slight excess of acid,[3] and that is so in the urine before us. The fact is indeed shown by the zone which appears on dropping into the diluted urine a citric test-paper, the excess of acid at the bottom of the tube preventing the appearance of the precipitate there. The following observation of Dr. Wickham Legg is also very important in connexion with the presence of bile salts in hæmoglobinuric urine; the urine of a gentleman who had an attack while under examination was immediately put under the microscope, when, says Dr. Legg, "there was no difficulty in recognising many red blood-corpuscles. The urine was set aside till the next day, when it was again examined. This time I could not discover a single corpuscle."[4] Other observers have likewise detected the same fact, and if you place under the microscope a drop of blood along with a solution of bile salts you will witness what in all probability takes place in hæmoglobinuria, either before the urine is voided (for there are cases in which not a blood-disc can be detected in the freshly discharged urine) or after its emission.

I have already referred to the effects of catching cold in increasing the normal discharge of urinary bile salts. Is the hæmoglobinuric patient, because of some curious susceptibility to chilling, an example of this fact on so large a scale that bile salts are let loose, as it were, from the portal organs into the systemic blood, so as to discharge the hæmoglobin from an immense number of the blood-discs? I have pointed out the association that appears to me to subsist between the increased urinary elimination of bile salts and ague, as well as the diseases of that organ of ever-varying capacities—the spleen; and I am inclined to view these observations as at least interesting, if not suggestive, when studied by the side of the symptoms and pathogeny of hæmoglobinuria.[5]

(*b*) *Scurvy.*—In the four cases examined there was a large excess. I show you the urines of two convalescent cases of scurvy which I lately saw at the Seamen's Hospital, Greenwich; they both contain over 200 per cent. increase of bile salts.

Capillary hæmorrhage is also a prominent feature of the cholæmia of jaundice, leucocythæmia, diseases of the liver and spleen, and of fevers—at the onset especially. The epistaxis of hepatic disease, and of cardiac disease inducing congestion of the liver and spleen, will doubtless occur to your minds as a probable example of a cholæmic hæmorrhage. May not cholæmia be sometimes a determining cause of cerebral hæmorrhage—as perhaps especially in those cases in which apoplexy follows an unusually hearty meal? In animals which succumb to the intravenous or subcutaneous injection of bile salts the blood is found imperfectly clotted. This defect in the coagulability of the blood of the cholæmic—a fact which has frequently been recorded post mortem—suggests an explanation of the liability to alarming and persistent hæmorrhages which these patients not unfrequently exhibit after some trifling operation, such as the extraction of a tooth; and furthermore, may it not be a factor in some cases of menorrhagia and flooding?

7. *Cardiac asthenia.*—The biliary salts greatly reduce the force of the heart's action, and the frequency also, if the patient is fever free, or there is no cause of reflex irritation present. The fact is sometimes well illustrated by the slow and feeble pulse of jaundice. But my observation leads me to view the depressed cardiac action of cholæmia as not only of pathogenic interest, but of some practical importance under special circumstances—such as the administration of anæsthetics. At any rate, this appears to be the teaching of a late well-attested experience. An anæmic patient, about twenty-five years of age, whose urine had contained during the preceding three months from 100 to 150 per cent. increase of bile salts, went to her dentist in Leeds, without consulting me as to the advisability of inhaling an anæsthetic: and the dentist wrote me as follows: "Leeds, April 14th, 1885.—I have just had Miss X——, a patient of yours, with me, to have a lower molar tooth and an upper bicuspid root removed under nitrous oxide gas. I have administered it to her before, with the usual results. To-day all went well until I was just on the point of operating, when the breathing suddenly stopped and she collapsed. By a prompt use of the ordinary means of restoration she recovered, and after half an hour's rest did not appear anything much the worse, except that she continued to feel faint." It is surely worth while to keep such a fact as this in mind. In this case there were no signs of recognisable organic disease of the heart or other organs.

II. *The urinary elimination of bile salts is insufficient.*—Hitherto I have spoke of an excess of bile salts in the urine: I now come to consider the possible, if not probable, condition implying retention of these elements in the blood from imperfect evacuation of them by the excretory channels—kidneys, bowels, and skin. To decide this question demands a much larger experience than mine, and the accumulation of a multitude of carefully recorded facts, such as are not at present at my command. Hence every position that I advance I look upon as merely suggesting either a standpoint or a point of departure for further observation. I would divide the cases into two classes—namely, those in which the bile salts are present in great excess in the blood and the elimination of them by the kidneys is checked or rendered defective; and those in which the production of them is not excessive, but the renal discharge is subnormal. In all there must be a persistent and increasing retention of these excrementitious matters in the blood; perhaps only now and then relieved by the vicarious efforts of the bowels or skin, or by an occasional spurt, as it were, of the kidneys.

The production is increased but the elimination is inefficient.—When the systemic blood is greatly surcharged with bile salts—as in fever, jaundice, and certain forms of anæmia,—the patient, it would seem, is as a rule safe from acute poisoning so long as the kidneys discharge them with freedom. It is true he suffers all the while from the textural degenerations induced by the presence of them in excess in the blood; but while the charge of them is kept down below a certain dose, as it were, by efficient elimination, he runs no risk of imminent danger. It is otherwise when the kidneys and the *other emunctories fail to bale out the pernicious material*; for then it accumulates and effects further destruction of the cellular elements, and may even reach that percentage proportion which experiment has shown will induce convulsions and coma—a catastrophe which may, however, be averted for a time by a vicarious evacuation from the bowels or the skin, or perhaps by blood-letting. In high fever, especially at the onset in children, *this is by no means an uncommon event*;[6] and it is possible that now and then a fever patient has been sacrificed by the injudicious checking of a critical or vicarious evacuation. It is likewise occasionally met with in jaundice; when the patient unaccountably becomes apparently uræmic, or at any rate he is seized with convulsions and dies comatose. It is, therefore, of some practical importance, whenever there is a large proportion of bile salts in the blood—as, for example, in fever and jaundice—to see that the renal elimination of these noxious constituents is sufficiently free; and when a decided falling off takes place, while the fever is high or the jaundice is unabated, the observer should be ready to assist evacuation by other channels, and should be on his guard not to check a salutary discharge.

In chronic cholæmia my experience inclines me to think

---

have proved worthless in my hands for urinary observation; and the evidence of Pettenkofer can only be taken for what it is worth, for it is easy to prove that it reacts with albumen. But my observation on the reactions provided by albumen and by bile salts with Pettenkofer's test has led me to recognise a difference, the purple zone of albumen appearing at once either at or more generally just above the line of contact of the urine with the sulphuric acid, and freely diffusing itself upwards into the urine, while the colour reaction with bile salts requires time, is rarely immediate, and appears in the upper layer of the sulphuric acid, there often appearing a clear space between the zone and the urine. A point of great practical importance in using Pettenkofer's test is to prevent charring by inserting the tube at once into cold water after running down the sulphuric acid.

[3] Med.-Chir. Trans., vol. xlviii., p. 170.

[4] On Paroxysmal Hæmoglobinuria, St. Barth. Hosp. Rep., 1874, p. 77.

[5] I am inclined to think that hæmoglobin is present in the cold infusion of the splenic pulp. The elasticity and contractility of the envelope of the spleen, its amenability to reflex contraction, and its capacity of dilating to a large size, are, I think, important physiological facts to be duly weighed in our reasonings about hæmoglobinuria. (See Addendum.)

[6] The reader will bear in mind that in children under six years of age the liver weighs more in proportion to the body weight than obtains in after years.

that a check to the renal elimination of the bile salts may lead to retinal or other hæmorrhages, or to some similar results of the toxæmia. For example, an anæmic girl who for some months had been discharging a considerable excess of bile salts by the kidneys, one day complained of some curious sensations about the left eye, when I found the renal discharge of the biliary elements had gone down to nearly the normal amount. Suspecting that a retinal hæmorrhage had taken place, I sent the patient to Dr. Hartley of Leeds for his independent report, which amply confirmed my suspicion.

(*To be continued.*)

ONE HUNDRED CASES OF VARICOCELE TREATED BY THE SUBCUTANEOUS WIRE LOOP.

By RICHARD BARWELL, F.R.C.S.,
SURGEON TO CHARING-CROSS HOSPITAL.

ON the 10th ult., two lads, Henry B——, aged seventeen, and John J——, aged sixteen, came under my care for the cure of varicocele, which had caused their rejection by the examining officers of Her Majesty's navy. On April 16th I performed on these lads the operation which I introduced some years ago—viz., that of passing subcutaneously round the veins a wire loop, which, being tightened every other day, first occludes and then slowly cuts through them. In the case of Henry B——, this process was completed and the wire came away on the thirteenth day; in the case of John J——, on the fifteenth day. In neither case was there any suppuration or swelling, and only momentary pain at the times of tightening the wires. I have already described the method of operating,[1] and shall therefore on the present occasion give a very brief account of the procedure, the object of this communication being to analyse the results of 100 operations which I have now performed.

The only instruments required are a needle armed with about ten inches of silver wire, gauge twenty-six, or even a little less; a pair of pliers, and an oval shield of vulcanite, one-eighth of an inch thick, with a long diameter of an inch, a short one of about three-quarters of an inch. Near each end is a brass upright, projecting a quarter of an inch. Close to the spots where these uprights are fixed the shield is perforated by oblique channels which open on the other side near the centre. The surgeon must very carefully separate all the veins from the vas deferens, and squeezing together between his left thumb and index the two sides of the scrotum, he keeps the duct and the spermatic artery behind and the veins in front. He then thrusts the armed needle through that half of the scrotum from without inwards, thus placing the silver wire between the above-named parts; he then reintroduces the needle at the previous hole of exit, and when its point lies within the scrotal cavity he relaxes his grasp on that part, and partly by passing the needle onward, partly by manipulating the veins behind its point, he brings the original opening of entry towards it and extrudes the needle. It is only necessary to be sure that no veins escape, and that no part of the lining fascia of the scrotal cavity is included. When these manipulations are completed the veins are encircled by a loop of wire, the ends of which hang out of one puncture at the outer side of the sac. These ends are passed each through one of the holes in the shield, and when drawn sufficiently tight are secured by twisting them round the uprights. It is well, however, to place three or four folds of lint—or better still, a piece of felt, in which a slit has been cut—between the shield and the skin. Every other day the wire must be unwound from one of the uprights,[2] tightened, and replaced. Thus it acts as a very slow écraseur and cuts through the veins in some time between eight and sixteen days, according to the bulk of the varicocele.

Of the 100 cases operated on by me in hospital and private practice I have kept notes; their analysis is as follows:—In no case was there any bleeding, shivering, pyrexia, erysipelas, or other disquieting manifestation. In 16 there was slight suppuration; in 15 of these the pus found its way out along the wires, and gave rise to no trouble; in 1 a little abscess formed in the thickness of the scrotum and was evacuated by an incision one-third of an inch long. In 12 there was a little ulceration where the shield pressed against the skin; it healed when the wire came away. In 1 there was some orchitis, which lasted five days. In 71 there were none even of these trifling complications, the course of events being precisely like that of the cases above recorded. Three patients would not submit to be confined, but walked out after the second day; one of these belonged to the class in which some suppuration occurred, the other two to that in which no complication took place.

The above may be termed the immediate effects of the operation. There remain still to be considered the remote or ultimate result, and therewith the conditions previous to operation.

A (1 case)—Testicle only represented by a small pultaceous mass; the bunch of veins considerable, larger than the gland. (Patient aged twenty-seven.)

B (13 cases).—Testicle very soft and small.

C (47 cases).—Testicle much diminished and of considerable softness.

D (32 cases).—Testicle somewhat diminished and soft.

E (7 cases).—Slight varicocele operated on for the sake of passing examination.

In the first four categories, chiefly in the second, third, and fourth, the organ was the seat of more or less pain; in 23 cases this was severe.

A.—The pain ceased, and the testicle became both a little harder and larger; the patient thought it regained some function. He married five months after the operation, and is the father of four children.

B, C, D.—In every case the testicle became harder, and regained some of its dimensions immediately after the operation, but did not entirely resume its natural consistence and size until after a considerable time: in some of the worst cases, so far as I was able to trace, being as much as two years; in others, and more especially in the younger patients, three months.

E. — The slight cases under this heading passed the examining board very soon after operation.

I lost sight of most of my 100 cases within a few months of operation, chiefly hospital patients, some of whom I never saw again after their discharge. One case (*A*) I even now see occasionally, nineteen years and a half after operation. The left testicle is still smaller and softer than normal; the right one is healthy, and unusually large. Of the 92 belonging to classes *B*, *C*, and *D*, I have only seen 28 at an interval of more than six months after operation. In all of these, except 2, whose testicles were still somewhat soft,[3] a perfectly normal condition existed. One of these cases, a gentleman who had been married fifteen months, had a rather large varicocele; the testicle was very slightly softened; but he had almost constant pain in it, and after coitus this was so increased that he described it as agony. After operation the pain subsided considerably, and in seven weeks had entirely disappeared, nor did it recur. I kept this patient under observation for twenty-seven months. Three others (not included with the above 28) contracted gonorrhœa and one syphilis. Of the former, one had orchitis of the left (very slight) and one of the right testicle. The gentleman who contracted syphilis neglected himself, and remained deeply affected for nineteen months. Since that time he has remained free from any manifestation, except occasionally ulcerated fissures at the side of the tongue.

This is all the information I can give concerning the 100 operations. The safety and efficacy of the procedure are, I think, fairly attested by these results. The very slight degree of pain, either at the time or afterwards, should also be mentioned. I have operated on five cases without any anæsthetic.

George-street, Hanover-square, W.

---

[1] THE LANCET, vol. i., 1869, p. 711; also vol. i., 1875, p. 820.

[2] I have lately modified twisting the wire round the upright, and now fix it by means of a binding screw.

[3] At from six to eight and eight and a half months respectively after operation.

THE agitation and controversy which have for several months existed between the Canterbury Corporation and the owners of some sixty private wells, the supplies from which were condemned as polluted and unfit for drinking purposes, are at length reported to have almost settled down.

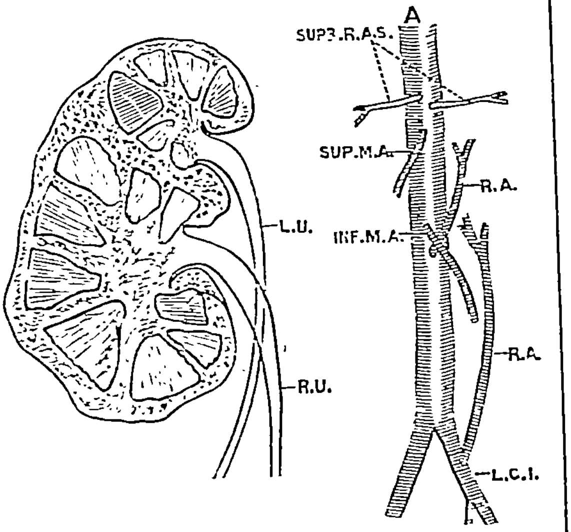
REMARKS ON TWO CASES OF SINGLE KIDNEY.

BY P. W. MACDONALD, M.B. & C.M. ABERD.,
DEPUTY MEDICAL SUPERINTENDENT, DORSET COUNTY ASYLUM.

CASES of congenital absence of one kidney are comparatively rare. Mr. Henry Morris, in an address before the Medical Society of London, said:—"Out of 8068 post-mortem cases there were but two instances of congenital absence, and one only of congenital atrophy, of the kidney."[1] To have met with two cases in less than one hundred necropsies has, judging from recorded cases, been the experience of none, and I have thought the following remarks might be of interest to those who give their special attention to the surgery of the kidneys.

The first case I met with was in 1881. The subject was a male patient suffering from epileptic dementia. He died on April 27th, and a necropsy was made forty-eight hours after death. The brain, lungs, and heart were found to be, as far as the naked eye could discern, normal. Liver large and congested; capsule adherent. Cut surface shiny and dark-coloured; blood oozed out; whole organ soft and probably fatty. Spleen normal. The liver and spleen being removed, I then proceeded to remove the kidneys, and found they were absent from where they normally ought to have been. Reflecting the mesentery and small intestines, one large kidney was found lying on the spinal column opposite the second, third, and fourth lumbar vertebræ. (Fig. 1.) It was enveloped in a natural capsule. It was large, weighing over 11½ oz., and somewhat irregularly shaped. Vascular supply abnormal and large. One branch had its origin from the aorta, and a second one from the left common iliac artery. The branch from the iliac artery, which was the larger, entered at the normal pelvis, and the one from the aorta at the second or smaller pelvis. There were two ureters. One came from the normal pelvis of the kidney, the other from a sort of second pelvis at the upper end of the kidney. Both entered the bladder normally. The one from the smaller pelvis passed behind the one from the normal pelvis, and entered the bladder on the right side (as right ureter). The other ducts and glands in connexion with the prostate were normal. There were two supra-renal capsules, one situated on each side of the eleventh dorsal vertebra, therefore quite unconnected with the kidney. Pelvic organs normal.

FIG. 1.



The second case was that of a female patient, who was admitted into this asylum on Aug. 16th, 1883, and died on Dec. 3rd, 1883. This patient was also the subject of epilepsy. At the necropsy, made twenty-four hours after death, the body was emaciated, and there was slight œdema of the left leg. Head: Thickening and opacity of the arachnoid over the frontal lobes and atrophy of the left superior frontal convolution. Pia mater easily removed. No apparent congestion. Heart large, and muscular structure pale; valves closed. Both lungs were studded with caseous nodules, and there were several rather large cavities in the left lung. There were pleuritic adhesions. The liver was soft and pale. On section, there were signs of commencing fatty changes. The capsule showed whitish patches. The spleen was normal. Intestines normal and no ulceration. On proceeding to remove the kidneys, no trace of the right kidney or ureter could be found. The left lay in its normal position; was large, weighing over nine ounces. (Fig. 2.) The suprarenal capsules were normal. There was one ordinary-sized ureter, which entered the bladder on the left side. There were two renal arteries; one large one coming off from the aorta below the superior mesenteric artery, and a second smaller one an inch below the larger. The larger one gave a branch to the left supra-renal capsule. The right capsule received a branch from the aorta. The kidney was congested, but not otherwise diseased. Pelvic organs normal.

In neither case was it known during life that there was only one kidney present—a fact easily understood when it is stated that in the first case the patient was an epileptic dement, and at no time of his residence in the asylum had he shown any symptom of kidney mischief, and at last died from general decay. The subject of the second case (female) was also suffering from epilepsy with maniacal symptoms, and after a short residence in the asylum succumbed to one of the most dire diseases, phthisis. The œdema of the left leg in this case was due to an enfeebled and embarrassed circulation. It will thus be seen that there was at no time any necessity to make an external examination of the kidneys, and consequently the fact remained unknown till met with on the post-mortem table. The interesting points are the abnormal site of the kidney with its two ureters, in one case, and the large and abnormal arterial supply in both. There would have been much difficulty in arriving at even a probable diagnosis as to the site of the kidney, in the first case, had need arisen to map out the kidney on the living subject, a proceeding which is at no time attended with certainty; for Mr. Luther Holden says: "I have never succeeded in satisfying myself that I have distinctly felt its rounded lower border in the living subject, nor even in the dead."[2] As already mentioned, the kidney was large and irregular. On section it seemed to be one large kidney with a smaller one joined on to its upper end. The smaller pelvis had separate and distinct pyramids, and there was a rather thick cortical layer between them and those of the larger or normal pelvis. The arterial supply was abnormal in both cases, and the branch supplied by the left

[2] Landmarks, Medical and Surgical, p. 33.

common iliac artery would have caused much annoyance in any operation on that artery or in its immediate neighbourhood.

Numerous cases of the congenital absence of one kidney have been met with and reported. Mr. Jonathan Hutchinson, in a clinical lecture[3] delivered at the London Hospital, mentions a case and draws attention to the dangers that may arise in such cases from suppression of urine by renal calculi or any other untoward event. Mr. Gubbin[4] reports a case of complete absence of the left kidney and suprarenal capsule, and quotes a series of cases collected by Dr. Brenner in 1838.[5] Dr. Brenner states that in a third of his cases there was malformation or arrest of development in one or other of the genital organs. Mr. Thomas Wilmot[6] mentions a case of single kidney, and states that the apparent cause of death was the secondary formation of an abscess in the kidney. In 1878 Beumer collected a series of cases, and drew attention to the effect of the absence of one kidney on the sexual passions. In the literature on the subject to which I have had access I fail to find a reported case of single kidney with two ureters. Notwithstanding that such cases are rare, it is, nevertheless, necessary in these days of advanced abdominal surgery to recall and bear in mind such important abnormalities, for a timely thought in this direction might save both surgeon and patient from unpleasant recollections.

Dorset County Asylum.

ON AURAL EXOSTOSES.

BY GEORGE P. FIELD, M.R.C.S.,

AURAL SURGEON TO ST. MARY'S HOSPITAL.

THE following four cases of exostosis in the auditory canal have been recently under treatment by me. I now place them on record—first, because they afford further demonstration of certain important facts which I have already insisted on—namely, that ivory aural exostoses can be successfully removed, not only without great risk, but with decided benefit to the patient, relieving him sometimes of grave cerebral symptoms, and, as a rule, completely restoring the power of hearing; secondly, because I find that it is still customary to inform persons afflicted with these growths that they must make up their minds to endure permanent deafness, the dangers of any possible operation for their relief being such as to render it entirely unadvisable. How contrary to actual experience is this latter statement has been well shown by my first case, that of Dr. G. M—— of Waterford, operated on in October, 1877, and described in THE LANCET for July 20th of the following year. As I have there remarked, the patient, when I first saw him, was suffering from extreme depression of spirits; for, knowing each of his ears to be completely obstructed by a dense bony tumour, he felt himself to be for life debarred from the pleasures of society. The result of operation in his case was thorough restoration of hearing, which now, after the lapse of eight years, remains as good as ever.

The origin of ivory aural exostoses has been repeatedly attributed to gout, rheumatism, or syphilis, alone or combined; but, as I first pointed out in the discussion of my earliest case, a certainly far more general cause is a chronic inflammation of the walls of the external meatus, such as might be produced by habitual sea-bathing. The Hawaiian islanders, as readers of works of travel are aware, are practically amphibious; and Professor Wyman has directed attention to the significant frequency of ivory exostoses in the external auditory meatus of their crania. The four cases that I have operated on during the past three months, I have been interested to find, afford evidence of one and the same exciting cause—persistent sea-bathing. A former opinion of mine, that hereditary predisposition might be excluded from the probable sources of ivory aural exostoses, I have had occasion to modify to some extent; for one of my most recent patients is a younger brother of my first case, and suffered in an exactly similar way from exostoses in both ears, though happily, unlike him, requiring only one operation for their extirpation, instead of repeated treatment occupying altogether seven hours; it must, however, be noted, that both patients had for years been accustomed to bathing in the sea three or four times a day. In hospital practice I have, as others, remarked, the absence of instances of ivory aural exostosis, whereas the softer growths are not infrequent. Seemingly another peculiar feature in connexion with the disease is that in certain districts it is commoner than in others. Thus, I have had four cases from Waterford, three from Ipswich, several from the south of Ireland, and one each from Hull and West Hartlepool, &c. The operation of drilling the tumours with the American dental engine, as first suggested by Dr. Arthur Mathewson of New York, I have more than once described.[1] For further information as regards the varieties, mode of occurrence, and characteristics of osseous tumours of the meatus, I would refer to the third edition of my book, p. 69.

I will now proceed to give, as briefly as possible, an account of my four most recent cases.

The first is that of Mr. W. G. D. G——, aged forty-six, a gentleman living near Waterford, whose history I do not think I can do better than give in his own words, as follows: "I was first troubled by an abscess in my right ear in Sept. 1883, the effect, probably, of sea-bathing, and the frequent use of an old spring-board some beggar put up on Kelly's Rocks, evidently for the benefit of the medical profession. The abscess caused deafness for some three or four weeks, but was eventually cured by the application by Dr. O'Farrell of a solution of caustic. In October, not being satisfied with the feel of my ear, I consulted Mr. Fitzgerald in Dublin, who said the passages in both ears were much contracted, and I might eventually have to get them operated on. He prescribed a lotion, which I used for some time, and hearing came back all right. In 1884 I was yachting from the middle of May till the end of September, and took a header or two off the main boom each morning. At the end of the season I was again troubled with an abscess, this time in the left ear, causing deafness. At the end of November I consulted Mr. Field, who diagnosed double ivory exostosis. After the removal of a polypus from the left ear its hearing returned; but the exostoses had now so increased that, as soon as I could spare time, early in February, I had the worse ear, the left, drilled, the operation lasting sixty-five minutes. In consequence of leaving London before the ear was sufficiently healed, it became filled with granulations, which gave much trouble to get rid of from the beginning till near the end of March. On the 9th of that month the other, or right, ear was operated on, chloroform being administered for one hour and ten minutes, and in it also hearing is now (April 11th) nearly restored." I may add to this account that by April 25th audition was quite perfect in the left ear, and well nigh so in the right.

The next case is that of Mr. S. W——, aged twenty-six, sent to consult me by Mr. Swannick, of West Hartlepool, in Nov. 1883. He was then suffering from slight deafness of both ears, caused by the presence of exostoses, which I suggested should be removed if they gave rise to any further trouble. When, in Feb. 1885, he came back to me, I found the left external meatus considerably lessened in calibre, and the right almost completely blocked by the exostoses. I had now no hesitation in recommending early extirpation of the growths. On Feb. 24th, chloroform having been administered, I succeeded, after fifty minutes' labour, in effectually drilling through the obstruction in the right ear. The patient recovered well from the operation, and had one or two returns of his nocturnal giddiness during the next few days. My colleague, Dr. Broadbent, who saw him, kindly gave me the following opinion of his case:—"Mr. S. W——'s attacks may be conveniently called epileptiform, but they have not the character of epilepsy proper, inasmuch as there appears to be neither convulsion nor loss of consciousness. I am disposed to fear that they differ in a more important respect, and that they are attended with danger to life. I do not think, however, that, like some of the cases recently reported, the attacks are due to the slow pulse with which they are accompanied. In my opinion they are cerebral in origin, and the retardation of the pulse is secondary. I did not find much on examination which threw light on the case. The optic discs were small and pink and without sharp outlines; and the retinal veins were large; but there was no neuritis. The right temporal artery was more conspicuous than the left, and pulsation was visible in it. It is quite possible that the attacks may have been due to the exostosis which you have removed, especially if secretion had accumulated behind it; but time alone can decide this. The case puts me strongly in mind of one that I saw many years since. The attacks, one of which I witnessed, corresponded closely with the description given by Mr. S. W——, and the intellect was unimpaired to the last. The patient died in an attack, and on examination there was found tremendous thickening of the frontal bone. In any circumstances it was right to remove the exostosis; and I shall be greatly interested in the result." The result was so far satisfactory that the hearing became quite restored in the ear operated on, and the patient, after a month's absence, went home apparently quite well. On the 29th of April Mr. Swannick wrote to me as follows:—"Since his return he has had a few fits, one of which, at evening service on Sunday, was severe. From that date till now I have been giving him bromide of potassium three times a day, and he has had only one slight attack. The gloominess and depression that come on every evening at about 7 o'clock are diminishing, and he feels altogether happier. The only question that now arises is whether the second ear (the left), which is almost closed, should be operated on."

The next case, that of Dr. W. L. M—— of Waterford, brother of Dr. G. M——, operated on eight years ago, as above mentioned, is thus described by the patient himself:—"W. L. M——, a medical man, aged thirty-five, strong and healthy, has been all his life a great sea-bather. He has never had syphilis. In August, 1884, he first began to experience a disagreeable 'fulness' in the ears, most marked in the left; unaccompanied, however, by either pain or deafness. Thinking this was probably caused by the presence of wax, on Aug. 19th he syringed out the left ear with warm water, rendering it immediately very deaf. As during the next few days hearing was not recovered, he became uneasy; and on the 22nd he consulted Dr. Storey in Dublin, who diagnosed a large exostosis in each ear, with irritation and inflammation of the left meatus. A solution of nitrate of silver (ten grains to the ounce) having been applied daily, the patient on the evening of the 28th recovered his hearing. Mr. Field, whom he saw in London on Sept. 22nd, confirmed Mr. Storey's diagnosis. The exostoses were then both of considerable size, that in the right ear being the larger; but as there was still ample room for the passage of sound, Mr. Field recommended him to report himself at intervals, so that the progress of the disease might be observed. For the next few weeks no inconvenience whatever was experienced. On Oct. 23rd, when Mr. Field was again consulted, there was evident, but still only very little, enlargement of the right exostosis, while that of the left was scarcely perceptible. On the occasion, however, of the next visit, on March 12th, 1885, although hearing had in the interval continued perfect, and no distress or pain had been suffered, Mr. Field advised an operation without further delay, both exostoses having increased so much that an extremely constricted space remained for the admission of sound. The patient accordingly went home, and, having made the necessary arrangements for remaining in London, returned thither on March 24th. On the same day Mr. Field operated on both ears. The exhibition of chloroform, which lasted fifty-five minutes, was not followed by any sickness, pain, sleeplessness, or lack of appetite. There was, however, great deafness, and on the day after the operation healthy pus was discharged from both ears. On March 27th the patient was able to be up, and on the 30th he called on Mr. Field in his own house. On April 16th whilst still very deaf he removed from London. On the day following the left meatus cleared up sufficiently to admit of distinct hearing for about three hours, the right improving in a less degree. During the next fortnight hearing was very variable, being sometimes perfect with the left ear for hours, at other times absent for days together." On the return of the writer of the above from Ireland, on May 8th, to see me again, I found the ears still somewhat swollen but presenting plenty of room for the passage of sound. The curious feature in this case is its exact resemblance in symptoms and in the gradual recovery of hearing by both ears to that of the brother, Dr. G. M——, already alluded to.

My next instance of removal of aural exostosis is afforded by Mr. H. C. W—— of Ipswich, aged twenty-five, who has furnished me with the subjoined account of himself previous to the operation:—"It was in May, 1881, that I first felt inconvenience in hearing, but my deafness, which was not total, passed off in some four weeks. In January, 1882, I gradually lost all use of my right ear; and during the end of February and early part of March I had much pain in it, which my doctor could not relieve. On the 28th of last month I called on Mr. Field, who told me the ear would require an operation. He gave me a lotion which almost immediately relieved my pain, and after applying this thrice a day for some three months my hearing returned. Subsequently, until December, 1884, I was able to hear perfectly, although conscious of something in the ear which prevented one from pulling it about with impunity. In that month I grew quite deaf; and in March, 1885, I began once more to suffer pain, which was very acute. When, on April 13th, I for the second time consulted Mr. Field, he pronounced an operation absolutely necessary, and this, on the 21st, was performed." It remains to be added that in this case the growth was very large, and, after the use of the drill, had to be broken up with bone forceps,[2] in a manner similar to that described in THE LANCET, April 1st, 1882. The patient recovered well from the operation, which lasted sixty-five minutes. His hearing is now (May 10th) almost perfect, and in a few days he will return home.

A consideration of the above and other cases leads one to the following general conclusions with respect to ivory aural exostoses:—1. They are by no means necessarily associated with a rheumatic, gouty, or syphilitic diathesis. 2. Their causation can, with strong probability, be ascribed in many, if not in all, cases to some local irritation of the external auditory meatus, such as may be set up by habitual sea-bathing. 3. They can be most efficiently treated only by drilling, which with proper precautions—notably the use of a pliant and not brittle steel guard to protect the ear in the event of slipping of the drill—is a perfectly safe operation. 4. Their prompt removal is indicated in all cases where (*a*) they hinder the elimination of secretions and discharges from the auditory canal; (*b*) where they occasion pain by pressure on neighbouring structure; (*c*) where they threaten completely to block the meatus, and so to deprive the patient partially or wholly of hearing.

Lower Seymour-street, W.

THE BULLÆ OF PEMPHIGUS.

BY GEORGE THIN, M.D.

IT has been stated by Gibier[1] that acute pemphigus is due to a parasite. The microbe of acute pemphigus, according to this author, presents a beaded appearance when fully developed, the elements being grouped in rows consisting of two to twenty joints. Development takes place from minute spherical bodies isolated or irregularly grouped, or contained in zooglœa. This organism was found in the liquid of the bullæ, and in the urine of the patient who formed the subject of his investigation. In the liquid of the bullæ in a case of chronic pemphigus the same author found a few bacteria moving slowly (*rares bactéries à mouvements lents*).

In a well-marked case of pemphigus in which I have recently examined the fluid of the bullæ I was unable to discover any organism.

A tall strong man, aged fifty-two, who had always enjoyed good health, consulted me on February 3rd, 1885, on account of an eruption. He stated that two months previously he had a rigor, and that within the next two or three days several "bladders" appeared on his forehead. Others then came out on his chest, arms, and legs, and had continued to appear more or less ever since. I found his face, neck, temples, and ears the seats of a bullous eruption, which in the aggregate involved on the lower part on the face more than half the surface. There were also several bullæ on the chest, back, arms, and legs, some being full of clear serum, some collapsed, and some burst, leaving a red moist surface covered with folds of epidermis. His general health was not perceptibly impaired. Fresh bullæ continued to come out, and I had an opportunity of observing them in the earliest stage from their first appearance as minute, scarcely raised, vesicles, not much larger than a pin's head, with a central depression, and as large bullæ about two inches long, three-quarters of an inch broad, and about half an inch high.

---

[2] This was one of those cases which may be dealt with by the use of a chisel and hammer, or, as I prefer, by bone forceps, for the exostosis was not so hard as in the three cases just described. A large quantity of bone was removed from this patient's ear, and the external auditory meatus afterwards looked large and open. The chisel I believe to be absolutely useless for ivory exostoses, and nothing but the drill, which makes only a small orifice (quite sufficient for the passage of sound), is of any service.

[1] Annales de Dermatologie et de Syphilographie, vol. iii., p. 102.

On three separate occasions I examined the fluid of the bullæ microscopically without observing any organisms. I also prepared a number of cover glasses, on which the fluid was dried in the now familiar way, and the glasses, after being heated, were floated on solutions of aniline dyes and properly prepared for examination. No organisms were stained. In one preparation, examined fresh with the addition of a solution of gentian violet, some epidermic cells were found in the fluid, and to one of these micrococci were found adherent. The results of examining the fluid of the bullæ, both fresh and after being dried and stained, were thus, so far as organisms are concerned, entirely negative. A few white blood-corpuscles were found in the fluid. On Feb. 6th and 10th attempts were made to cultivate any organisms that might be present. The bullæ were opened largely with a purified lancet. A pure platinum wire was plunged into the depths of the bullæ, and tubes of sterilised gelatine-peptone meat infusion inoculated in the usual way. Two neutral, two alkaline, and one acid tube were thus inoculated and put aside at the ordinary temperature of my laboratory. Up to April 13th nothing had grown in the tubes, the gelatinised meat infusion having in the meantime become considerably shrunk.

These observations do not prove that no organisms are present in the fluid of the bullæ of chronic pemphigus, but they tend to show that typical pemphigus may exist without the presence in the bullæ of organisms which can be put in evidence by the methods on which reliance is now placed. The organisms described by M. Gibier could not have been present in my case.

Queen Anne-street, W.

A CASE OF LUMBAR COLOTOMY.

By WILLIAM DOBBIN, M.A., M.D., &c.,
MEDICAL OFFICER, BANBRIDGE DISPENSARY.

ON March 24th, 1884, I visited a dispensary patient, Elizabeth L——, aged seventy, married, residing at Tullyrain, near Banbridge. She was a tall woman, emaciated and cachectic-looking, but was not confined to bed. She stated that she was troubled with piles, and had suffered from painful defecation, attended with a bloody discharge, for nearly three years. Lately her condition had become much aggravated as the constipation was more difficult to overcome, and there was much distressing tenesmus. On examination I found that there was a small tumour of stony hardness at the posterior margin of the anus, which doubtless had been formerly a pile, but was now a mass of scirrhus. The sphincter was a rigid circle which would admit only the tip of the finger, the introduction of which caused extreme distress. Per vaginam I found that a hard nodulated mass extended upwards for some four inches, projecting into the vagina in front and apparently encircling the lower end of the rectum. Avoiding mention of the dreaded word cancer, I told the patient that the only mode of relief was by an operation, but that it might be delayed for some time if she were careful to keep the stools soft by castor oil. An occasional opiate was administered when the pain was very severe, and I kept her under observation, visiting her from time to time when in the neighbourhood.

Matters went on without much marked change for nearly four months, when, on the 17th of July, I received a message saying that she could not bear her condition any longer, and that she would submit to any operation for relief. As soon as possible I proceeded to her house accompanied by Dr. Smyth, J.P., and Dr. Tweedie of Banbridge, who kindly afforded me their valuable advice and assistance. They concurred in the diagnosis of malignant stricture of the rectum, and agreed that lumbar colotomy ought to be performed at once. Chloroform having been administered, the colon was opened in the left loin by Callisen's operation as modified by Mr. Bryant, all of whose directions in the various steps of the operation were carefully followed. Hardly a tablespoonful of blood was lost. Some difficulty was experienced in seizing the gut, as rather unexpectedly it was found to be empty. After the sutures were fastened the part was dressed with carbolised oil on lint, a pad of oakum was applied, and the whole secured by a binder. Ordered to have milk diet for a few days, and fifteen minims of tincture of opium in half an ounce of water every four hours.

July 18th.—The patient has passed a good night, and feels very comfortable. Pulse 80; tongue clean; skin cool; no pain or tenderness. Wound dressed; looking healthy. Ordered five grains of compound ipecacuanha powder every four hours in place of the draught.—19th: Wound dressed. The patient feels very comfortable.—20th: Wound dressed. A good deal of flatus has passed through artificial anus, but no fæces. Flatulent distension complained of; a linseed-meal and mustard poultice to be applied to abdomen. In addition to anodyne powders, to have a grain of quinine three times a day.—21st: Wound dressed. Since last visit there has been a free discharge of semi-fluid fæces through artificial anus; abdomen much less distended; some appetite for food; in good spirits. Compound ipecacuanha powder to be discontinued, except five grains at bedtime.—22nd: Wound dressed; free discharge of fæces continues; sutures removed; most of skin wound healed by first intention; opening in bowel firmly united to skin.—23rd: Wound dressed. Discharge of fæces has been enormous since the middle of the night; a good many scybala have passed.—24th: Wound dressed. Since last visit fæces have passed in large quantity, but have now ceased. She is clean and comfortable, and is in good spirits.—25th: Since last visit a small quantity of fæces passed per vaginam. This happened only once.

On July 28th, during the night, the patient's husband, who alone lived in the house with her, died suddenly in the bed beside her; and the poor creature, being dreadfully frightened, made her way in a half-dressed state to the house of a relative, who lived about half a mile off, for the purpose of seeking assistance. Fortunately, the journey did her no injury, although she fell several times. After the fatigue passed away she made a capital recovery. A pad of fine tow was kept constantly over the artificial anus, and was fastened in position by a binder. A new pad was applied after each action of the bowels, which took place usually once in the twenty-four hours. Under these circumstances the woman's health continued fairly satisfactory till the end of October, when a large abscess formed and discharged in the left hip. From this period she gradually became weaker and more cachectic, and finally sank on Nov. 24th, four months and seven days after the operation.

Remarks.—Surgical interference without doubt prolonged the life of this patient. It not only relieved her from painful and exhausting straining efforts at defecation, but retarded the progress of her malady by preventing the irritating passage of the fæces over the diseased bowel. What is more important still, existence was rendered endurable and the woman was enabled to end her days in comparative comfort. After the first week she told me she was easier than she had been for two years, and that she was already more than compensated for submitting to the operation. Such a result is ample justification for operating, and I should have no hesitation in recommending colotomy in a similar case. The operation is not excessively difficult, if Mr. Bryant's directions as given in his work on the Practice of Surgery are carefully attended to, and it is not more dangerous than herniotomy, if done in good time. There is no necessity for a patient the subject of artificial anus to wear any special appliance, since a pad of fine tow is quite sufficient. It is cleanly, cheap, and a fresh one can be put on whenever required. I have reported this case, occurring in the practice of a country surgeon, as it may encourage others similarly situated to carry out a serious operation even in the confined bedroom of a dispensary patient.

Banbridge, co. Down.

DR. G. E. PAGET.—At the next quarterly meeting of the governors of Addenbrooke's Hospital, the Lord-Lieutenant of the county will, on behalf of the governors, be asked to accept a bust of Dr. George Edward Paget, F.R.S., Regius Professor of Physic in the University of Cambridge, which has been provided by the subscriptions of a large number of persons, the list being headed by his Royal Highness the Prince of Wales and his Royal Highness Prince Edward of Wales.

GUY'S HOSPITAL.

SURGICAL CASES UNDER THE CARE OF MR. BRYANT.

OF the following cases, the hernia, which was under the care of Mr. Bryant, is an example of an unusual condition of the hernial sac and position of the intestine, for which it is somewhat difficult to account without a history of taxis. The case described by Mr. Bond is uncommon. There is a similar condition illustrated in the article on Hernia in "Holmes's System of Surgery," vol. ii. The series of abdominal operations performed by Dr. Wallace are interesting and important.

CASE 1.—*Intra-parietal Strangulated Inguinal Hernia; Operation; Recovery.* (Reported by Mr. Rymer.)—Maria E——, aged fifty-three, was admitted into Lydia ward on Oct. 4th, 1884. The patient is healthy, and has had twelve children. She has had a slight rupture for years; it appeared after a strain. She kept her bed at first for about a week, and has worn a truss pretty regularly since. On the 3rd she neglected to put on the truss, and the rupture came down. She applied the truss, and the rupture appeared to go up, but she felt uncomfortable all day, and in the evening was sick. She did not sleep all night. Next morning she was sick again, and the vomit appeared fæcal.

On admission, when the patient was lying on her back in bed, no external signs of rupture were visible, but upon manipulation a tense swelling could be felt in the right inguinal region behind the abdominal muscles, above and external to the internal ring. The patient had another fæcal vomit. She was given chloroform, and an exploratory incision was made about an inch in length over the middle of Poupart's ligament, and one inch above it. The inguinal canal was laid open and the internal oblique and transverse muscles divided. When the sac was reached it appeared very much to resemble the tunica albuginea of the ovary. When this was opened a small quantity of bloodless fluid escaped. On careful examination this sac proved to be the old inguinal sac, hardened and thickened by the constant pressure of the truss. The finger was introduced and another large sac was felt. This sac was well slit up with a pair of scissors, and at one point there was a ring which admitted the finger into the peritoneal cavity. This ring was freely divided. Now the intestine could be seen, and was taken up and pushed back into the abdomen. The parts were put into apposition and held by three gut stitches, and the wound dressed with a pad of iodoform gauze and a sponge. This unusual appearance was seemingly caused by the constant pressure of the truss having broken down the band of the first sac and forced the intestine into a second sac, which was formed between the peritoneum and the iliac fascia. The patient had diarrhœa after the operation. A one-grain opium pill was given; ice to suck.

Oct. 5th.—Patient has not been sick since the operation; she feels easier. Wound dressed; there was very little discharge.

7th.—Diet: milk, beef-tea, bread-and-butter.

8th.—Bowels acted once yesterday; no diarrhœa. Wound appears somewhat swollen and inflamed.

10th.—Part of wound has healed by primary union; the inner part gapes a little; patient is in no pain.

12th.—Discharge rather purulent.

20th.—Wound very healthy.

24th.—Wound entirely healed.

Nov. 4th.—Patient has a well-fitting truss. Got up in the evening.

8th.—Went out apparently quite well, except for a cough.

CASE 2. *Dislocation of the left Knee-joint Outwards; Reduction; Cure.* (Reported by Mr. Paget.)—Philip D——, aged forty-eight, an ostler, was admitted into the Accident ward on Oct. 1st, 1884. The patient was leading a horse when it became frisky and knocked him down, twisting his leg He could not rise, and was brought to the hospital.

On admission there was dislocation of the left tibia and fibula outwards off the internal condyle of the femur. There was effusion of fluid into the knee-joint. Under chloroform the leg was flexed upon the thigh, and then extended with traction inwards, the thigh being held outwards. The bones slipped easily into their place. The fibula appeared a little loose. The leg was put upon a back splint with foot-piece, and cold, by means of Leiter's tubes, applied to the knee. One-sixth of a grain of morphia in solution was injected subcutaneously.

Oct. 2nd.—Did not sleep well. In a good deal of pain.

3rd.—Still in a good deal of pain, and there is considerable effusion into the knee.

21st.—Effusion going down. Ice bag still on.

28th.—Knee still feels hot. Left knee measures 14½ in. round; right knee 13¾ in.

Nov. 4th.—Bavarian splint put on.

14th.—The circumference of both knees is now the same.

CASE 3. *Lipoma of Scalp; Excision; Cure.* (Reported by Mr. Palmer.)—Henry H——, aged thirty-nine, a coachman, was admitted into Job ward, on Oct. 13th, 1884. The patient has had good health all his life. Twenty years ago he first noticed a swelling about the size of a pea on a level with the tip of his left ear and 2 in. posterior to it. It was pulpy and freely movable over subjacent bone, and not painful; this has gradually increased in size. On admission, the tumour is about the size of a hen's egg—i.e., 3½ in. from above downwards and 4 in. from side to side. It is soft and pulpy; there is no fluctuation; the bone beneath the growth appears to be excavated. The skin is not dimpled, and can be drawn together over it.

Oct. 14th.—Under chloroform, an elliptical incision was made from above downwards. The skin was dissected from either side of the tumour. The integument was found to be much adherent, and it was necessary to separate it down to the base of the swelling. The tumour was then removed, and the wound dressed with iodoform gauze. The growth was a pure lipoma.

21st.—The patient has had hardly any pain or inconvenience from the operation. The upper part has healed by primary union. The remainder is granulating.

Nov. 3rd.—Wound quite healed, and there is no discharge whatever. The patient feels quite well.

This case is worthy of record from the fact of the position of the tumour, lipomata being very seldom met with on the head.

BRISTOL GENERAL HOSPITAL.

CASES OF ANEURYSM IN THE LOWER EXTREMITY TREATED BY DIGITAL COMPRESSION; REMARKS.

(Under the care of Mr. NELSON C. DOBSON.)

CASE 1. *Simultaneous Aneurysm of both Popliteal Arteries.* T. F——, aged forty-three, a healthy, well-made man, a gamekeeper by occupation, and subject at times to considerable exertion in the way of walking and watching, was admitted in 1880. Has had gonorrhœa, but not syphilis; takes freely of beer, but is not a spirit drinker; his father suffers from gout, but the patient has never suffered from this; there is no albumen, and the heart sounds are normal. He states that two years ago he noticed an aching pain in the bend of his left leg, and some time since he discovered a swelling in the ham, which pulsated. He, however, continued to work regularly. Six weeks ago he noticed a similar swelling in the right ham.

When the man came under Mr. Dobson's notice there was an aneurysm in each popliteal space—that in the left being the larger, and measuring five inches in length and three inches in breadth; the swelling on the right side being as large as a hen's egg. Both swellings exhibited the ordinary characteristics of aneurysm, but in both firm pressure of the stethoscope was required to bring out the bruit. There was nothing abnormal about either limb otherwise. No other aneurysm could be discovered elsewhere. The heart was irritable in action, and the whole arterial system seemed to partake of the same irritability, both femorals at the groin pulsating unduly and giving one the idea that they were rather dilated at that point. He was kept in bed for a fortnight, and ordered a restricted diet according to Tufnell's plan, with for a few days five drops of tincture of digitalis three times a day; and during the fortnight he was also given regularly five grains of iodide of potassium three times a day. Mr. Dobson did not attach much importance to the drugs, except perhaps that the digitalis steadied the circulation; he believed it to be a drug, though suitable to this particular case at the outset, which requires much caution in its administration in aneurysms. Probably diet and quiet were most useful of all the medical treatment.

On May 13th digital compression was commenced by relays of students. Prior to its commencement a quarter of a grain of morphia was administered subcutaneously, and a like amount after about eight hours. The method of applying the compression was in all cases the same—viz., first ascertaining the dead weight that would control the pulsation (in this case about seven pounds); a graduated bag filled with shot to this weight was made. The compressors were two at a time, the duty of one being to place his index, middle, and ring fingers across the artery at the pubes; the weight was then placed over the middle finger, and thus with very little exertion on the part of the assistant and with but small discomfort to the patient the circulation was controlled. The second assistant applied his hand lightly to the aneurysm, and immediately informed his colleague when the circulation was not effectually controlled. This last point Mr. Dobson considered most important, as he had formerly found without this observation on the part of the second assistant that the person in charge of the artery above was inefficiently controlling it. By the small expenditure of force required when aided by the weight, two assistants could work satisfactorily for two hours, changing places every twenty or thirty minutes. After sixteen hours the pulsation in the left popliteal was thought to have ceased. On the next day, however, as there was slight pulsation, digital compression was continued, and after three hours and a half it was finally left off. On the 17th there was a slight thrill in the sac, but no pulsation; and on the 19th there was slight pulsation in the posterior tibial. No especial symptoms followed the compression, and the aneurysm was cured. After giving the patient some days' rest, digital compression of the right femoral in the groin was commenced in the same way, and the aneurysm of the right popliteal was cured after eleven hours and a half. The after-progress was satisfactory and without feature. This patient was seen recently, and he was continuing quite well.

Case 2. *Large Aneurysm of the Left Femoral at the Apex of Scarpa's Triangle.*—H. P——, aged sixty-three, a shoemaker, was admitted on Jan. 16th, 1885. He is an anæmic, flabby, delicate-looking man; never had syphilis. Four years ago he was kicked by a man in the region of the present swelling. There is a slight scar in the skin in this situation, but from careful inquiry the conclusion was arrived at that the blow had nothing to do with the aneurysm. The heart is sound, and no aneurysm was discovered elsewhere. The femoral is dilated in the groin, and pulsates forcibly. There is a swelling in Scarpa's triangle as large as an infant's head; he first noticed this about a month ago; it was then not larger than a hazel nut. There is not much pain, and no œdema of the limb. The swelling pulsates with marked distensile pulsation, and on auscultation there is a very decided bruit. The swelling is soft, and gives one the idea of its walls being tolerably thin; no arcus senilis; pulse 76. He was kept in bed, liberally fed, and had a mixture of iron and quinine for a week. On Jan. 23rd, at 10.45 A.M., digital compression, assisted by an 8 lb. weight, was commenced, a quarter of a grain of morphia having been previously given subcutaneously. The details were the same as in the former case, hot water bottles being placed in his bed, and the limb lightly wrapped in cotton-wool. 2.15 P.M.: The limb was blue and congested, with some amount of swelling generally. The patient was drowsy and pale, his pulse feeble, and he was sweating profusely. The tumour still pulsates. By 6.30 P.M. the congestion had passed off; it was probably occasioned by too much pressure, especially on the vein; the tumour is diminished in size; pulsation in the sac is not well-marked when pressure is taken off the artery. Compression was continued until 8.30 next morning (about twenty-one hours). There is still slight pulsation, but the sac feels firm and solid. On Jan. 27th, not being quite satisfied with the condition, Mr. Dobson ordered digital compression again for six hours, when the aneurysm was cured, and has remained so; the bruit had ceased entirely after four hours' compression on the second occasion. The tumour, which is now solid, is diminishing in size, and the superficial femoral above the tumour can be felt blocked. In the beginning of April this patient was again seen, and was remaining well.

Remarks by Mr. Dobson.—The points of interest in Case 1 are that both popliteals were affected at the same time; the combination of weight, indirectly applied through the fingers of a skilled assistant; and the immediate appreciation of any defect in the process by his colleague who had charge of the aneurysm. These may seem small matters, but it is the small matters that make up the difference between success and failure in digital compression. I regard Case 2 as particularly successful, because I considered the patient a bad subject for any operative interference, and from his general condition, as well as the local condition of the artery, I felt sure that had digital compression failed the Hunterian ligature would have laid him open to more than ordinary risks. The blueness and congestion of the limb were very ugly to look at, but they soon passed off when the pressure was moderated. In both cases I endeavoured to check entirely the blood stream through the aneurysm during the compression. It was found necessary to caution the assistants against over-exerting themselves, there being a natural tendency to employ more force than was absolutely necessary to check the blood stream, but the success of the cases was attributed in a great measure to their intelligence and zeal. The first aneurysm was thus cured by nineteen and a half hours' compression divided into two terms of sixteen hours and three hours and a half. The second aneurysm was cured by eleven hours and a half of continuous compression; and the third by about twenty-one hours on the first occasion and six hours on the second, with an interval of three days between the two; a result which may be considered favourable when compared with the statistics of instrumental compression. Spontaneous aneurysms of the lower extremity are surgically amongst the most interesting of the aneurysmal class; but judging from my own experience in the Bristol General Hospital I should say that in this part of the country at least they are not common. I have only admitted under my own care during the last ten years three cases of this disease in the lower limbs, and I can only call to mind another instance of this disease in which my colleagues have sought a consultation during the same period. I have, therefore, thought that a short history of the two cases might be of surgical interest, not only on account of the complete success of the treatment adopted, but also as illustrating certain important points in the history of such cases, as well as allowing me the opportunity of emphasising the importance of the minute attention to detail which is necessary to bring to a successful termination any such case. With reference to the first case which I have mentioned, sufficient time—viz., five years—has elapsed to be certain of the permanence of the cure.

LEICESTER INFIRMARY AND FEVER-HOUSE.

STRANGULATED FEMORAL HERNIA WITHOUT CONSTIPATION; OPERATION; DEATH; NECROPSY; REMARKS.

For the following case we are indebted to Mr. C. J. Bond, house-surgeon.

E. H——, a healthy woman, aged fifty-seven, has suffered from right femoral hernia for four years, and has never worn a truss. The hernia had been reducible up to Nov. 27th of last year, when during exertion the tumour suddenly increased in size; in a couple of hours the patient felt sharp pain in the swelling, and vomiting occurred. From this date (Nov. 27th) up to her admission on Jan. 7th, 1885, she suffered more or less from vomiting, which came on at irregular intervals, and is said to have "smelt very bad" on one occasion. The bowels were moved irregularly at intervals of two or three days. Sometimes there was diarrhœa, and the last motion was on Jan. 4th, three days before admission. Up to this time she had been getting up, and went to see a medical man on this day. On her admission on Jan. 7th she was in a state of semi-collapse, but was operated on immediately. The little knuckle of gut, though red, was not very dusky, nor apparently much inflamed, and in no way gangrenous. The stricture, which was tight, was divided, and the gut returned. No omentum was seen. The patient never rallied after the operation, and died in a few hours.

Necropsy, with remarks by Mr. Bond.—The portion of intestine was found lying close to the opening of the crural canal;

the mark left by the constricting band was very plain, and, what is especially noteworthy, did not involve the whole circumference of the intestine, but passed obliquely on one side within about half an inch of the mesentery, and on the other rather nearer this edge; thus not obliterating the whole calibre of the bowel, but leaving a narrow channel along the mesenteric border of the gut. It is this fact which, I think, throws light on the peculiarity of the symptoms; for here is a case of strangulated hernia in which the strangulation is so complete in a portion of the intestinal tube as to lead to perforation, and yet in which, owing to the obstruction having been partial only, the symptoms are spread over a period of six weeks, and the bowels are moved, though irregularly, throughout that time. Attention seems to have been diverted from the real cause of the symptoms by the fact that though the patient vomited she did not get appreciably worse, and by the absence of constipation. The standard works on surgery mention no exception to the rule of complete constipation in strangulated hernia—in fact, do not refer to cases of strangulation of portions only of the whole calibre of the small intestine; and the condition doubtless is not common. At the same time there are specimens showing it in several of the London museums—two in that of University College, described in the catalogue by Beck and Shattock; but no account is given of the symptoms before operation. It would thus seem well to remember that it is possible to have cases of strangulation of a knuckle of intestine of such severity as to lead to perforation, there being no constipation, the symptoms resembling those of a case of chronic partial obstruction of the whole tube. At the upper part of the site of the stricture at one spot there was an opening into the intestine, through which fæcal matter had, evidently just before death and since the operation, escaped into the peritoneum, and helped to bring about the fatal result; there was no general peritonitis. In The Lancet for March, 1882, I published some cases from which it seemed to me very probable that in cases of injury to the intestinal wall from extreme nipping, the perforation takes place from within outwards, and not from without inwards, commencing in ulceration and destruction of the mucous coat first, and, as in this case, nearly always at the site of the upper stricture, or that limiting the upper, full, dilated portion of intestine above the strangulated part. In this case it would also appear that the tight constricting band, though involving only a portion of the whole calibre of the gut, had by pressure caused not only ulceration of the mucous membrane at several points along its path, but at one point destruction of this and the muscular coats, leaving only the band itself, the thin peritoneum, and some plastic lymph to close the opening. As long as the knuckle of intestine remained *in situ* no escape occurred; but as soon as this band was divided, the adhesions broken down, and the intestine returned into the abdomen, fæcal matter rapidly escaped, though none was seen at the time of the operation, and the gut was for this reason returned instead of being left, with the stricture relieved, outside the abdomen, or an artificial anus being made.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Hæmaturia from Bilharzia Hæmatobia.—Experimental production of Chorea.

An ordinary meeting of this Society was held on the 26th inst., Dr. George Johnson, F.R.S., President, in the chair. The meeting was prolonged for half an hour in order to discuss the second paper.

Dr. Spencer Cobbold read a paper on cases of Hæmaturia due to Bilharzia. The author explained that the terms "endemic hæmaturia" and "Bilharzia disease" can no longer be regarded as synonymous, and insisted upon the necessity of separating the dysenteries and hæmaturias that are, and that are not, due to parasites. Any measures of prophylaxis, to be successful, must have for their basis an intimate knowledge of the genesis of the parasite, and to this end the author had made some experiments with very young specimens of Helix aliaria: these molluscs were subjected to the action of the swimming ciliated embryos; the latter, however, though constantly sticking to the snails, refused to penetrate their bodies. The living ciliated larvæ were next subjected to the action of certain drugs: alcohol, santonin, salt, &c. The embryos were found to be excessively sensitive to stimuli of all kinds. Thirteen cases of the disease were fully described. Post-mortem investigations have shown that the home of Bilharzia is the portal system, where the adult worms have been found in great numbers, including, however, but few females, and only a small proportion in sexual combination. The eggs accumulate within the chylopoietic branches of the portal vein, and also within certain systemic veins that anastomose with them. To the dispersion of the eggs nearly all the symptoms of the disease are due, and the intimate relation between the chylopoietic veins and the systemic veins supplying the genito-urinary passages is sufficient to explain why the kidneys, ureters, bladder, and rectum are all liable to become the seat of the disease. An outline of Sonsino's classification of the Bilharzia infarcts was given. The author considered the remarkable variations of the eggs of Bilharzia to have no pathological or clinical significance. The employment of medicated injections and "surgical treatment" were both condemned, and reliance was rather placed on good climatic conditions, general tonics, and other means, to aid the curative efforts of nature. Dr. Cobbold showed eleven specimens of the adult worm, six of the worm as it occurred in the human being and five in the ox. Dr. Sonsino had also sent him through the kindness of Sir Joseph Fayrer a specimen of Bilharzia crassa, which was a larger and stouter parasite, the eggs were different from B. hæmatobia, and had spines at both ends. He showed several other kinds of Bilharzia, some of very large size. Mounted preparations of a bladder which showed miliary infarcts in the left seminal vesicle were also exhibited. Some stones which had been removed by cystotomy had been sent to him by Dr. Kartulis; the eggs formed the nuclei of the calculi. Photographs and microscopic preparations illustrated the paper.—Dr. George Johnson said that the main point of contention was as to the effect of local treatment.—Dr. John Harley said that it was to be wished that we had completed the life history of the parasite, but he thought that no advance had been made. He referred to his original observations on the subject. He could not agree that improvement in the general health was necessary for the cure of the disease. Very healthy people took the disease, and large numbers of robust individuals suffered from it. Nephritic colic was sometimes observed as the result of the disease. Whereas no cure had been effected in Dr. Cobbold's cases, he had had one case under his care in which local treatment was attended with success. He spoke of the value of soluble drugs like iodide of potassium injected into the bladder; also of the use of the oil of the male fern. He had never recommended the use of perchloride of iron, and condemned anything like heroic treatment. His remarks were illustrated by reference to cases which had been under his care.—Dr. Cobbold, in reply, thought that cures of the disease might be mere delusions, for the parasite may exist for a long time without giving rise to symptoms. He was glad that there was so little divergence of opinion in regard to treatment. Reference was made to the observations of Mackie, in some of which the ova were found in the rectum and sigmoid flexure, but not in the bladder. The parasites did not enter the bladder through the urethra. The notion that the parasites were free in the bladder was an erroneous one. The "bedchamber" and principal seat of the parasites was the portal system, and Kartulis had counted no less than 300 specimens (and the number might be much greater) sexually combined in the portal vessels of one case.

Dr. Angel Money read a paper on the Experimental Production of Chorea and other results of Capillary Embolism. The experimental investigation of which this communication is the first contribution was begun in October, 1884. The animals used have been rabbits, guinea-pigs, cats, and dogs. The emboli found most suitable were arrowroot particles, granules of potato starch, and carmine. The particulate liquid was generally injected into the common carotid artery. Sometimes the injection was made towards the brain, but, as a rule, the liquid was injected towards the heart. It is exceedingly easy to produce embolism of the capillaries of the brain, but it is very difficult to get emboli into the capillaries of the upper part of the spinal cord without causing death by paralysis of respiration. The most important clinical observation which has come out of the experiments is the production of involuntary movements indistinguishable from those of chorea. These movements have not been accompanied by appreciable paralysis or spasm. The chorea of the animals experimented on never resulted from capillary embolism of the brain. In nearly every animal in which the brain was affected with capillary embolism some form of "uncontrollable" movement was present, allied, the author believes, in essential nature to chorea. The "chorea" of the animals experimented on was always the result of embolism of the capillaries of the spinal cord. The want of development of the pyramidal tracts in the animals under consideration possibly affords an explanation of the reason why chorea does not in them result from embolism of the brain proper. The author is of opinion that the reasons given for locating the lesion of most cases of chorea in the human subject in the brain are too powerful to be upset by experiments on animals so far removed from man as those experimented on by him. When the "chorea" of the animals experimented on was well marked, reflex action in the spinal cord was exaggerated. The suggestion is made that in the few cases of chorea in the human being where the reflexes are exaggerated, the spinal cord will be found to be the seat of the pathological condition. Rhythmical repetitions of one movement and also irregular succession of different movements have both been observed, so that experimental "chorea" both resembles and differs from the chorea of man and the ordinary chorea of dogs. Spinal paralysis has been observed as the result of the author's experiments, and also complete facial palsy. The respiration and cardiac action are variously affected by capillary embolism. The temperature appears to be always lowered, but it is difficult to eliminate the influence of the shock of the operation. Capillary embolism may give rise to any symptom of disease of the nervous system. As a rule, the capillary emboli gave rise to no pathological lesion recognisable by the microscope or naked eye. The view is supported that chorea is due to defective nutrition of the same kind as that which leads to paralysis, though in a less degree. This defective nutrition may be brought about by many causes, of which embolism is one. The relationship of chorea to involuntary movements generally was discussed. Suggestions were made for differentiating the varieties of chorea.—Dr. Hughlings Jackson thought the paper was one of great value. That irregular, involuntary movements of any kind had been produced by artificial embolism was a very important thing. That the movements were or were not like those of chorea in man was not the question of first importance, although one of great moment. We could in no circumstance expect to see abnormal movements in a dog's forelegs, like the elaborate movements of a child's arm in chorea; the dog was not capable of such movements. The fact that in human chorea the movements were very elaborate, was some evidence as to localisation—pointing to the morbid affection of some part of the nervous system "high up," where the nervous arrangements were very special and complex. Since 1864 Dr. Hughlings Jackson had held that the seats of the lesions in chorea were convolutions near the corpus striatum, at the same time, after Kirkes, suggesting that the lesion was often owing to plugging of small arteries; he had never undertaken to show that this process was the sole one productive of chorea. That some convolutions did represent movements was, since the experiments of Hitzig and Ferrier, certain. As the face was affected in chorea, it was clear that there was some lesion above the spinal cord; cases of hemichorea in which the face was affected were inexplicable on the view that the lesion was spinal only. Certainly cases of post-hemiplegic chorea and pre-hemiplegic chorea were inexplicable on that view; in these cases, indeed, cerebral lesions had been found (Weir Mitchell, Charcot, Raymond, and Demange). It might, however, be said that in ordinary chorea in man spinal lesions also were concerned; they had been found by Dickinson and Ross. Again, it had been proved by Legros, Chauveau, Carville, and Bert, that in a choreic dog the abnormal movements of its foreleg persist after section of the cord above the origin of the nerves for that limb. Dr. Hughlings Jackson had found the same. In the canine chorea of veterinarians the movements were rhythmical, and it did not follow that in this animal such comparatively simple movemements might not be capable of development from activity of spinal centres, whilst they might not be so in a higher animal, as in man much more elaborate movements were often seen. Albertoni, Franck, and Pitres affirmed that an epileptiform seizure started in a dog by faradaic irritation of some part of its motor cortical region, continued in spite of sudden removal of the part of the cortex excited. An objection often brought against the hypothesis of embolism and thrombosis was that these processes led to destruction of nervous elements. That was perfectly true; and it need not be said that from destroyed nerve tissue there could result no movements of any sort. But then it was equally true that with destructive lesions there sometimes occurred over-development of movements—e.g., post-hemiplegic chorea. It is certain, too, that epileptiform seizures occurred in some cases of local cerebral softening from thrombosis or embolism. A condition for repeated seizures was established. In these, and in most cases of chorea, everyone had two opposite motorial states to account for, some paralysis and some over-movement. Destruction of some nervous elements from embolism could only account for the paralysis in chorea; there must be on any hypothesis an over-activity of some other nervous elements to account for the co-existing over-movements. He reasserted that over-movements of some kind (post-hemiplegic chorea, athetosis, epileptiform seizures) do occur in cases where there are destructive cerebral lesions. Dr. Hughlings Jackson thought the researches of Dr. Dickinson (Med. Chir. Trans., vol. 59) went a long way towards proving the hypothesis of embolism and thrombosis as a cause of chorea. He said this with great respect, as Dr. Dickinson rejects that doctrine. Dr. Dickinson said the lesions in chorea were determined in position by the course of the arteries in the brain notably by the middle cerebral, which, as he stated, are the favourite routes of emboli. He wrote, "The first visible change would seem to be the injection or distension of the arteries, succeeded by extrusion of their contents to the irritation and injury of the surrounding tissues." Was not this like a description of embolism or thrombosis? He found also spots of sclerosis "degeneration of nervous elements;" the sclerosis was usually periarterial. Now, this sort of change, the sclerosis, a negative one, softening in miniature, could not cause movements of any kind. There must be another change, an opposite one, else there would not be the over-development of movements. Moreover, Tuckwell, Bastian, and Ross, had found plugging of arteries in some cases of chorea. Dr. Ross in his great work on Diseases of the Nervous System related a very important case, confirming Dr. Richardson's observations. Ross found plugging of anterior or antero-lateral arteries of the cord, and also necrotic spots in the corpora striata. Regardless of any hypothesis, Dr. Money's researches proved that in some way some involuntary movements are producible by embolism. It could scarcely be but that his work would be of great scientific and practical importance; it constituted a new starting point. Dr. Hughlings Jackson concluded by remarking that in chorea there was often a condition for embolism or thrombosis; that the movements were hemiplegic or double hemiplegic; that emboli most often did get into the middle cerebral artery which supplies the convolutions supposed to be morbidly affected in chorea, and that slight faradaic excitation of these convolutions did produce elaborate movements, although it was not yet proved that it set up a persistent condition for a quasi-spontaneous succession of different movements at different intervals as such as occurred in chorea.—Dr. Charlewood Turner contributed some observations from fatal cases of chorea in the child. Some large nervous cells taken from the third layer of cells at the fissure of Rolando were much swollen and distorted; these were large polar cells. The nuclei were obscured. All the cells of this layer were not affected. A paralytic condition of the motor nerve cells in this particular part of the brain, from which volitional impulses are transmitted to the muscles, might account for the phenomena of chorea. In chorea no properly arranged movements were possible. If the control of the highest centres were removed, then the emotional movements would be increased in activity; for it was probable that the movements of emotion were energised from other parts of the grey matter of the brain. Reference was made to the views of Dr. Hughlings Jackson on the alliances of incoördination with paralysis. Dr. Turner thought the embolic theory scarcely sufficed to explain the phenomena of chorea, for the effects of capillary embolism soon passed away. Where permanent destruction was caused as the result of embolism paralysis resulted.—Dr. Octavius Sturges spoke of the great value of the experimental investigation made by Dr. Money. He, however, thought there were clinical points in chorea which showed that chorea could not be due to structural lesions. A slight febrile attack or an acute specific fever, such as scarlatina or typhoid fever, would abolish chorea, and the chorea would not return so far as he knew on recovery from the acute specific fever. Then there were other points in the history of chorea which went against the embolic view. The sexes were so differently affected, and in a matter of race there was so much difference. Indians were but little affected. The movements observed in animals, though they were spoken of as chorea, did not appear to him to be of that nature. Again, emboli were absent in most cases of fatal chorea occurring in children. He questioned whether the movements observed by Dr. Angel Money ought to be called chorea.—Dr. **COBBOLD** drew attention to some observations made by Böllinger, Friedberger, and others of aneurysm in the horse, which was so frequent in horses more than seven years old. It was stated that 90 per cent. of such horses were affected with this "worm" aneurysm. The worm was called strongylus armatus. Various irregular nervous movements resulted from the introduction of these worms into the arterial circulation, into which they got from the aneurysms.—Dr. **JOHN HARLEY** said that he had shown that cryptopia could give rise to choreic movements. Narcein dissolved in glycerine and injected under the skin of small animals gave rise to lethargy and convulsions. The alkaloid was absorbed into the circulation and deposited in the tubules of the kidneys and produced a physical anuria which no doubt gave rise to the convulsions, which set in about three hours after the hypodermic injection. He asked whether there were any emboli in the kidneys in Dr. Money's experiments.—Dr. **BROADBENT** said that the paper required a great deal of careful reading, but it was plain that the whole investigation was one of immense value, and it opened the door to further investigations, which could not but be productive of great results. Speaking of human chorea, he thought age rather than race and sex was the most important factor. He had held that capillary embolism was one cause, but by no means the sole cause, of chorea. Dr. Money had shown that almost every symptom of nervous lesions could be caused by capillary embolism. The rhythmical movements in animals were not the equivalent of chorea in the child. Human chorea was distinctly a cerebral affection, as the cases of hemichorea also bore out. He had more than once seen hemichorea followed by paralysis and reappear as the palsy disappeared. He knew also that febrile affections caused chorea to disappear.—Dr. **ANGEL MONEY**, in reply, contended that he had not suggested that chorea was usually caused by embolism. His observations merely pointed to the conclusion that embolism was a probable cause in some cases. He considered that Dr. Sturges was not in harmony with clinical observation in believing that chorea was always due to one cause. Dr. Money's chief contention was that any symptom of disease of the nervous system could be caused by capillary embolism. Chorea was due to a defective nutrition of certain parts of the nervous system, and this defective nutrition might be brought about by many means, embolism among the number. He had stated in his paper that the reasons for locating the lesion in the brain in human chorea were irrefutable. In reply to Dr. Harley, he said that there were no emboli in the kidneys, and that the spontaneous movements came on immediately after the injection of the artificial emboli into the arterial circulation. He thanked Dr. Cobbold for the information given with regard to embolism in horses.

PATHOLOGICAL SOCIETY OF LONDON.

Varicella Gangrenosa.—Thrombosis of Veins from Gonorrhœa. Addison's Disease.—Atrophy of Adrenals.—Rodent Ulcer.—Secondary Glioma.—Calculus in both Ureters.

THE last ordinary meeting of the session was held on Tuesday, the 19th inst., Dr. J. S. Bristowe, F.R.S., President, in the chair. The subject of the relations of Addison's disease to the adrenal bodies was in the ascendant.

The report of the Morbid Growths Committee on Mr. Treves' cases of tumour of the soft palate was read by Mr. Shattock. The report stated that the first tumour was an alveolar sarcoma; the second tumour was a spheroidal-celled carcinoma, but not improbably it had commenced as an adenoma.

Dr. **PAYNE** read notes of a case of Varicella Gangrenosa, which occurred in a girl aged three years. An ulcerated eruption was seen on admission to the hospital, and varicella had been present a month before. At the autopsy there were signs of acute miliary tuberculosis; to his knowledge there was only one other post-mortem record, and this was by Dr. J. Abercombie; in this case tubercular disease, not so extensive, was also present. It might be a mere coincidence that tubercle and varicella gangrenosa should be associated, though it might possibly be a factor in the explanation of the occurrence of gangrene in such eruptions. He discussed the other possible relations of the two affections. The combination of the varicellar and tubercular poisoning, if not inducing the gangrene, might at all events have led to the fatal result of the two cases in question.—Mr. **BOWLBY** showed a drawing of a case of varicella gangrenosa made from the body of a male child aged ten months, who had had varicella fourteen days before he was first seen. There were altogether six gangrenous patches. The infant recovered and left the hospital; it died a day after in convulsions, but no necropsy could be obtained. A second case, that of a female child aged eight months, who had had doubtful varicella ten weeks before admission, was narrated. The vesicles became purulent and ulcerated, and some went on to a sloughy state. A fresh crop of vesicles came out whilst the patient was in hospital, but none of these went on to gangrene. The third case mentioned was that of a female infant aged eighteen months. The sores were much the same as in the other cases. No doubt a gangrenous condition might supervene on cutaneous eruptions which were not varicella, though they were vesicular, and possibly the second case was of this nature.—Dr. **RADCLIFFE CROCKER** had seen two fatal cases and some of an intermediate degree. The tubercular association of gangrenous ulceration was suggested by Dr. Barlow some time ago. In one of Dr. Crocker's fatal cases there was a strong tubercular history, and it was said that an elder brother died from tubercular peritonitis. In some cases of gangrenous eruption there was no distinct history of chicken-pox. The gangrenous condition did not always appear to come from the varicellar eruption itself, but in the skin which had not been the seat of the varicellar vesicles. There were, he thought, various grades of the affection; deep pustules sometimes formed and healed without any gangrene supervening. The gangrene sometimes appeared as the varicella was subsiding. In other cases, as in one of Mr. W. Haward's, the fourth day was the date of the onset of the gangrene. A septic change occurring in the secretion might explain some cases. Death from pyæmia was not unknown in connexion with these eruptions. Evidence of tubercle was not to be obtained in some of the cases. In his experience the eruption sometimes appeared to be benefited considerably by sulphocarbolate of soda administered internally.—Dr. **PAYNE**, in reply, had not been aware that Dr. Barlow had suggested that tubercle was an active agent in bringing about the gangrene of such cases as those in question, though he had some recollection of such a suggestion in connexion with vaccinia gangrenosa.

Mr. **BILTON POLLARD** showed a dissected specimen of the Pelvic Viscera and Veins of a case of Thrombosis consequent on Gonorrhœa. The patient was a woman aged nineteen, who had suffered from gonorrhœa for thirty-six days before death. The other symptoms present were pyrexia, the temperature ranging between 100° and 102°; some pain in the knee and fixation of the right hip-joint. The symptoms of disease of the hip-joint were at times equivocal. Death was due to embolism of the pulmonary arteries. The specimen showed thrombosis of the left common iliac vein, left internal iliac vein, and vaginal veins. There was no ulceration in the vagina. The cartilage of the femur and acetabulum of the right hip-joint was eroded, and the joint contained purulent material. No other joints were affected. Mr. Pollard thought the case remarkable in that so serious a set of conditions should complicate a case of gonorrhœa without giving rise to symptoms sufficient to call attention to the perilous state of the patient.

Dr. **SAUNDBY** showed the Spleen and Semilunar Ganglia of a case of Atrophy of the Suprarenal Capsules. The patient was a female aged eighteen. At the age of thirteen she was first seen, and it was noted that she had a somewhat Italian cast of countenance and complexion. She was treated afterwards for anæmia, amenorrhœa, and other disorders, but Addison's disease was not then suspected as the cause of her ailments. About August, 1884, there was pyrexia, and then the spleen was found to extend to the umbilicus, being much enlarged. An attack of faintness in January, 1885, was premonitory to a fatal seizure, from which she died comatose a few days later. All her life the urine had been dark and contained a large quantity of indican; a trace of hæmoglobin was found on one occasion. The heart was somewhat hypertrophied. Some pigment arranged in chains in the cortex of the kidneys was seen in sections of these organs. The adrenals were much atrophied; one weighed ten grains and the other eighteen grains. The spleen weighed sixty-six ounces. He referred to McMunn's spectroscopic researches, which seemed to lead to the inference that the function of the suprarenal bodies was to destroy the effete blood pigment. Other points of interest in the case were referred to. The father died at thirty-seven with an enlarged spleen and passed black urine all his life, and a brother had an enlarged spleen and many attacks of melanuria. Dr. Saundby commented on the three important elements of an enlargement of the spleen, of the dark-coloured urine, and of the occurrence of these symptoms in one of three members of the same family in which these symptoms coincided. In Greenhow's work mention was made of an enlargement of the spleen in two cases, but no stress was laid on it. Rosenstein, in the fifty-sixth volume of Virchow's *Archiv*, stated that he had found a large quantity of indican, ten times the normal quantity, in the urine of cases of Addison's disease.

Dr. Seymour Taylor read notes of some cases of Addison's Disease. The first was that of a female, single, aged thirty-five, who had all the signs well marked of Addison's disease. The pigmentation was typical. The viscera were healthy; the capsules were in the ordinary cheesy condition; the spleen was not enlarged. No tubercle was found in the other viscera; there was no pigment on the vagina; the labia minora were pigmented, especially about the nymphæ. Sections of the nymphæ were shown, which presented a great contrast between the external and internal surface. The pigment was seen in the rete mucosum and in the intercellular cement in the deeper layers of the epidermis. There were also many scattered pigment granules in the cutis vera. The second case presented the same changes in the nymphæ. Neither of the two women had been pregnant, and so the pigmentation could not have resulted from pressure on the veins.

Dr. Hadden read notes of a case of Atrophy of the Suprarenal Capsules with Addison's Disease. The patient was a single woman aged thirty. Vomiting was the first symptom, and began eight months before admission. The tongue and gums became pigmented. Pigmentation of the skin and mucous membranes was present on admission to hospital. The superficial reflexes were marked; the knee-jerk absent. Constant vomiting, attacks of fainting, headaches, and drowsiness were the main symptoms. Death took place suddenly three weeks after admission, just after an attack of vomiting. At the autopsy pigmentation of the vulva, skin around the anus, and upper end of the gullet were noticed. There was no tubercle anywhere; the adrenals were equal and distinctly small; the diminution was specially noticeable in thickness; the shape and colour were normal; the free edge was irregularly notched. The length of the left suprarenal was one inch and a half and its breadth three-quarters of an inch. The connective tissue around the capsules and sympathetic nerves was healthy. Microscopically, the suprarenal body showed much fibrous thickening of the investing capsule. There was a richly fibrous nucleated growth in the zona glomerulosa. Many of the cells were atrophied, and most were replaced by the newly formed tissue. In some parts the cell spaces were surrounded by dense fibrous tissue, and the spaces themselves were empty or contained atrophied cells. The nucleated growth passed inwards between the columns of cells in the zona fasciculata, separating them into islets. In many places the epithelial cells had undergone nuclear proliferation. The medulla was very scanty and difficult to distinguish. There were large areas of round cells, similar to those seen in the suprarenal body, in the semilunar ganglia. There was also a little granular pigment in the connective tissue. The nerve cells were probably healthy. The lymphatic glands were healthy. The state of the adrenals resulted from a chronic interstitial change, similar to that seen in cirrhosis of the liver. The lesion was identical with that of the thyroid gland in myxœdema. He regarded it as probable that no constant morbid change is essential for the production of either Addison's disease or myxœdema. The lesion must be a destructive one. Tizzoni's experiments were referred to as proving that in rabbits pigmentation of the skin occurred after destruction of the suprarenals. It was difficult to say that the change in the semilunar ganglia had any share in the production of the disease. Nevertheless, it was probable that the sympathetic nerves are at fault in Addison's disease. The rich supply of nerve fibres to the semilunar ganglia suggests that there is a relation between them and the sympathetic. Destructive disease of the adrenals must involve the nerve fibres which enter them. There may be a supplementary relation between the two, or the suprarenals may exert a controlling or moderating influence on the sympathetic.

Dr. Kingston Fowler showed the Adrenals and Semilunar Ganglia from a case of Addison's Disease, which occurred in a woman aged twenty-six who was under the care of Dr. Cayley at the Middlesex Hospital. The duration of the disease was three years. The illness began with an attack of vomiting, which lasted one week. These attacks became more frequent. The pigmentation was fairly marked. Syncope closed the scene. The adrenals were much atrophied. The right one was calcified and contained a caseous nodule in the centre. The left one was still more contracted. The nerves did not present any obvious changes. The case was doubtfully one of Addison's disease. He thought that Dr. Saundby's case was not an ordinary one of Addison's disease, and if there were any of the Addisonian element in it, it was probably mixed up with some other diathesis.

Dr. Samuel Wilks considered that the occurrence of atrophy of the adrenals supported Addison's original contention, which was to the effect that any destructive lesion could cause the symptoms of the disease. It was true that many cases of cancer, effusion of blood, and abscesses of the adrenals had been shown in which no symptoms of Addison's disease were present; but then he contended that both the adrenals were not destroyed by such conditions. The disease which could cause absolute destruction must be a slow integral change and probably of an inflammatory nature. In the early stages of such a change the organ might be enlarged, subsequently degeneration of a fibrous, calcareous or caseous or mixed kind would occur, whereby the organ might be totally destroyed. Such changes were to be seen in the liver and kidneys, which, however, being more vital organs, could not be totally destroyed without causing death. In the mamma and testis such changes could lead to the complete disappearance of the organs.—Dr. Hale White did not doubt that the ganglia in Dr. Hadden's case did not present an abnormal appearance. He thought we should not pay too much attention to the abnormal change. Addison's disease could occur without any change in the ganglia that could be recognised by histological examination.—Mr. Victor Horsley did not think the evidence supported the doctrine of disease of the sympathetic nerves as the cause of Addison's disease.—Dr. Bristowe thought the evidence so far adduced confirmed the original statement of Addison that the disease was caused by anything that destroys the adrenals completely. The view that Addison's disease was a tubercular disease of the capsules was not the correct one. He believed that the special function of the capsules was not a nervous one, though it was one which was essential to the well being of the economy. He conjectured that these bodies have certain special duties to perform in the way of removing waste products, or else as supplementary to other functions; and when these functions were disturbed, the organism suffered in some definite way which we clinically recognised as Addison's disease.—Dr. Wilks repeated that it was only possible to get total destruction of the bodies when there was an integral change in the organ itself. And he doubted whether any adventitious disease could cause complete destruction of both adrenals.—Dr. Saundby said the spleen was of a dark-purple colour, soft and pulpy. A large amount of pigment scattered amongst the cells was seen in microscopical sections. There was simply atrophy of the adrenals and no fibro-nucleated growth. He regarded it as a case of primary atrophy. The semilunar ganglia showed no special change. His own experience strongly supported the view which Dr. Hadden had advocated.

Dr. Thin gave an account of the sequel of a case of *Rodent Ulcer* fully described by him in 1879 in the Pathological Society's Transactions. The theory of the structure of rodent ulcer therein advocated was still maintained by him. The man since 1879 had been admitted into Middlesex

Hospital under the care of Mr. Morris, where he was in 1881. His death took place in September, 1884. The disease had spread from its original site on the scalp, when it was the size of a five-shilling-piece, until it had caused great destruction of the neck and side of the head. The distinctive and characteristic histological appearances were still to be observed in the borders of the large destructive ulcerating mass. The idea that a rodent ulcer becomes epitheliomatous was not borne out by Dr. Thin's case.

Mr. GEORGE LAWSON exhibited the drawings and post-mortem preparation of a case of Secondary Glioma. The patient, a little girl aged two years and two months, had the left eye removed by Mr. Lawson in December, 1883. In January, 1884, he removed the right eye, as it was distended with a gliomatous tumour, causing great pain. From both these operations the child rapidly recovered, and from each experienced great relief. In the following month, February, the child was admitted into the Middlesex Hospital with a recurrence of the tumour in the left orbit. The tumour continued to grow until it not only protruded beyond the orbit but covered the whole of one side of the face, overlapping the nose, the mouth, and the lower jaw. The child was kept free from pain by repeated small doses of morphia, and she took her food well. She died on August 3rd, 1884. There were no brain symptoms until a few days before her death, when she had several epileptic convulsions. At the post-mortem examination the whole of the left side of the face was occupied by a large tumour, slightly ulcerated in places. There were no secondary deposits in the organs of the chest or abdomen. In the fibres of the right deltoid muscle there was a lobulated mass, having the same appearance as the orbital growth. On removing the calvaria the dura mater was seen to be covered at irregular intervals with deposits of glioma varying in size from a pea to a penny. On cutting through the membranes, the convolutions were seen somewhat flattened and the meningeal veins distended. On removing the brain a tumour about the size of a small orange was seen occupying the pituitary fossa and neighbouring portions of the sphenoid bone, apparently having originally sprung from one or both optic foramina.

Mr. CULLINGWORTH (Manchester) showed specimens of Impaction of a Large Calculus in each Ureter, which were taken from a woman aged thirty who had had a swelling in the right side for two years; the symptoms dated back ten months, when a distinct attack of pain in the back and right side was first experienced, and during which attack there was much pus in the urine. This attack lasted two weeks, and similar attacks came on from time to time. Pyuria was observed to the extent of half the quantity of urine passed. An operation with a view of removing the diseased kidney or relieving the pyo-nephrosis was undertaken by the abdominal section. The right ureter was found to be obstructed immediately above its opening into the bladder. The ureter was opened, and a calculus was removed which was the size of a walnut. Three days afterwards symptoms of uræmia set in and the patient died. At the autopsy the left kidney was also found to be full of abscesses, the ureter was dilated and contained a calculus at its lower end. Had the existence of disease in both urinary tracts been suspected, he should not have operated in the way he had done. The pus came from the left kidney, for the right ureter was perfectly impervious as the result of the impaction of the stone.

The following card specimens were shown:—

Dr. Goodhart: (1) Viscera from a case of Phosphorus Poisoning; (2) Specimens of Leprosy of Hand and Larynx for Dr. Beaven Rake of Trinidad.

Dr. Burnet: Primary Melanotic Sarcoma of Liver.

Mr. Makins: Primary Sarcoma of Tibia.

Dr. Sharkey: (1) Impaction of a Coin in the Œsophagus for twenty months; (2) Aneurysm of Heart; (3) Multiple Epithelial Growths in the Œsophagus.

Mr. Poland: Sections of Epithelial Growths in the Viscera after Epithelioma of the Tongue.

Dr. Chaffey: (1) Multiple Sarcoma in a child; (2) Lymphosarcoma of Bladder.

Mr. Hutchinson, Jun.: Epitheliomata of Hand.

Mr. Arbuthnot Lane: (1) Bony Process from Humerus; (2) Displacement of Foot from Fracture of Bones of Leg; (3) Fracture of Sternum.

Dr. Gilbert Barling: (1) Round-celled Sarcoma of Peroneus Longus; (2) Alveolar Sarcoma of Triceps.

Dr. Hale White: (1) Perforating Tubercular Ulcer of Intestine; (2) Grain of Corn causing Typhlitis and Intestinal Strangulation.

Dr. C. Turner: Aneurysm of Aorta communicating with the Superior Vena Cava.

Mr. Shattock: Hernia into the Fossa Duodeno-jejunalis in a child.

Dr. Hebb: Melanotic Sarcoma of Spleen, &c.

Dr. Dawtrey Drewitt: Persistent Branchial Fissure in a child (living specimen).

Mr. F. B. Jessett: Lower Jaw removed by operation for Cancer (recent specimen).

Mr. A. E. Barker: Gangrene of Finger Ends, probably due to syphilitic arteritis.

Mr. Bland Sutton: Difficult Labour in a rickety monkey.

CLINICAL SOCIETY OF LONDON.

Report of the Committee on Spina Bifida.—Successful Œsophagotomy.—Raynaud's Disease.—Surgical Treatment of Tumour of the Bladder.

THE last meeting of the session of this Society was held on May 22nd, Mr. Thomas Bryant, F.R.C.S., President, in the chair.

The report of the Committee on Spina Bifida was read by Mr. R. W. PARKER. The subject was divided into two parts: (1) the pathological anatomy of spina bifida; (2) its treatment.

1. *Pathological Anatomy.*—The term "spina bifida" was used to define certain congenital malformations of the vertebral canal with protrusion of some of its contents in the form of a fluid tumour. With very rare exceptions the malformation affected the neural arches of the vertebræ, and the tumour projected posteriorly; in rare cases, however, the bodies of the vertebræ were involved, the tumour in such cases protruded anteriorly into the thorax, abdomen, or pelvis between the lateral halves of the bodies affected. The museum specimens were discussed under the following headings:—(1) Position of tumour; (2) size and configuration of the sac; (3) coverings of sac; (4) disposition of the meninges within the tumour; (5) size and configuration of the deficiency in the neural arches; (6) disposition of the spinal cord and nerves; (7) unusual variations; (8) the process of cure. The result tended to show that the specimens fell under three divisions:—(1) Protrusion of membranes only (simple meningocele); (2) protrusion of membranes together with the spinal cord and its appertaining nerves (meningo-myelocele); and (3) protrusion of the membranes together with the spinal cord, the central canal of which was dilated so as to form the sac cavity, the innermost lining being constituted by the expanded and atrophied substance of the cord (syringo-myelocele). The committee stated that the meningo-myelocele was by far the most frequent, while simple meningocele came next, and syringo-myelocele last. As a typical example of the common kind, a specimen now in the College of Surgeons was quoted. This was a case of lumbo-sacral spina bifida, the size of a Tangerine orange, sessile, but constricted slightly at the point of attachment. The tumour presented normal skin for a short distance round its base, but the central portion consisted of a thin translucent membrane; along its vertical axis the tumour was slightly furrowed, this furrow corresponding to the attachment of the cord to the inner surface of the sac wall. The spinal cord ran almost horizontally across the upper part of the sac, and then became incorporated with the sac wall, from which also the lowest nerves arose; they then passed across the sac to gain the intervertebral foramina, from which they issued normally. The anterior and posterior roots of the nerves were separated from each other by an exaggerated ligamentum denticulatum. A careful dissection was often necessary in order to distinguish simple meningocele from syringo-myelocele. Mention was made of several variations; among these the division of the sac into smaller loculi, and the occurrence of bony outgrowths across the vertebral canal button-holing the spinal cord, were the most remarkable. Careful microscopic examination of the sac wall in a typical case of meningo-myelocele had disclosed the continuation of the central nervous system within its median vertical portion, the integrity of the central canal of the cord within this part, and the absence of true skin over it. It further displayed the absence of any meningeal cavities behind the incorporated portion of the spinal cord; it was clear, therefore

in the first place, that the nerve roots, which traverse the sac, arise from this intramural portion of the central nervous system, and that all expressions of descriptive pathological anatomy which imply a *distribution of the nerves to the sac wall* are a reversal of facts. Even more important than this, the histology of the sac wall in a typical case, by demonstrating the integrity of the central canal of the included portion of the cord, showed beyond dispute that the neural furrow does not remain unclosed in spina bifida, nor after having been closed is it subsequently distended by dropsy and ruptured. The absence of true skin from the central portion of the sac wall was next adverted to. The membrane implied that the mesoblastic basis of the true skin, and the structures lying in subjacent connexion with it, had not been developed. The presence of the cord in the sac wall offered no difficulty of explanation when its epiblastic origin was remembered. The theory therefore which best explained the pathological anatomy of spina bifida was that which assumed a primary defect of development of the mesoblast from which the structures closing in the vertebral furrow were developed.

2. *Clinical Course and Treatment of Spina Bifida.*--In order to form a correct estimate of the value of treatment by the injection of Dr. Morton's iodo-glycerine solution, the committee had endeavoured to ascertain as far as possible the natural history of the deformity when untreated, and had prepared tables of cases treated in various manners for purposes of comparison. As regarded the natural history of the deformity, the Registrar-General's report for 1882 showed 649 deaths from spina bifida in England and Wales, of which 612 died under one year of age. The committee held that, though a certain number of these deaths were due to local causes—rupture of the sac, draining away of the cerebro-spinal fluid, and subsequent septic meningitis—yet in a large proportion of cases death ensued from the marasmus and general defective nutrition so frequently associated with the deformity, and which could not be remedied by any local or other treatment. The tables next dealt with treatment by injection with simple solutions of iodine, and showed a considerable amount of success. Then ligature of the sac was considered, and here again good results seemed to have been obtained. Excision likewise had a considerable proportion of success. The plan of repeated tapping and pressure gave the least successful results of any. The injection of Morton's fluid, according to the committee's tables, showed a percentage success of between fifty and sixty. The high mortality was thought to be largely due to the treatment having been adopted in unsuitable cases on account of its simplicity and supposed safety. In spite of the favourable results of ligature and excision of the tumour as shown in the tables, the committee felt themselves compelled to report against these methods of treatment. There was reason to think that the published cases might be misleading, owing to some cases of failures not being recorded, while all the successes, being regarded as surgical triumphs, were almost certain to have been recorded. Moreover, it seemed probable that a careful selection of cases had been made. The committee therefore advocated the plan of treatment by injection, and preferably by the injection of Morton's fluid. The report was signed by Mr. Howard Marsh, Mr. A. Pearce Gould, Mr. H. H. Clutton, and Mr. R. W. Parker.

A large collection of drawings, illustrating the usual forms, as well as the most noticeable variations, of spina bifida was exhibited, and the committee especially acknowledged the help which Mr. Shattock had rendered them.

The President said that the report contained a collection of information which could be found nowhere else. He ventured to say that many previous notions would have to be given up when the report became public property.

Mr. George Lawson read the report of a case in which he had performed successfully Œsophagotomy for the removal of a plate with three false teeth, which had been accidentally swallowed and was impacted in the œsophagus. The patient, a milkwoman, aged fifty-five, was admitted into Middlesex Hospital on Jan. 14th, 1885, having about half an hour previously swallowed a vulcanite plate with three artificial teeth. Mr. Lawson endeavoured, without success, to remove the foreign body with a pair of long curved œsophagus forceps. An incision about three inches in length along the lower prominent border of the sterno-mastoid muscle was made; the sterno-mastoid and the omo-hyoid with the carotid sheath were drawn outwards, whilst his colleague, Mr. Gould, drew the trachea in the opposite direction, and with his fingers on the right side of the neck pressed the œsophagus towards the incision. The œsophagus was now visible, and the plate could be easily felt with the fingers. A vertical incision was then made in the œsophagus on to the plate, and after some difficulty the plate was removed by dividing it with the bone forceps. No sutures were put into the œsophagus. The superficial wound was then partially closed with sutures and covered with boracic lint charpie, over which was placed carbolic gauze and oil-silk. The patient was ordered to be fed with nutrient enemas and Slinger's nutrient meat suppositories. On the following morning the wound was dressed, and there was found to be a very free discharge of saliva and mucus through it. On the 19th, the fifth day after the operation, some redness appeared around the wound, and this increased for two or three days. This was followed by an offensive discharge, with some sloughs of cellular tissue. On the 20th, the seventh day after the operation, as much of the fluid taken by the mouth continued to escape by the wound, Mr. Lawson introduced an œsophagus tube with a funnel-shaped extremity, which projected about six inches from the mouth. This was kept in, and through it the patient was regularly fed. The tube was worn until February 8th, when, as the wound in the œsophagus was apparently closed, it was removed. During this period the tube was changed about every four or five days for purposes of cleanliness. On February 22nd the external wound was healed, and the patient since then has been able to take her food as usual. She has left the hospital, and is now quite well.—Mr. Lediard (Carlisle) contributed some notes on a case of œsophagotomy. The patient was admitted into the Cumberland Infirmary with a tooth-plate in the œsophagus, which had become dislodged from the mouth during sleep some twenty-four hours previously. There was pain on swallowing and emphysema of the neck. Various attempts prior and subsequent to admission failed to remove the plate, which was believed to rest somewhere behind the thyroid cartilage. Œsophagotomy was performed, but nothing was found in the pharynx or cervical portion of the œsophagus; it was believed that during manipulation on the table the plate may have been unconsciously moved from its resting-place, as the mucous membrane of the œsophagus behind the cricoid cartilage was somewhat bruised. The wound healed well. The plate was passed per anum on the nineteenth day, and the patient went home quite well, having been in hospital a month. The plate measured 1½ in. by ¾ in., and had sharp points and a hook at one end.—Mr. T. Bryant said that no doubt the employment of the tube was a useful form of practice, but he thought that soft rubber tubes, like those used by Mr. Charters Symonds, would be an improvement on the hard tubes. Dr. Lediard's case taught us that we should not be in too great a hurry to interfere in such cases. He knew of the case of a man who passed a large plate with teeth eight days after the plate was swallowed. Sutures should not be put into the œsophagus where there was ulceration.

Dr. Colcott Fox read notes on two cases of Raynaud's Disease. A woman, aged forty-one, of extremely nervous temperament, dated the commencement of the disorder from ten years back, but though this was the period when her attention was attracted by pain, it is probable that she suffered from slight attacks for some years previously. In the earlier stages all her fingers continually went "like white wax." This condition of recurrent local syncope gradually gave place to local asphyxia, and the feet became involved. The fingers gradually lapsed into a state of chronic asphyxia, which was intensified by frequent attacks of more severity, often leading to "blood blisters and ulceration." The nutrition of the phalanges has suffered greatly, so that her hands are crippled, the fingers are fusiform in shape, livid, shiny, and withered, the nails variously distorted, and the end phalanges much atrophied and almost immovable. The nose and ears are affected to some extent on exposure. Cold and nerve shocks are ready exciting influences. The second case, that of a man aged fifty-one, was of considerable interest, from the fact that, like one of Raynaud's cases, he suffered from diabetes. His hands were not deformed, but he had suffered for several years from "dead fingers." He sought Dr. Fox's advice for symmetrical gangrenous patches on the skin, which recurred, and later for an attack of asphyxia of one great toe and lower third of the inner side of the leg, and then it was found that he had been attacked in a similar manner, though more severely, in the other toe, and on another occasion "blood blisters" had formed beneath the end of his toes. Dr. Fox concluded his paper by giving a reference to some cases which have been recorded as scleroderma of the extremities. A woman with the latter disease was shown to illustrate the difference between it and Raynaud's symmetrical gangrene of the extremities.—Dr. **BERNARD O'CONNOR** referred to a case of symmetrical gangrene associated with intra-thoracic tumour which he had shown during the last session at the Pathological Society.—Mr. **HARRISON CRIPPS** was inclined to look upon the gangrene of the second case as due to the diabetes. He considered that the pathology of Raynaud's disease might be regarded as midway between that of a frost-bite which was due to local influences and that of senile gangrene, which was almost solely due to constitutional causes. Mention was made of a severe case of widely distributed gangrene; the gangrene affected those parts which were at the very periphery of the circulation.—Dr. **BARLOW** asked to be allowed to supplement his former paper published in the Transactions of the Society by an account of some subsequent observations of the cases therein recorded. He wished to say something of the important question of therapeutics. He spoke of the use of the constant current in two of the cases. The first case alluded to was that of the man aged forty-two, who first suffered from severe paroxysmal attacks which had gradually become chronic, in which the chief symptoms were pain, coldness, and blueness, followed by tingling. In the autumn of 1883 the treatment was begun. At first one pole down the spine and another on the extremity was the method used as advocated by Raynaud. Later on he used with better results two poles to the asphyxiating part. This was done with the aid of a bath of salt water or by "painting" the part with both poles, which was the simplest and best method. Twenty minutes a day was the time devoted to the treatment, which lasted from August to April, and was followed by most decided benefit, which had been permanent. Shampooing was also advised to be continued, and had been practised before the galvanism, with but little success however. Acute paroxysmal attacks he had also treated by means of the constant current. In August, 1884, he had under his care the case of a girl in whom the asphyxia appeared in the hands and feet, lasted about two hours, and generally came on about 9 A.M. or 5 P.M. There was intense pain, and the feet became quite black to about two inches above the ankle. Drawings of this condition were exhibited. This case, which was treated by repeatedly reversing the current, of the strength of about twenty cells, gave decided results, for during some of the attacks but one foot was treated, and this foot recovered whilst the other remained black as long as in an ordinary attack. Nitrite of amyl was used, but had no influence on the local asphyxia, although the physiological effects were produced. In some cases the use of the constant current locally at the commencement of an attack effectually prevented its development. He suggested that the constant current and vigorous shampooing would prove beneficial in Dr. Fox's first case. He thought the action of the galvanism was simply that of a local stimulus to the circulation.—Dr. **COLCOTT FOX**, in reply, said in his cases the most severe pain was experienced as the attack was passing off. He did not think the gangrene was due to the diabetes in his second case, which had all the characters of Raynaud's disease.

Mr. **WILLIAM ANDERSON** read notes of a case of Papilloma of the Bladder. The patient, aged fifty-three, was admitted into St. Thomas's Hospital on August 9th, 1884, with symptoms of vesical tumour of twelve years' duration. The first indication of the disease was an attack of apparently spontaneous hæmaturia in 1872. After the third attack the relapses appeared about four times yearly. The hæmorrhage was for a long time the only symptom, and nothing confirmatory could be educed by investigation of the urine or by vesical examination, except a peculiarly localised tenderness in the region of the trigone on contact with a sound. In June, 1884, a vesical catarrh became superadded. On Aug. 14th the *boutonnière* operation was performed, and a soft flocculent growth was found occupying the region of the trigone, extending upwards for about one inch and a half from the internal meatus, and one inch on either side of the median line. The mass was removed by means of forceps, some hæmorrhage resulting. The progress of the case was satisfactory, and on Sept. 10th, twenty-seven days after the operation, the patient was discharged well, except for a minute perineal fistula and a trace of blood in the urine. He is still in good health. The points of interest in the case were the extremely slow evolution of the tumour, twelve years, and the absence of conclusive evidence of the nature of the disease before the digital exploration of the bladder. Under such circumstances any operation determined upon could only be exploratory in the first instance, but the patient probably owed his life to the surgical intervention. Theoretically it seems probable that relapse would take place sooner or later in a rather large proportion of cases considering the difficulty that must frequently arise in making sure of the complete removal of every portion of the tumour. Bearing in mind also the very slow development of the primary growth in many instances, it might be expected that the signs of recurrence would occasionally be deferred until a very late period. Out of thirty-eight cases in which the nature of the tumour was sufficiently indicated in the report, there are four instances of undoubted and four of probable recurrence, all within a year of the operation. Complete relief is noted in one case for five years up to the date of record; in one for four years; in five for two years; and in four for periods ranging between twelve and fifteen months. In nineteen other cases no signs of recurrence had appeared at the time of the report, but the observations had been limited to a term of less than twelve months. There are thus as yet only eleven cases out of thirty-eight in which is registered an immunity of one year and over, against eight cases in which relapse is noted as certain or probable.

Mr. **BERNARD PITTS** read notes of a case of Tumour of the Bladder. The patient, aged forty-three, was admitted to St. Thomas's Hospital on September 10th, 1884, suffering from some hæmorrhage from the bladder. He had a blanched and debilitated appearance, and stated that he had been passing blood with his urine for more than two years, and that of late the hæmorrhage had considerably increased in quantity. He had never suffered pain, but had been troubled of late with irritability of the bladder. The urine was offensive, deep red in colour, and contained much clot; microscopical examination showed traces of villi. A perineal exploratory operation was performed on Sept. 15th, and a large pedunculated tumour discovered on the right side, just below the orifice of the ureter. With serrated forceps portions of the softer part of the growth were broken off, but the wire of a strong écraseur was subsequently passed round the pedicle and the whole of the tumour thus removed. The pedicle was about one inch long, and of the thickness of a finger. A soft tube was left in the wound, and removed on the fourth day. The patient made a quick recovery, and on October 7th was passing all his urine the right way. He rapidly regained health, and has had no trace of further hæmorrhage up to the present time. The tumour, on microscopical examination, proved to be a fimbriated papilloma with the usual structure. Some remarks were made on the diagnosis of the case, which depended rather on the prominence of the hæmorrhage as a symptom than on the microscopical evidences in the urine. The probe-pointed gorget was tried but abandoned, and the dilatation of the neck of the bladder was made with an ordinary director as a guide for the finger. There was a good deal of bleeding during the manipulation with the forceps, and the operation would have been less prolonged if the écraseur had been used in the first instance. It was not, however, until portions of the growth had been removed that the extent of the pedicle was discovered. The prognosis in this case was a very favourable one, for by using the écraseur the pedicle was cut off quite close to the wall of the bladder, and the rest of the vesical surface was examined by the finger and found to be healthy.—Mr. R. J. **GODLEE** considered that it was justifiable to make an incision into the bladder in cases which must inevitably be fatal. He referred to such cases in which it was impossible to remove the whole growth, but the patient's life might be prolonged, and certainly their existence rendered more tolerable, by incision into the bladder with removal of as much of the malignant growth as was possible with safety. Professor **HUMPHRY** said, on invitation from the President, that his was the first case of exploration of the bladder that had been done in this country. He had heard that the boy was quite well two or three years after the operation. He had been much struck by the long period of cessation of hæmorrhage in cases of villous tumour of the bladder. He first became aware of this fact by a study of the specimens in the museum of St. George's Hospital. He could not interpret this fact. The multiple character of the growths was one reason why they were so difficult to cure radically.

Mr. T. **BRYANT**, in bringing the business of the session to a close, said that he considered that the great function of the Society was to discuss papers; and he thought it should not encourage the reading of long papers. The encouragement of full debating powers was all-important in a clinical society, for such debates served to show some fallacy or to elucidate new facts in the most telling manner.

The following specimens were exhibited:—

Mr. Jessett: A case of Plastic Operation for Epithelioma of Lower Lip.

Dr. Colcott Fox: Two cases of Raynaud's Disease.

Dr. de Havilland Hall: A case of (?) Rheumatoid Arthritis, with nodules on the head and clavicle, probably of syphilitic origin.

Dr. Hale White and Mr. Arbuthnot Lane: A patient with a Cervical Rib.

Dr. A. T. Myers: A case of Raynaud's Disease in a boy aged twelve years, in which the ears were affected, and there was Paroxysmal Hæmoglobinuria. The blood showed signs of disintegration of its red discs.

Dr. Stephen Mackenzie: A Remarkable Case of Nævoid Condition of Scalp, having a configuration very like the cerebral convolutions.

Mr. R. W. Parker: Sacro-coccygeal Meningocele.

Mr. Arbuthnot Lane: Fracture of both Superior Cornua of the Thyroid Cartilage.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society on March 6th,

Mr. **BRUCE CLARKE** showed a boy aged nine, who was convalescent from a Compound Starred Fracture of the Occipital Bone, together with a Linear Fracture of the Frontal Bone. Tetanus with emprosthotonos set in on the thirteenth day after the accident. Also a case of Union after Fracture of the Lower Epiphysis of the Humerus in a boy, and a successful case of operation for Strangulated Inguinal Hernia.

Dr. **THOROWGOOD** read notes of two cases of Peritoneal Abscess following attacks of enteric fever. Case 1 was that of a little girl aged ten years, seen with Dr. Eyre of Forest-hill. The patient's illness commenced about Dec. 2nd with symptoms of true peritonitis; typhoid spots subsequently appeared. Two days after return of temperature to normal a swelling appeared at the umbilicus, which, on being punctured, discharged a large quantity of foul-smelling pus. A drainage-tube was inserted, and beef-tea, tonics, and brandy were given, and, notwithstanding congestion of the base of the right lung, the wound was quite healed by Jan. 17th, and the patient made a good recovery. Case 2 was that of a woman aged thirty, who was admitted into the West London Hospital on Oct. 14th, 1884. The attack commenced on Sept. 27th with rigors, and was followed by vomiting and diarrhœa. Temperature on admission 100·4°; pulse 132. The patient lay on her back with her knees drawn up, and complained of much abdominal pain. On Oct. 17th the right side of the abdomen was very tender, and two typhoid spots were observed. Pea-soup motions; diarrhœa moderate. On the 21st an abscess was opened underneath the jaw, and healthy pus flowed out. The patient seemed to be doing well. On Nov. 2nd her temperature was 101°, pulse 132. A troublesome cough came on suddenly, followed by a copious expectoration of pus mixed with blood. There was dulness, with crepitant râles, at right base. On Nov. 6th the abdomen was noticed to be swollen and distinct fluctuation was felt; abundant purulent expectoration; pulse 150, temperature 101·5°; fluctuation in abdomen became scarcely perceptible after the copious expectoration of pus. Exhaustion set in, and, notwithstanding stimulating treatment and diet, the patient died on Jan. 26th. The source of the pus was the question which presented itself in this case. Suppuration of mediastinal glands was suggested, but there had been no difficulty in swallowing nor any noticeable dulness about either posterior or anterior mediastinum. The fluid in the peritoneal cavity appeared thick and similar to that expectorated. This, with the persistent crepitant râles at the extreme base of the right lung, gave support to the opinion that the pus came from an abscess below the diaphragm. The patient's previous health had been excellent. Nothing was noticed in relation to the liver. The post-mortem examination by Mr. Percy Dunn showed that a large abscess had formed in a sac quite apart and shut off from the intestines on the right side, and had worked its way upwards, perforating the diaphragm on both sides, ultimately finding its way into the bronchial tubes.—Dr. **TRAVERS** thought that in the absence of internal symptoms the diagnosis of typhoid fever on the strength of one spot was hazardous.—Dr. **BENNETT** said that though he had seen many undoubted cases of typhoid without spots, he had never seen a case where the spots did not class it as one of typhoid.—Dr. **THOROWGOOD** said the spot in his case was a typical one, and appeared about the time when the eruption was to be expected (second week); at the same time he was not prepared to say positively what the case was, nor was he enabled to say what the starting-point of the abscess was. No evidence of cicatrisation was found in the intestines.

Dr. **HERRINGHAM** showed a child aged three years and a half, in whom Hemiplegia had come on fourteen months ago. There was at that time palsy of the left arm and leg, and of the lower facial muscles of the left side, with almost complete palsy of the third nerve on the opposite side. Rhythmical tremors of the left side, increased by exertion, began even before the palsy was noticed, and continued ever since. The right third nerve had now almost recovered, but contraction and rigidity had set in on the left side, and were increasing. The child was in good health, and growing fast; no loss of mental power; never any optic neuritis; nor any history of syphilis or rheumatism. Heart normal. Iodide of potassium, arsenic, and tonics had had no effect. The diagnosis was a lesion in the right crus cerebri.—Dr. **BENNETT** said he saw this case some months ago, and was one of those who diagnosed the case as one of chorea. He did so again to-night, and his prognosis was favourable.—Dr. **THOROWGOOD** said that all along his opinion had been in favour of a slight hæmorrhage into the right crus, probably from thrombosis.—Mr. **LAWRANCE**, the President, said the movements seemed rather convulsive than choreic in nature.—Mr. **THOMPSON** asked whether the gentlemen who diagnosed the case as one of chorea were aware that complete hemiplegia existed on the right side, and that no improvement had taken place.—Dr. **HERRINGHAM** said, in reply, that no one who had watched the case had ever thought it to be chorea, nor could he conceive of anyone doing so, unless they understood by chorea "anything that shakes"; here the movements were rhythmic, in chorea they are distinctly not so; again, in no case of chorea of which he had heard had paralysis of the eye, or rigidity, or paralysis without wasting, occurred as here. As to the possibility of the presence of a tumour, he thought the lapse of a year had put it out of the question, as the tendency of cerebral tumours was to a fatal result. Eyesight had been normal all along; and there was no trace of heart mischief.

HARVEIAN SOCIETY OF LONDON.

AT the meeting on May 21st, the President, Dr. T. Morton, in the chair,

Dr. F. H. **CHAMPNEYS** read a paper on Certain Points in the Diagnosis of Cervical Stenosis. The author described briefly the anatomy and physiology of the cervix uteri; its cavity, its orifices, its secretion. As regards the os internum, it was pointed out that this orifice really belongs to the uterine body, and reasons were given for thinking that its size is variable in the same individual, and that it is not rigid, but undergoes spontaneous dilatation, being under the dominion of uterine polarity. He then discussed the diagnosis of stenosis, and showed that no certain inference could be drawn from difficulty in introducing the sound, because it could not be guaranteed that the sound was passed exactly in the calibre of the canal (though this could be assured in the case of the os externum), and because it might catch in a fold of mucous membrane. The diagnosis could, however, be made if difficulty in withdrawing the sound were experienced, because the instrument then travels of necessity in the right path. The paper concluded with notes of sixteen cases of cervical stenosis observed at St. George's Hospital.—The President, Dr. John Phillips, and Dr. A. Routh took part in the discussion. In answer to questions from various speakers, Dr. **CHAMPNEYS** expressed his disapproval of the operation for incision of the os internum on the grounds of the risk to life which it involved. Vaginal examinations of virgins should be avoided as a rule. Nevertheless where necessity demanded an examination, the fact of virginity should not be allowed to stand as an obstacle to the patient's chance of recovery. This should specially be borne in mind in connexion with dysmenorrhœa, which in the author's opinion often laid the foundation of serious pelvic disease.

Mr. H. E. **Juler** offered some remarks on the Use of the Ophthalmoscope in the Practice of Medicine. Dealing first with the methods of ophthalmoscopic investigation, the author described the three modes of examination known as the direct method, the indirect method, and the shadow test. Among the ocular affections which constantly recurred in ordinary medical practice, and for the safe diagnosis of which the ophthalmoscope was necessary, Mr. Juler referred to albuminuric retinitis, optic neuritis, retinal hæmorrhage, atrophy, tobacco amaurosis, and faulty refraction. The subject was illustrated by numerous diagrams, and by the use of artificial models of the eye. The more recent forms of ophthalmoscope were also exhibited, and their use practically demonstrated.—Dr. **Sansom** referred to the use of the ophthalmoscope in children's practice. With a little care and patience it was possible to examine the eyes of most, if not of all, children. Great assistance in matters of diagnosis could thus be obtained. Thanks to this help, he had frequently been able to recognise the existence of hypermetropia, of cerebral tumour, and of renal disease. The extended employment of the ophthalmoscope could not be too warmly advocated.—Dr. Alderson, Dr. Sydney Phillips, and Dr. Culver James also took part in the discussion.

The next meeting of the Society was announced for October 15th, 1885.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

At a meeting of this Society on April 8th, Norman Chevers, M.D., C.I.E., President, in the chair,

Dr. G. B. **Longstaff** read a paper on the Seasonal Prevalence of Continued Fevers in London. The author referred to the well-known decrease in the mortality from "fever" in recent years. This decrease, he stated, was mainly under the heads of typhus and simple continued fever; the mortality from enteric fever in London had remained comparatively stationary for the last ten years. Since 1869 no fewer than 4374 deaths had been attributed to simple continued fever in London. Following the method of Messrs. Buchan and Mitchell, the author had constructed a diagram showing the seasonal prevalence of the three forms of fever in London. The data made use of were the admissions to the London Fever Hospital, the admissions to the hospitals of the Metropolitan Asylums Board, and the weekly deaths in London since 1869. The results obtained from these various sources were in the main concordant. Enteric fever yielded a well-marked curve; the disease was least prevalent in late spring and early summer, most prevalent in the autumn. The curve of scarlatina was very similar to that of enteric fever. The small numbers available in the case of typhus did not give such well-marked curves, but such as they were, they were very different from those of enteric fever. The mortality and the admissions to hospital from typhus were at a minimum in July, August, or September; from this minimum they increased to an autumn maximum in October, or more usually in November; they were generally excessive throughout the winter; and another maximum, commonly higher than that in the autumn, occurred in January or February. The fall might be sudden in March, or more gradual, and as late as May. Simple continued fever appeared to be even less influenced by season than typhus; the imperfect curve yielded by it, contrary to expectation, showed no autumn maximum like that of enteric fever. Like typhus, simple continued fever showed a maximum in January or February and a minimum in August or September. The author of the paper considered that the deaths still so frequently assigned to simple continued fever were really due to some other cause, and suggested general tuberculosis, septicæmia, and pneumonia. The figures brought forward showed that the hospitals of the Metropolitan Asylums Board dealt with an increasing proportion of the cases of infectious disease in London; but this increase was steadiest and most marked in the case of scarlatina. In 1884 the proportion of deaths in the hospitals of the Board to the total deaths of the metropolis was 11 per cent. for enteric fever, 19 per cent. for typhus, and 16 per cent. for scarlatina.

Dr. **Thorne Thorne** exhibited some Plans of Isolation Hospitals which had just been issued by the authority of the Local Government Board, and which are designed to meet the requirements of small and sparsely populated districts in such a manner as to secure the best available separation, both of diseases and sexes, without the need for erecting separate pavilions. One of the plans showed how, under one roof, four beds might be placed so as to secure this end. Special arrangements were also made by which nurses could be provided with bedrooms in the same building without any chance of their apartments becoming infected with ward air. This plan is eminently adapted for securing to small towns of some 4000 inhabitants or less, or to public institutions, the maximum accommodation at the smallest cost. The other plan provided twelve beds instead of four, all under the same roof, but having no aerial communication with each other. The pavilion is not only adapted to towns of some 10,000 inhabitants, but it should always be provided as one of the pavilions where two or more are to be erected, its advantages being considerable where only one or two cases of a disease are under treatment, and also for the purposes of isolating doubtful or special cases.

CAMBRIDGE MEDICAL SOCIETY.

At a meeting of this Society held on April 10th,

Dr. **Grove** (St. Ives) related a case of Recovery after Severe Injury to the Head with Symptoms of Fractured Base. He was summoned at 6.30, on November 3rd, to the wife of a farmer who had met with an accident. She was forty years old, and was always healthy and temperate. She had returned home an hour previously from marketing, and had driven the pony carriage round to the yard, but fell in getting out. She was found with her head lying on the stone step in a pool of blood, which was running out of the right ear; she was insensible, and vomited soon after being removed into the house. When seen she was almost unconscious, but answered in monosyllables when spoken to loudly. The right meatus was filled with blood, which trickled out. She was placed in bed and ice applied to the head. There was no sign of injury to the scalp, the pupils answered sluggishly to light, and the pulse was slow, about 60. The next day she was more conscious, her face was flushed, and the pulse 84; she had vomited several times during the night. The right side of the face was swollen and bruised, and she complained of pain in the head; blood mixed with serum was flowing from the ear. The head was shaved, ice applied, and five grains of calomel were given. The third day she was better, slept more quietly, pulse 96, bowels relieved. On the fourth day, on lifting the eyelid of the right eye, blood was seen freely effused under the conjunctiva, and the day after there was evidently some paralysis of the right side of the face, with diplopia and indistinct vision with right eye, loss of sensation on that side of the face, and complete deafness with the right ear; any movement of the head caused great pain. She was fed on milk for about a month, and the bowels kept well open. The improvement was gradual, and in six weeks she was able to walk into another room. Her condition about four months after the accident was as follows: she is quite deaf with the right ear; the taste is impaired on the right side of the tongue; and the sensation on the right side of the head and face is diminished; the sight also of the right eye is not so good as the left, but there is no diplopia now. Dr. Grove was of opinion that the injury was caused by a direct blow in front of the right ear. The subsequent symptoms were very grave; the severe hæmorrhage from the internal ear and the paralysis, indicating injury to the fifth and seventh nerves, pointed to fracture, probably, through the petrous portion of the temporal bone.

Dr. **Earle** (Melbourn) exhibited the Temporal Bone of a Suicide with Bullet Wounds. In February, 1884, he was sent for to see a man who was said to have committed suicide, and he found that he had shot himself in the right ear. The external ear was slightly swollen, and there was some hæmorrhage, but besides this there was little to be noticed. A bullet could be felt with the probe, deep in the ear, but could not be extracted. He was then insensible, but he partly regained consciousness during the next few days. On the seventh day there was copious discharge from the left eye, and on the tenth day the right eye also became involved, and there was ulceration of the cornea of the left, which ultimately collapsed. There was also slight facial paralysis. On the fifteenth day he died, and a post-mortem examination revealed the presence of two bullets (a fact that had previously been suspected, as two chambers of the revolver were found empty). One bullet was found embedded in the mastoid process of the temporal bone, the other was found at the junction of the squamous and petrous portions of the temporal bone with the great wing of the sphenoid. The inner table of the skull was not pierced, but raised up, and over this the dura mater and pia mater were blackened to about the size of a sixpence; above this there was an abscess in the cerebral substance containing about a drachm of pus. It seemed remarkable that the man could have discharged two chambers of his revolver, with the results already related, with such unerring aim as not to injure the external ear, particularly as the absence of any blackening about the orifice of the auditory canal would seem to indicate that the pistol could not have been held very close. Further, that the bullets did so little damage as experiments with the rest of the cartridges proved that, at the distance of a yard, a bullet would go clean through a three-quarter inch deal board, and even at ten yards would be very deeply embedded.

Dr. Earle also showed a specimen of Aneurysm of the Arch of the Aorta, which he had removed from a middle-aged man who died suddenly. He had been a patient at Addenbrooke's Hospital under Mr. Laurence Humphry with symptoms indicating a tumour pressing on the œsophagus, but there were no definite physical signs. The aneurysm was in the third part of the arch of the aorta, and had ruptured into the œsophagus by a small ragged orifice.

Dr. Bradbury exhibited a specimen of Sarcoma of Ovaries, and read the case of a woman, aged thirty-eight, single, from whom the growth was removed. Her condition when admitted into the medical wards on March 7th, 1885, was as follows: the patient was thin and had rather the "ovarian expression," the abdomen measured thirty-five inches at the umbilicus, not uniformly distended but larger on the right side, where a hard swelling could be felt, it was dull to percussion; elsewhere percussion was resonant except in flanks. The lower part of the chest was dull to percussion on both sides, with feeble breathing, more especially on the right side. Urine 1025, no albumen. The ascites and effusion into the pleura increased and the legs began to swell; on March 22nd, there being much dyspnœa, the right pleural cavity was tapped, and 104 ounces of serous fluid drawn off, with temporary relief. The patient died on March 25th. The post-mortem examination showed much ascites, and in the right iliac region was found a large irregularly nodulated hard tumour pushing the intestines aside, and pressing the uterus downwards and to the left side. It was not adherent to surrounding parts, and was evidently growing in the right ovary. The left ovary was the seat of a similar tumour, only much smaller. The uterus was healthy. The peritoneum, especially that covering the under surface of the diaphragm, and the mesentery were studded with hard flattened nodules of small size; similar nodules were found covering the left pleura and lung, and there was much clear fluid in both pleural cavities. A microscopic examination of the ovarian tumours and secondary nodules showed that beneath the outer white glistening capsule was a zone of varying thickness, corresponding apparently to the tunica albuginea of the normal ovary, consisting of lamellæ formed by fasciculi of large spindle-shaped cells. From this zone septa descended into the bulk of the tumour, dividing it into larger and smaller lobules, and finally became lost by blending with the deeper substance. The lobules were good examples of the mixed-celled sarcoma, and some contained remains apparently of small Graafian follicles. All the secondary growths examined proved to be mixed-celled sarcomata. A direct connexion between the pleural and peritoneal growths was seen in the diaphragm, where clusters of sarcoma cells stretched along the lymph spaces between the tendons and muscle bundles and connected the serous sacs.

Vaccination Grant.—Dr. James Tily of Chiswick has received the Government grant for efficient vaccination.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

Thursday, May 21st.

Sir H. Acland, President, in the Chair.

The Council went into committee for the further consideration of the recommendations of the Branch Councils. The debate was resumed by

Mr. Simon, who said that in adopting the proposal of Dr. Banks yesterday the idea of the Council was that the second alternative should be adopted by the student, and that before entering on his professional course he should pass an examination in mechanics, elementary physics, chemistry, and biology. The promoters of the amendment, however, appeared to think that four years should be spent at a recognised medical school. His own view was that as much liberty should be allowed to the student as possible. Could it be gravely asserted that if a man spent six months as an assistant house-surgeon in a good provincial hospital like those of Bradford and Sheffield, or at a lying-in hospital, the time so spent should not be included in the curriculum? The English proposal left room for alternatives of that kind. If too much pressure was put on the student in favour of medical schools, the result might be that the number of students would be altogether out of proportion to the opportunities for practice. Thus several dressers might gather round one patient, and there were stories of two dressers having to attend to one leg between them. The Council ought to call in to the aid of medical instruction as many hospitals and infirmaries as possible. Many of the members of the Council were also members of recognised medical schools, and they should be on their guard against ειδωλον. If a committee of curriers were considering the question of armouring ships they would probably come to the conclusion that there was nothing like leather. He objected to tyrannical regulations. If it were possible to do with an examination without any curriculum at all, he should be in favour of it. The English proposal was as far as it was desirable to go, and he hoped that the amendment would not be pressed.

Mr. Teale agreed that it was undesirable to rivet the fetters too closely. Each branch of the kingdom should be at liberty to adopt the method it thought most convenient.

Dr. Pettigrew deprecated the system of pupilage alike for the student, the profession, and the public. A busy practitioner could hardly be expected to give much time to teaching. In a hospital it would be better for the student to have only one case well demonstrated than a great number of cases treated in a general way. He did not think three winter and two summer sessions sufficient. Many instances had arisen of the evils produced by unqualified assistants, and they were calculated to bring the profession into disrepute. He was therefore in favour of Dr. Haldane's amendment.

Dr. Humphry protested against Scotland and Ireland laying upon England a yoke which she was unable to bear. Scotch students might be willing to listen to a hundred lectures on surgery in six months, and to profit by them; but it was otherwise with English students. The details and processes of education should to a great extent be left to the licensing bodies themselves. To the Scotch and Irish mind a pupil was an unqualified practitioner, but in truth he was not a practitioner at all. In many cases it was a good thing for a young lad from school to be placed under a judicious medical practitioner, who could look after not only his studies but his morals. He had himself commenced his studies with a strong dislike to everything connected with the profession, but he was placed under a superior medical practitioner in a town where there was a hospital, and where his abhorrence was converted into an ardent love for his studies. Subsequently he had three years in a medical school, and then had the good fortune to become surgeon to a hospital. At hospitals like those at Brighton and Norwich the student was under first-rate practitioners, and it would be monstrous to exclude work done at such places from the curriculum.

Dr. Storrar admitted that no better instruction could be given than at hospitals like that at Norwich, and under a good medical practitioner; but the Council's recommendations were not mandatory, and the bodies might interpret them with some latitude. If, however, the four years' study were not clearly specified, students might devise means for evading the regulations, and parents might do the same from motives of economy. The College of Surgeons and the College of Physicians might be justified in allowing a year to be passed at the hospital at Exeter or Leeds, but that was different from laying down as a principle that four years might mean something less than it really did.

Dr. HAUGHTON thought that the debate was the most important of any in which he had taken part since he had been on the Council. In Ireland there were thirty-two county infirmaries with from forty to sixty beds, and there were also fever hospitals. Many of the most distinguished physicians and surgeons in Ireland had attained high rank after attending those infirmaries, which were recognised by the College of Surgeons. The time spent in a county infirmary was regarded as equal to half the time in a metropolitan hospital; and it was the same at Trinity College if the surgeon at the infirmary was considered competent by medical professors. But Ireland would never recognise apprenticeship to a private practitioner, who could not possibly teach mechanics, physics, chemistry, zoology, and botany. No doubt an exceptional result of private study had been produced in the case of Dr. Humphry, but notwithstanding his imperfect education (laughter), Dr. Humphry would have risen still higher if he had been trained on the Scotch or Irish system (much laughter). He (Dr. Haughton) strongly objected to giving the student permission to spend a year and a half out of the four years as an apprentice.

Dr. HUMPHRY reminded Dr. Haughton that the resolution only referred to recognised schools, not to infirmaries or hospitals.

Dr. SCOTT ORR said he did not think there should be one rule for England and another for Scotland and Ireland.

Dr. DUNCAN said he objected to the English proposal, because it was practically undoing what was done on the previous day. It was absurd to require five years and not to require any more study. He had opposed the five years, not because he objected to that time, but because he thought the motion premature. After all, the Scotch proposal only required thirty-three months out of the sixty to be spent at a medical school, leaving twenty-seven months to be spent elsewhere. That was a most liberal arrangement; indeed, he thought far too liberal. With such an arrangement the provincial hospitals would have plenty of applicants for their offices. With regard to attendance on lectures, he had no doubt that the present movement for a teaching university for London was for the purpose of extending professorial teaching and providing more lectures. English students were as desirous as Scotch students to have more lectures, as he could state from his own experience. At present the lectures on midwifery in London were very meagre. Some courses did not consist of more than twenty lectures, which he considered a mere farce. Some of the students who had attended such lectures in an eminent school had told him that they wished they had never gone to them, as they were not worth hearing.

Dr. Duncan's speech was interrupted by the announcement that the hour had arrived which the Council had appointed for the further consideration of the case of Ebenezer Bryceson. Strangers then withdrew, and the case was considered in private.

On the readmission of the public it was announced that the Council had agreed to the following resolutions:—(*a*) "That Ebenezer Bryceson is judged, after due inquiry, to have been guilty of infamous conduct in a professional respect, in that he has produced to the Royal College of Surgeons of England forged certificates of professional study." (*b*) "That the General Medical Council, though it adjudges Ebenezer Bryceson guilty of infamous conduct in a professional respect, does not, under all the circumstances, now direct his name to be erased from the Medical Register."

Sir H. PITMAN moved: "That the solicitor of the General Medical Council be authorised to take the opinion of such counsel as he may think fit as to the readiest mode of carrying into effect the penal clauses of the Medical Act."

The motion was agreed to without discussion.

Dr. STRUTHERS suggested that, as all the educational business could not be completed at the remaining sittings of the Council, it would be better to take the other business first.

The Council then adjourned.

FRIDAY, MAY 22ND.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

The further consideration of the motion and amendment with regard to Recommendation 21 first occupied the attention of the Council. By permission of the Council the amendment was altered to read as follows: "At least four winter and three summer sessions shall be passed at a school or schools recognised by any of the licensing bodies mentioned in Schedule A of the Medical Act."

Dr. DUNCAN, continuing, said that upon coming to London he increased the number of lectures on midwifery from a nominal forty, which was a practical thirty, to between seventy and eighty. The lectures were given every day in the week, and it was the largest midwifery class in England. If he gave 100 or 120 lectures, he was sure students would attend regularly. When the question of midwifery was under consideration about six or eight years ago, two of the most eminent medical lecturers on midwifery in London wrote clamorously for an increase from forty to 100 in the number of lectures. Dr. Humphry's opinion therefore, as to the capacities of English medical students, was not held by some of the eminent midwifery lecturers. The recent movement for a teaching university in London was doubtless partly the outcome of a desire for introducing into London what might be called the Scotch system of education. It would be a very great pity, he thought, if the extension of the curriculum for five years was not utilised in that way. He was satisfied that the apprenticeship system in England and Scotland was only valuable under peculiar conditions. If that system was ever restored, it must be in that modified collegiate method which was practised with great advantage in Edinburgh and Dublin. He should therefore support Dr. Haldane's amendment.

Mr. MACNAMARA said he was surprised to hear the observation of Dr. Humphry recommending the Council to legislate for Scotland and Ireland, and not to attempt to touch England. He wished to say that sitting round the Council table of his College were some of the most distinguished men in medicine, surgery, and midwifery (including Dr. Kidd), all of whom were engaged in teaching, and most of whom had commenced as grinders; and seeing that such men had suggested and enforced the plan of education now pursued in Dublin, it was only natural that the Irish representatives should bring it before the Medical Council. They were assembled not to legislate for one division of the kingdom or another, but to make general laws applicable to all. Dr. Humphry had told them of his own experience in connexion with his residence with a provincial practitioner. He (Mr. Macnamara) might be permitted to narrate some experience of a different kind. On the previous evening he had met a distinguished officer in the army; he had been educated according to the Irish system, and attributed to that method the high position which he had attained. He was an apprentice of his (Mr. Macnamara's), and he said: "After I left you I went to provincial practice as an assistant, and I was so disgusted with it that I resolved to enter Her Majesty's service. The gentleman had a large practice. I used to go round and prescribe for patients, and when I came back I often found my prescriptions altered because the medicines were too expensive. The pupils made up the prescriptions, and that was the experience they had to enable them to present themselves for examination. The practitioner himself taught them nothing because he did not know anything to teach. The students spent part of their time in compounding prescriptions, and the rest of the time in smoking." They could never consent to anything of that kind in Ireland or Scotland. Their duty was to legislate for the United Kingdom, and to provide one system of education applicable to every portion of Her Majesty's dominions. What the College of Surgeons in Ireland did was to allow twelve months in a provincial hospital to count as six months in a metropolitan one; but if a man spent his whole lifetime in a provincial hospital he must still spend four winter and three summer sessions in a recognised medical school. In three towns in Ireland there were not only hospitals but admirable schools, where the student could carry on his studies as well as in Dublin.

Dr. HUMPHRY desired to remind Mr. Macnamara that he had never suggested separate legislation for one portion of the kingdom. The resolution he had supported was that at least one winter and two summer sessions should be passed at some recognised school, but that if either of the three divisions of the kingdom desired to extend that period it should be at liberty to do so.

Mr. Marshall, in supporting Dr. Haldane's amendment, said that, having gone on the line of extending the period of study, the Council would be inconsistent if it did not endeavour to utilise the additional period in the best possible way. It was the business of the Council to take care that students had a good knowledge of the science on which medicine was founded. When men left the schools they rarely returned to them, and it was only the education received in the schools over which the Council could exercise any control. They could not control practitioners, but they could insist on a high-class scientific education in the medical schools of the country.

Dr. Struthers considered that the point at issue was the most important of those that had been brought before the Council. The three years' English system had always been looked upon in Scotland in connexion with the drugging and apprenticeship system, which was the worst feature of practice in England. No doubt the student might learn something from a general practitioner, but would he learn as much as he could at a medical school? The practitioner was a busy man, constantly in the saddle or in his brougham, and the pupil was chiefly occupied in making up prescriptions, learning really nothing of what was inside the body. It was impossible to combine a trade and a profession. According to the English system, a medical man might be tempted to say, "I do not think my patient needs anything, but if I prescribe a dose, it will be 2*s*. 6*d*. or 5*s*. in my pocket." Such a system was degrading. The medical man in Scotland was a gentleman occupying the same position as the clergyman and the lawyer. Was that the case in the provinces in England? ("Yes.") According to his experience it was not.

Mr. Simon: As much as in any other division of the kingdom.

Dr. Struthers said that apprenticeship was part and parcel of the English system. It had been said that the Scotch graduates were not fitted to be good assistants. The fact was that they were too good to be assistants. They would make bad assistants in the same way that they would make bad grocers' assistants, and in that sense the worse they were the better. The student must begin with anatomy and physiology, and then proceed to pathology, and have some clinical training besides, before he was fit to visit patients. A man might have a thousand midwifery cases and yet be an unqualified man. The fourth year was really the best year for the student, and they could not afford to lose sight of him during that year.

Mr. Simon said that no doubt amusing stories could be told with reference to general practitioners; and if it contributed to Dr. Struthers' happiness to believe that Scotch graduates were too good to be assistants to English practitioners, they could have no objection to it. But the question was not one of medical apprenticeships. The main question was whether public provincial hospitals should be recognised, or whether there should be a narrow limitation of medical education to a comparatively small number of specially privileged schools. They had no right to say that a medical practice could not be learned in a provincial hospital. His own bias would naturally be in favour of a London medical school, but he objected to a despotic law such as some members of the Council desired to impose. The English proposal was that a certain minimum period should be spent in a particular way; but if any of the licensing authorities desired to increase the period they were at liberty to do so.

Dr. Chambers said he was anxious to extend the curriculum, in order to afford an opportunity to candidates for holding residentships or other medical appointments.

Dr. Quain said it was true that a man might get but little good from his residence with a general practitioner, but he might get still less good at a medical school. He believed that Dr. Struthers greatly undervalued the training to be obtained under a general practitioner. As to the value of lectures, with great respect to Dr. Duncan, he did not think very highly of them. He himself took honours at the University of London in midwifery, and never attended a lecture in his life. He could say as much against that kind of education as Dr. Struthers had said against apprenticeship. They wanted to get at results. Let the examinations be duly visited and made complete, and they wanted nothing more. As to whether there should be three or four sessions, he was ashamed to discuss such questions. Medical education was of a most unpractical character. A few weeks ago he visited a patient, and on asking the medical attendant how she was, he replied, "Temperature 100·5°," but he could tell him nothing about the state of the bowels or the urine.

Dr. Watson said that what they had to consider was the difference between the education given at a medical school and that obtained in the condition of pupilage. He objected to maintain a condition of matters which to his mind was exceedingly bad. To decide upon the briefer period, and to leave it open to the universities and corporations to determine what they would demand, would be an unfortunate step for the Council to take. After all the steps that had been taken by the Council, there was one thing especially needed to elevate the condition of the profession—viz., that the practitioner should cease to be a druggist. As to the education likely to be received under a country practitioner, he considered that it would be worse than nugatory. He had been told by a friend who had been a pupil of a general practitioner in London (now dead), who had a number of ladies of distinction under his care, that sometimes when the medicines were being dispensed he would say, "Lady So-and-so is too well; put a little antimony in her mixture." Nothing of that kind would be likely to occur in connexion with the education given in a public school. Dr. Humphry had given a true picture of his own early experience, but it should be remembered that since that time the profession had undergone a great change. The present days were far removed from the time when one of the duties of a practitioner's assistant was to go body-snatching.

The President, before putting the amendment, said he had heard with some regret more than one humorous description of things that had occurred in former days in connexion with the medical profession. Anyone of his own age could confirm the truth of the descriptions; but he was quite sure some of the most hard-working, wise, and honourable Englishmen were to be found among country practitioners. He had, from accidental circumstances, a considerable knowledge of them in various parts of England, and if he were asked for a typical man of a practical, serious, and benevolent character, he would undertake to produce him from among the general practitioners of the kingdom. He also knew something of the difference between the circumstances of a Scotch and an English practitioner. It was an error to suppose that it was possible for all country practitioners in England to rely upon the quality of the drugs or the skill of the druggist in remote districts. In many cases the medicines could not be properly dispensed if they did not do the work themselves.

The amendment was then put, and carried by a majority of 16 against 5, three members not voting.

On its being put as a substantive motion,

Dr. Lyons moved as an amendment: "That at least four winter and three summer sessions be passed at any school and hospital recognised by any of the licensing bodies mentioned in the Medical Act." This, however, was not seconded, and it accordingly fell to the ground. The motion was then put and carried.

The next recommendation considered was No. 22: "No teaching or licensing body should insist on the student taking more than one course of lectures on any one subject."

Sir H. Pitman said it was the opinion of the English Branch Council that the recommendation should be omitted altogether; but perhaps it would save time to accept the suggestion of the Scotch Branch Council, seeing that anatomy and clinical instruction were exempted from the general rule laid down.

Dr. Haldane moved, in behalf of the Scotch Branch Council, that the recommendation should read as follows: "No teaching or licensing body should insist on the student taking on any one subject more than one course of lectures, which should include practical instruction, but practical anatomy and clinical instruction should be exempted from this recommendation." In Scotland, he said, a course of lectures generally included 100, besides 50 as an additional practical course. That number was too great, and involved considerable additional expense to the student. Some of the 100 lectures should be devoted to practical teaching, except in the case of practical anatomy and clinical instruction. A single course, however, in practical anatomy and clinical instruction was not sufficient.

Dr. Haughton said he was willing to accept the Scotch proposal if "surgery" were included in the exemptions.

Dr. Haldane accepted Dr. Haughton's suggestion, and the motion was modified accordingly.

Mr. Simon thought that the matter should be left to the discretion of the schools. He agreed with the suggestion of the English Branch Council that the recommendation be omitted, and he would move as an amendment that that course be adopted.

Mr. MARSHALL seconded the amendment, which was carried by a majority of 11 against 9; and it was also carried as a substantive motion.

Sir H. PITMAN moved that Recommendation 23 read thus:—"The following are the subjects without a sufficient knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered:—(1) Chemistry, including the principles of the science, and the details which bear on the study of medicine, and the rudiments of heat, light, and electricity; (2) anatomy; (3) physiology; (4) materia medica and pharmacy; (5) pathology; (6) medicine, including medical anatomy, clinical medicine, and therapeutics; (7) surgery, including surgical anatomy and clinical surgery; (8) midwifery, including diseases peculiar to women and to new-born children; (9) theory and practice of vaccination; (10) forensic medicine."

Mr. SIMON seconded the resolution, which was then put and carried.

Dr. HALDANE moved: "That hygiene be added—viz., No. 11."

Dr. HERON WATSON seconded the motion, which was agreed to.

Dr. SCOTT ORR moved: "That mental disease be added as a separate subject—viz., No. 12." He remarked that numbers of practitioners were quite at sea with regard to insanity, although the most appalling consequences might result from their ignorance.

Dr. DUNCAN seconded the motion, which was supported by Dr. BANKS.

Dr. HAUGHTON, referring to the recent trials in Dublin, said on that occasion many witnesses were called, some to swear that the accused was insane, and others that he was shamming. Such a state of things was a scandal to the medical profession.

Dr. HERON WATSON approved of clinical education in mental disease.

Dr. PETTIGREW considered that the subject might come in as a department of medicine.

Dr. STRUTHERS moved as an amendment, and Mr. SIMON seconded: "That the following footnote be inserted:—It is understood that insanity, diseases of the skin, and other subjects on which special instruction may be given, are included in the above enumeration."

Dr. LYONS said that a Bill having reference to mental disease was now in Parliament, and it would not do for the Council to treat the subject as a mere subsidiary matter.

By permission of the Council, Dr. STRUTHERS then withdrew his amendment, and the original resolution was agreed to.

The Council then determined to dispense with Recommendations 24, 25, and 26.

Sir H. PITMAN moved, and Mr. SIMON seconded, that Recommendation 27, chap. 5, read as follows:—"The professional examinations shall be so framed as to secure that the knowledge of every practitioner whose name appears in the Medical Register has been tested in all the subjects of professional education which the Council deems essential—namely, (1) chemistry, including the principles of the science and the details which bear on the study of medicine, and the rudiments of heat, light, and electricity; (2) anatomy; (3) physiology; (4) materia medica and pharmacy; (5) pathology; (6) medicine, including medical anatomy, clinical medicine, and therapeutics; (7) surgery, including surgical anatomy and clinical surgery; (8) midwifery, including diseases peculiar to women and to new-born children; (9) theory and practice of vaccination; (10) forensic medicine; (11) hygiene; (12) mental disease."

The motion was agreed to.

The recommendations that had been passed in committee were now adopted by the Council.

The following report by the Dental Committee was, on the motion of Sir H. PITMAN, seconded by Dr. H. WATSON, received and ordered to be entered on the Minutes:—

"The name of Charles Russell Turner, [illegible] having been [illegible] the Dental Committee [illegible] December [illegible] Edinburgh [illegible]"

The Council then rose for the day.

SATURDAY, MAY 23RD.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

The Council reassembled at one o'clock.

Sir H. PITMAN, as chairman of the Business Committee, asked the President what course the Council desired to take in respect to the offence committed by Mr. Ebenezer Bryceson under Sections 39 and 40 of the Medical Act.

The PRESIDENT said that that question of course referred to the entry of the Bachelor of Medicine degree of Cambridge upon the Register. He could not say what course the Council was likely to take with reference to that, but he thought it his duty to apply to the solicitor of the Council to ascertain what, if anything, in his judgment should be done. As soon as his reply was received, it would be laid before the Council; but of course that could not be done during the present sitting.

The Council then resolved itself into committee for the purpose of the further consideration of the reports by the Branch Councils in regard to the General Council's recommendations as to the age at which students should be licensed to practise, and on professional education and examination.

Clause 29: "The professional examinations should be arranged in two divisions, the first division to embrace the more elementary subjects. The first division may be completed at or before the close of the second year of professional study, but the second division not till the expiration of two years after the passing of the first division, nor before the completion of the fourth year of study. The examinations, and the subjects included in each, should be such, and in such order, as may ensure, as far as possible, a due continuity and sequence of study."

Sir H. PITMAN moved the adoption of the English Branch Council's recommendation, although he could not quite agree with it. "The candidate should not be admitted to the second examination till he has passed the first, and he should not be admitted to the third examination till at least twenty-one months after passing the second, nor until the completion of forty-five months of medical study." His own feeling was that the final clause of the existing recommendation was the only one that the Council should adhere to. It seemed to cover all that they desired to lay before the licensing bodies. The Council should confine itself to general principles, and if those principles were not carried out, and they were sufficiently serious to warrant any interference with the privileges of the bodies, it would then be time enough to interfere.

Mr. SIMON seconded the motion.

Dr. HAUGHTON moved as an amendment the recommendation of the Irish Branch Council—viz., that the first two paragraphs of the existing recommendation should be omitted and the last paragraph retained.

Dr. BANKS seconded the amendment, which was agreed to.

Sir H. PITMAN moved the omission of Regulation 30, which specified the subjects to be included in the first and second divisions of the examinations. He said the principle was admitted in the clause just agreed to, and the Council had already expressed the opinion that they should not state in what manner the subjects were to be considered.

Dr. HAUGHTON seconded the motion.

Dr. STRUTHERS thought the Council might define what the final examinations should be, though he did not think they could possibly agree as to the earlier ones.

Dr. PETTIGREW said the Scotch Branch Council entered into the matter very carefully, and divided the examination into three divisions, specifying the subjects. From the students' point of view that was of very considerable importance, and he did not see what harm could accrue from such a scheme as was presented by the Scotch Board.

Mr. MACNAMARA said that they could not follow out the recommendations of the Council in Ireland, because their scheme of education involved examination at the end of each year.

Mr. TEALE moved as an amendment: "The final examination shall not take place till the termination of the full period of medical study, and should include medicine, surgery, midwifery, forensic medicine, hygiene, and mental diseases."

Dr. STRUTHERS seconded the amendment, but adhered to the opinion [illegible]

Mr. SIMON [illegible] general [illegible] purport [illegible] that the general proposals [illegible] were really better one.

Sir H. PITMAN said the subjects [illegible] those adopted by all the licensing bodies. They might be quite well left out. After all, they were but recommendations, and were not needed, as they had already been adopted.

On the suggestion of the President, the amendment was divided, and the first clause, "The final examination shall not take place till the termination of the full period of medical study," was agreed to.

The second clause, specifying the subjects, was withdrawn; and the first clause, on being put as a substantive motion, was agreed to.

Clause 31, "An examination in the earlier subjects of professional study should take place before the end of the first year of professional study," was omitted; and Clause 32, "The professional examination should be conducted both in writing and orally, and they should be practical in all branches in which they admit of being so," was agreed to.

With regard to Clause 33, "Not less than two examiners should take part in every oral and clinical examination,"

Sir H. Pitman moved the adoption of the English Branch Council's recommendation, which merely contained a verbal alteration, "Two examiners at least," &c.

Dr. Struthers seconded the motion.

Dr. Haughton said he approved of the recommendation heartily as far as the clinical examination was concerned, but there would be great difficulty in carrying it out with the oral examination. There was great risk of error in clinical examination, and therefore the necessity of having it conducted by two persons; but he did not accept the necessity of having two examiners in an oral examination or examination by papers.

Dr. Pettigrew said this rule was not made in the interest of the examiners, but of the students, so that they might feel that they were not in the hands of one man.

Mr. Macnamara said the opinion of the University of Dublin, as expressed by Dr. Haughton, was quite an opposite opinion to that entertained by the College of Surgeons in Ireland. They heartily concurred in the view the Medical Council had adopted, and had so recast their Court of Examiners that they were now in a position to have two at each oral or written examination.

Dr. Matthews Duncan thought it was not necessary in the case of the written examination to have two examiners to read every paper. With regard to the oral, speaking for himself as an examiner, he thought it extremely unsatisfactory to examine alone. It was a question, not of honour on the part of the examiner, but of responsibility.

The motion adopting the recommendation as altered by the English Branch Council was agreed to.

Recommendation 34, "The questions to be answered in writing should be submitted to the whole body of examiners for consideration and revision if desirable, before being proposed to the candidates," was, on the motion of Sir H. Pitman, omitted.

Recommendation 35: "The written answers should be submitted to more than one of the examiners."

Sir H. Pitman moved that this should stand as recommended by the English Branch Council: "The written answers should be submitted to at least two examiners."

Mr. Simon seconded the motion.

Dr. Haughton asked whether it was wise to put on record a number of recommendations which bodies for one reason or another would pay no attention to.

Dr. Duncan moved the omission of the clause, which was seconded by Dr. Haughton.

Dr. Haldane moved as a second amendment the recommendation of the Scotch Branch Council: "That a candidate should not be rejected on any written examination, unless his answers have been submitted to at least two examiners."

Dr. Pettigrew seconded the amendment.

Dr. Duncan said if one or two examiners read the written papers, those one or two did not reject the men; they merely laid them before the Board of Examiners for rejection. He therefore maintained that one was sufficient, and that this recommendation should be omitted altogether, because the papers were there for the whole board to read, and not for two only.

Mr. Macnamara said that in Ireland students were rejected on a written examination; but the papers were there to be referred to by the whole board if there was any question about the matter. He was in favour of omitting the recommendation.

Dr. Humphry could quite understand the Council leaving the matter to the licensing bodies; but they were not doing that; they were laying down certain general principles, one being that no part of an examination should be entirely conducted by one person. It was not casting the slightest slur upon the honour of the individual examined, but it was assuming that which they knew to be the fact, that examiners had sometimes particular views which they considered to be of vast importance. This applied to the written as well as to the oral examination; it was all very well to say the papers were before the board, and that they could look at them; the fact was the board did not look at them. He thought no part of the examination should be left to one examiner.

The amendment to omit the clause altogether was negatived.

Dr. Haldane's amendment was then put, and carried by 11 votes to 8. On being put as a substantive motion, it was agreed to by 12 votes to 6.

Clause 36, "Excellence in one or more subjects should not be allowed to compensate for failure in others," was agreed to, with the substitution of the words "other subjects" for "others."

Clause 37: "The professional examinations should be held by the several licensing bodies, except in special cases, at stated periods, to be publicly notified."

Sir H. Pitman moved the adoption of Clause 37 as amended by the English Branch Council: "The professional examinations should be held by the several licensing bodies at stated periods, to be publicly notified, and if, for exceptional reasons, special examinations be held, the fact, with explanations, should be notified to the General Council at its next meeting."

Mr. Simon seconded the motion.

Dr. Haughton preferred the existing regulation. The examination should be held at stated times, except in special cases, and those special cases ought to be very grave. He moved that the clause be retained as it already existed.

Dr. Pettigrew seconded the amendment.

Mr. Simon said it was felt that in certain cases special examinations would be necessary, and all that the English Branch Council asked was that if they were held they should be specially reported to the General Council. The amendment that there should be no special examination could not be universally accepted, and that being so, the Council desired to have some security applying equally to all the divisions of the kingdom.

Dr. Pettigrew said if it was known that the professional examination could be held only by the several licensing bodies at stated periods, to be publicly notified, it would take away all excuse for troubling those bodies to grant special examinations.

The amendment was agreed to.

Clause 38: "No university of the United Kingdom should confer any degree in medicine or surgery, whether that of Bachelor, Doctor, or Master, upon candidates who have not graduated in Arts, or passed all the examinations required for the Bachelorship in Arts, or passed, after due course of education, examinations such as are *bonâ fide* academically equivalent to those required for a degree in Arts."

Sir H. Pitman moved, and Dr. Haughton seconded, the omission of this clause, which was agreed to.

Clause 39: "As a general rule, none of the higher degrees or qualifications in medicine or surgery should be conferred on persons who have not shown evidence of higher professional attainments."

This clause was also omitted.

Clause 40: "In the examinations on several of the subjects of the curriculum—such, for example, as chemistry, including chemical physics, physiology, and materia medica—the licensing bodies should limit and define by schedule the extent of examination."

Sir H. Pitman moved that this clause be accepted, with a slight verbal alteration, as recommended by the English Branch Council.

Mr. Simon seconded the motion.

Dr. Pettigrew moved as an amendment the omission of the clause.

Dr. Haughton seconded the amendment, which was agreed to.

Clause 41 was agreed to in the following form: "In no case should the examination of a candidate in any subject be conducted exclusively by his teachers in that subject in the school in which he has been educated."

Clause 42, "Observation with the microscope should form part of the examinations of candidates for a licence," was, on the motion of Sir H. Pitman, omitted.

The adoption of Clause 43 was then moved by Sir H. PITMAN as altered by the English Branch Council: "Every candidate for the final professional examination should be required to give evidence that he has had sufficient opportunities of practical study, with care of patients, medical, surgical, and obstetrical, in hospital, dispensary, or elsewhere."

Dr. HAUGHTON seconded the motion, which was agreed to.

Clauses 44 and 45, providing that in examinations in anatomy candidates should understand that they might be called upon to perform actual dissections, and specifying the form of the returns to be made for the licensing bodies, were omitted.

The Council then resumed, and adopted the various recommendations agreed to in committee.

Dr. HAUGHTON moved: "That, in accordance with the recommendation by the Preliminary Examination Committee (Minutes for May 20th, p. 84), the examinations of the Queen's Colleges of Belfast, Cork, and Galway, and those conducted by the Civil Service Commission, be removed from the list of recognised preliminary examinations." The ground upon which this was recommended was because those examinations were superseded by the matriculation examination of the Royal University of Ireland, to which those Colleges were now affiliated. The committee also recommended that the name of the Civil Service Commission be also removed from the list, as their examinations were not fixed at a definite standard, but varied with the service for which they were intended, and also because these examinations were not attended by medical students.

Dr. STORRAR seconded the motion.

Dr. LYONS deprecated taking any step which would bring the Council into collision with the Civil Service Commission, which was one of the most powerful bodies in the kingdom at the present day.

Dr. HAUGHTON said the Civil Service Commission had sent in no answer to the questions forwarded by the Council.

Sir H. PITMAN said the Commission was very much surprised that it came to be put upon the list at all.

Dr. HAUGHTON said nothing could be further from their intention than the idea of giving such a body as that a slap in the face. It was a splendid body, but it did not want to be on their list; and the very fact that it was utterly unable to give the Council the information they wanted, showed that it ought not to be there.

The resolution was agreed to.

Dr. STRUTHERS moved: "That a more complete and continuous system of visitation of examinations is desirable, and that it be referred to the three Branch Councils to consider the subject and to report on it to the Council before its next meeting."

Dr. HERON WATSON seconded the motion.

Sir H. PITMAN said he was rather against pledging the Council to the statement "that a more complete and continuous system of visitation of examinations is desirable," but he saw no objection to the Branch Councils having the subject referred to them for consideration and report. He therefore moved, and Dr. Struthers was willing to accept the amendment: "That the question of a system of visitation of examinations be referred to the three Branch Councils for their opinion, and that they be requested to report to a future meeting of the Council."

Mr. MARSHALL seconded the amendment, which was agreed to.

Notices of motions by Dr. Lyons and Dr. Struthers having been withdrawn, the Council proceeded to deliberate in private upon the report by the Dental Committee with reference to the case of Charles Rudolph Werner, who was on Dec. 8th, 1884, convicted of misdemeanour at Edinburgh and sentenced to six months' imprisonment.

On the readmission of strangers, it was announced that the Council had resolved: "That the Council direct the registrar to erase from the Dentists' Register the name of Charles Rudolph Werner."

Mr. SIMON moved: "That the case of Mr. Bryceson, as regards his having caused himself to be registered as M.B. of the University of Cambridge, though not possessed of the qualification, be referred to the Executive Committee, and that the committee have authority to take, on behalf of the Council, such course as the legal advisers of the Council may advise to be taken, under Sections 29 and 30 of the Medical Act."

Dr. DUNCAN seconded the resolution, which was negatived by 10 votes to 7.

The PRESIDENT said, from communications which he had received, he had no doubt that he should have to summon the Council to an autumn session. He should take steps to ascertain what was the most convenient time. He tendered the thanks of the Council to Sir H. Pitman, the chairman of the Business Committee, and to the Registrar, for the admirable way in which the business had been conducted; and with this the sittings for the present session were brought to a close.

EXTENSIVE AND FATAL INJURIES, WITH FEW AND SLIGHT EXTERNAL EVIDENCES.

To the Editor of THE LANCET.

SIR,—I send you the following case, which occurred at Kingston-on-Thames this week, as showing what extensive and severe internal injuries co-existed with but comparatively trifling outward appearances:—

A coal porter was found in a crouched position on the line of metals in the railway station coal yard, on his knees and elbows, with his forehead on the ground, quite dead. At the post-mortem examination the external appearances were as follows:—There was a not very well marked bruise (i.e., small patches of ecchymosis here and there) in the front of the chest and abdomen, measuring 10 in. by 7½ in.; and a well-marked bruise, under cover of the upper arm, 3 in. from the apex of the axilla, measuring 6 in. by 6 in.; the abdominal wall was protruding about the umbilicus; and emphysema existed on both sides of the abdomen and right side of the chest; the left scrotal pouch was greatly distended. Such were the external appearances; but on continuing the examination the following injuries were revealed. The scalp, bone, meninges, and brain were normal. On examing the chest, numerous small ecchymoses were found, corresponding to the bruises, some also under the sternum and cartilages of the ribs on the left side, and on the visceral and parietal layers of the pleura. The left pleural cavity was filled with fluid blood, containing the spleen (torn in three places); the stomach separated from the gullet at one end and the pylorus at the other, and a portion of the liver about 4 oz. in weight. The left lung was penetrated (the spleen, stomach, and portion of the liver were forced through an opening in the diaphragm, admitting the double fist). The right pleural cavity was filled with fluid blood, containing numerous small fragments of liver, forced through a small tear in the diaphragm. The right lung was much bruised in its upper part; the heart was empty and natural. When opened the abdomen was found to contain numerous small clots and fragments of liver interspersed among the viscera; the major portion of the liver was reduced to pulp, and what remained was traversed by fissures in all directions. Many mesenteric veins were ruptured; four yards of small intestine were forced into the left scrotal pouch, and about one yard and a half into a small pouch in the perineum. The bladder was ruptured to the extent of admitting four fingers, and the symphysis pubis was fractured. The right kidney was torn in three places, and the suprarenal body smashed. The left kidney was bruised, with three extravasations of blood, and the suprarenal body smashed. The aorta was completely ruptured on a level with the fractured spine, and lacerated three inches lower down. The left psoas muscle was ruptured and pulped. The third rib on the right side was fractured in front; and the fourth, fifth, sixth, seventh, eighth, ninth, tenth, eleventh, and twelfth ribs were fractured and splintered in various places, some in two and others in three. The first rib on the left side, close to the sterno-clavicular articulation, and the ninth, tenth, eleventh, and twelfth ribs were also broken. The ligaments of the ninth and tenth dorsal vertebræ were torn across; the tenth dorsal vertebra was fractured across, and the spinal cord and membranes were also severed. The vertebræ on the left lateral aspect from the second lumbar vertebra were fissured upwards to the transverse fracture of the tenth dorsal vertebra. The transverse processes on the right and left of the lumbar vertebræ were fractured, that of the second left lumbar vertebra in two places. The bones of the extremities were sound.

The man had evidently been nipped between the buffers of heavy trucks and dropped on the line, where he was found.

I am, Sir, yours truly,

Kingston-on-Thames, April 28th, 1885. E. M. SHIRTLIFF.

THE LANCET.

LONDON: SATURDAY, MAY 30, 1885.

IT is a notable remark of HUME'S, that the ancient history of England is nothing but a catalogue of reversals; everything is in fluctuation and movement; one faction is continually undoing what was established by another. So it is, *mutatis mutandis*, with the Medical Council, which has just finished one of its longest and least creditable sittings. All its laws are in a state of fluctuation and movement, and with the less excuse, as it is a continuous body, made up for the most part of the same individuals. Nevertheless, its Recommendations are continually being reversed, and a great part of the time of one of its meetings *is occupied in undoing the Recommendations which occupied* a great part of the time of a previous sitting. The last meeting affords a striking illustration of this charge. No less than seven or eight of the chief Recommendations of the Council were erased, which comes to very much the same thing as reversal. Let us enumerate a few of these Recommendations. We remember that some of them were argued and fought for by some of the best members of the Council, and, if we mistake not very much, some of them have received their quietus from gentlemen who a few short years ago fought bravely for them. But to the actual reversals. If there was one thing more than another that the Council seemed agreed upon not long since, it was that there should be an examination *at the end of the first year*, with the view of giving the young student a sense of responsibility sooner than he is apt to feel it. At the recent sitting this Recommendation was omitted. Perhaps the one point on which there was, two or three years ago, the greatest consensus of opinion was that in examinations in certain subjects, as chemistry, chemical physics, &c., there should be a limitation and definition by schedule of the area or extent of examination. And this limitation was enjoined in Recommendation 40. Recommendation 40 has now been omitted, and henceforth the poor candidate will have no guide in the trackless and vast domain of these wide subjects. A most wholesome Recommendation (22) was passed a few years ago, asserting that no licensing or teaching body should insist on more than one course of lectures on any one subject. The "lecturing" element in the Council has attacked this Recommendation with success, and it is gone, and there is nothing to prevent teaching and licensing bodies exacting an unreasonable attendance on several courses of lectures on the same subject; in other words, an unreasonable amount of fees on every subject in the curriculum. This is the kind of work which brings the Council into disrespect. The reversals which we have instanced, our readers will see, are only specimens; but they are very significant ones, of great moment to medical students. Their moment is increased by noticing how the Council has been extending the curriculum, adding new subjects, and doing its best to add to the time to be spent at a medical school. This may be all right; but it is very unfortunate that such burdens should be imposed by a Council so deeply representative, not of the student or the practitioner, but of examining and teaching bodies, whose interest—we will add whose pecuniary interest—lies in prolonging and complicating the process of medical education. As our readers know, we are not of the number of those who see any immediate prospect of the public being undersupplied with medical men. We have shown frequently of late how ample is the supply of medical students, and how crowded are the ranks of the profession, leading in most places to a competition and pressure which in the professional sphere are not a little unseemly. We have pointed out that this state of matters justifies the Council in any reasonable measures for correcting laxness in medical education, and for improving the quality and methods thereof. But in the positive legislation of the Council there is too much suggestion of mere blind faith in lectures, time, medical schools, &c. On the motion of Dr. HALDANE, *the time of study to be required* of medical students is no longer three winter and two summer sessions, but "four winter and three summer sessions," and all this to be "passed at a school or schools recognised by any of the licensing bodies in Schedule A of the Medical Act." There is an extensive and a growing impression outside the Council that one conspicuous defect in the education of medical students nowadays is their ignorance of ordinary practice, and that one great improvement would be to require a certain time of the student period to be spent in private practice under the supervision of a private practitioner, whose work would supply cases and experience which are not to be met with in hospital practice. *But such practical methods* have no favour with the Council, which believes in nothing but the Schools recognised by the infallible nineteen bodies mentioned in Schedule A. How different might medical education be if the Council contained fewer representatives of those charmed bodies in Schedule A, and a few of the representatives of the men that carry on the actual medical practice of the country. Again, Dr. BANKS has succeeded in passing a resolution extending the curriculum over five years. As we explained last week, this resolution was so modified as to be not so formidable as it looks. It was made only to apply to cases in which certain preliminary subjects—elementary mechanics, physics, chemistry, and biology—had not been disposed of before the commencement of strictly medical work; and such cases are supposed to be exceptional. Still Dr. BANKS's motion is the expression of the wish of the Council to extend the length of time spent in medical schools, for which undoubtedly he adduced some *powerful arguments*. What is to be regretted is the constant change of the Recommendations of the Council, and *the fact that the very constitution of the Council* gives colour to the charge that the members of it are thinking more of the bodies in Schedule A which they represent than of the poor overburdened medical student who had ten subjects on his back before the recent meeting, and has now twelve, with the prospect of five or ten more if some other Council be not devised, or some other method of using the time and money of the present one. One resolution of much interest, proposed by Mr. MARSHALL, was passed—viz., to appoint a small committee, consisting of Dr. HALDANE, Dr. A. Smith, and himself, to superintend the preparation of statistical returns relating to the medical profession. The Council has the materials of such statistics, and it has the money to have them analysed and certified. We have seen lately how much the facts about the profession may be misstated, to the great detriment of it and the public. We feel thankful to Mr. Marshall for his resolution, and expect to feel much more so for the work to which it commits him and his colleagues—two gentlemen very likely to prove useful co-operators, and one of whom, Dr. Aquilla Smith, has already done good work of the sort.

◆

The paper which Dr. Angel Money read at the meeting of the Royal Medical and Chirurgical Society on Tuesday last was an original contribution to experimental pathology, having an important bearing on clinical medicine. The investigation clearly showed that a great variety of clinical phenomena could be brought about as the result of embolism of the capillaries of the spinal cord and brain. Dr. Money went further than this, and generalised to the effect that any symptom or group of symptoms could be caused by obstruction of the smallest bloodvessels. It is not improbable that the generalisation will be found to hold good. Indeed, as was argued by the author of the paper, the number of symptoms observed in the experimental investigation was sufficient to defend the position which had been taken up. Sudden death, cerebral and spinal paralysis, simple twitching, rhythmical twitching, choreoid movements and the so-called *mouvement de manège*, movements of rotation, and other forms of these "forced" or "uncontrollable" movements, were all observed as immediate effects of the introduction of granules of starch into the arterial circulation. Many of the symptoms were observed in one and the same animal. The most important observation which Dr. Money claims to have made was the occurrence of a succession of different movements, such as could not, allowance being made for the anatomical difference between animals and man, be distinguished by him and several other gentlemen from the movements of human chorea. There is almost overwhelming evidence of the dependence of most cases of chorea in the human being on disturbance primarily in the *brain*, but it is by no means certain that chorea may not be caused by lesions situate lower down than the basal ganglia. And the experiments were held to prove that in the cat and guinea-pig these choreoid movements were the result of nervous discharges originating in the nerve-cells of the spinal cord. The evidence on this point appeared to be conclusive. In a cat the abnormal movements were limited, roughly speaking, to the upper half of the body, the reflex actions were greatly exaggerated over this area, and the autopsy showed the granules of starch only in the vessels of the upper half of the spinal cord. There were no movements and no exaggerated reflexes in the lower half of the body, and no emboli in the lower half of the spinal cord. Emboli were widely scattered in the brain in the same cat, but that the cerebral lesion was not the cause of the choreoid movements seemed to be proved by the foregoing and following considerations. When in another cat the emboli were shot up the internal carotid artery and only reached the brain, no choreoid movements occurred in the limbs or trunk, and there was no obvious alteration in the state of the reflexes. Dr. Hughlings Jackson, in the course of the discussion, remarked on the importance of the discovery that irregular movements, of no matter what kind, might be caused by capillary embolism. He also argued that in the cat and other animals, whose cerebral and muscular structures were very different from those of man, it was impossible for the varied movements of human chorea to occur, for the reason that these animals did not possess the mechanism for the production of such movements. The question remains, "Does human chorea ever result from capillary embolism?" Dr. Hughlings Jackson, Dr. Broadbent, and the author of the paper are of opinion that some cases of chorea may own this causation. Several pathological observations have been recorded tending to prove this point; but it must be confessed that until we have in our possession a series of experimental investigations on the nervous system of such animals as monkeys, whose nervous system approaches nearest to that of man, the question must remain unsettled.

Dr. Head

◆

We invited attention in a recent number to a company which had been proposed for insuring lives without the assistance of the members of the medical body as advisers on the question of the life of the insurer. We now direct the notice of our readers to certain other proposed or *de facto* companies, in which not the life exactly but the health of the assured is provided for. It would appear that there are at the present time no fewer than three of these last-named companies before the public in competition for favour. The first of these is called the Medical Attendance Assurance Association; the second, the Health Assurance Association; the third, the Sickness and Accident Assurance Association. The object professed by the Medical Attendance Assurance Association is to indemnify its insurers against the expense of providing adequate medical attendance for themselves or their families during illness resulting from disease or accident the insurers, subject to mere nominal restrictions, having the option of selecting their own doctors. This is the first part of the programme; but there is a second, in which it is provided that the company shall indemnify, by weekly allowances or compensation, those whose source of income fails during illness, or shall recoup these persons the loss accruing through having to employ a substitute during illness to attend to their duties or business. The other two offices embrace in their plan the latter part only of the above. They propose to recoup the sick for losses sustained during sickness; and the Sickness and Accident Office, as its name implies, takes up accidents as well as ordinary illnesses. With both these last-named offices medical attendance is, so far as we can see, self-provided. The sick select and pay their own medical advisers.

The idea of an insurance for sickness amongst the richer classes is not altogether novel, although it has never yet been carried out to a sufficient extent to prove its value or its success. But practically in the sick club system the scheme has been tried amongst the working classes. In most of the sick clubs the provision for medical assistance is secured by the services of one medical man for one club. But there are, or if there are not now, there have been clubs in which the patient has had the right of selecting his own doctor, just as is suggested in the Medical Attendance Assurance Office. In this experience, therefore, we find the test of the whole subject. Again, we find the test of the whole question in those dispensaries in which the subscribers have the right to make their own medical selection. We are not prepared to say that the system which in these cases is in practical operation is always bad in its working. In some instances we must acknowledge that it acts fairly well. There are, however, elements of success in such instances which do not exist when the wealthier classes of the community come under the experiment. In the poorer classes the rate of fee for medical assistance is at one and the same time very moderate, and taking it all in all very uniform. In plain terms, the sick adopt the plan because it respectably suits their modest means. They could not easily get the required advice more cheaply if they were not subscribers to the club or dispensary; and they understand that, under the advantage of the system, they are obtaining, often from the same practitioner, the self-same benefit as other and wealthier patients obtain at a much higher cost. Therewith they are satisfied. If they were rich they would not be satisfied, a fact which is proved every day from the well-known circumstance that as men rise in the social scale they pass in the doctor's books from the dispensary or club book into the private book.

In forecasting on the scheme of the first-named new company, we have to ask if it is probable that patients who can, if they will, pay any reasonable fee to any physician, surgeon, or accoucheur, will consent to tie themselves to a method the whole success of which will depend either on a levelling system of payment or on the introduction of a third or middle agency between the sick man and his skilled adviser. We consider that the forecast is not favourable to the scheme, but if we should prove to be wrong, our mistake will be succeeded by a social change in medicine, a socialism which in a few years will bring about an entire revolution, leading probably to the abolition of fee-taking and book-keeping altogether, and to the institution of an order of practitioners remunerated by districts or communities in fixed annual stipends, and bound to give their services to all who summon them. The club doctor in high places, receiving an annual income in quarterly payments, will then be *Fortunæ filius*; and the electrical attraction of the gold and silver piece wrapped in mysterious envelope and handed with more mystery, will remain only as a memory.

◆

Opinion as to the best mode of treating the wound left after amputation of the mamma, is much divided just now in Paris, opposite views being firmly held by surgeons of equal eminence and experience. On the one hand, we have a school led by M. Verneuil, teaching that no attempt whatever should be made to secure healing by primary intention, but that the large wound left after free removal of the breast and of the axillary lymphatic glands should be allowed to close by granulation. In support of this view they allege that when the operation is properly performed it is impossible to secure union by first intention, and that the attempt to do so induces surgeons to narrow the limits of the operation, and so to render recurrence of the disease more certain and more rapid. They further assert that the opposite practice is dangerous, as it increases the liability to erysipelas and other forms of blood poisoning, and that the time taken for the final healing of the entire wound is not at all, or not materially, diminished. On the other hand, we find MM. Trélat, Championnière, and Polaillon representing another school, and holding equally firmly that as a rule union of the wound by first intention is not only the quickest but the best mode of healing in the majority of cases, and that when properly carried out, after a carefully planned and executed operation, it does not expose the patient to risk of local or general poisoning, or increase the danger of recurrence of the malignant neoplasm. When views so divergent are expressed by such high authorities upon a line of practice very common in the experience of all operating surgeons, a careful consideration of the question is demanded by all engaged in this department of practice. As in other similar cases, we should expect to find much of truth on each side.

Three points are to be considered in operating for cancer of the breast: the successful removal of the disease, the safety of the operation, and the speedy restoration of the patient to health. The relative importance of these points depends upon the view that may be held of the value of the operation. If it be held that it is impossible or impracticable so to operate as to prevent altogether, or to postpone for more than a short time, recurrence of the disease—if, in other words, the advantage of the operation be slight, then the certainty and speed of recovery from the operation become of greater relative importance than in the opposite condition. Where the possible advantage to be gained is great, the price to be paid for it may not unreasonably be increased. When we apply this test to amputation of the breast we find that while the success of the operation in retarding or preventing recurrence is only too small, yet it is such as to justify the surgeon in asserting that in well-selected cases he may hope to postpone recurrence of the disease for many months or years, if not permanently. From this point of view the thoroughness of the operation becomes the chief aim of the surgeon, in comparison with which the other considerations named are of secondary importance. Where, on the other hand, in more advanced cases of disease, the utmost that can be hoped for is an amelioration of the patient's condition and a short respite from the ravages of the disease, the severity of the operation assumes serious proportions, and the value of any means that render the safety of the patient greater and her recovery more rapid is proportionately increased. In cases that are favourable for the operation the parts should be very freely removed, all outlying portions of the mammary gland being carefully sought for, and the axillary glands, even when not palpably affected, excised. About this all surgeons are agreed, but it is necessary to insist upon the thoroughness of the removal as shown by the time elapsing before the reappearance of the disease as the one test by which success or failure of an operation is to be judged. The surgeon must decide in each case how the operation is best to be planned, and it is wrong to lay down any rule as to the extent of skin or other tissue to be removed, different cases requiring quite different treatment in this respect. But this imperative demand for free removal of the disease having been met, and the wound inflicted, the question arises whether there is any reason why one method of healing is to be preferred to another. It is no doubt true that great care and attention are needed to secure healing by first intention, but there is also no doubt that in many cases such care and attention are rewarded with complete success, and that the period of convalescence is rendered considerably shorter than under any other mode of healing. And unless the surgeon neglects making proper provision for drainage, and fails to protect the wound by a thorough use of antiseptics, he does not expose his patient to the danger of erysipelas and other infective wound diseases. Nor is there any *a priori* pathological reason why healing by granulation should be preferred to that by primary adhesion. The resemblance between the cancer cell and the rapidly formed and growing masses of protoplasm found in granulation tissue is an argument in favour of healing by first intention where the amount of lymph effused is reduced to a minimum, and where also the vascular hyperæmia is less and of shorter duration than in healing of a large wound by granulation. The influence of hyperæmia upon the growth of cancer is well known, and should the surgeon leave behind in his wound any cancer "germs," or cells prone to take on the cancerous development, it is in accord with pathological doctrine and clinical experience that prolonged hyperæmia and abundant cell growth of low type might stimulate the germs or disordered cells, and lead to a rapid recurrence of the disease. While, therefore, we cannot but think that the doctrine of M. TRÉLAT is sounder than that of M. VERNEUIL, we fully endorse the latter's caution, that, in attempting to secure rapid healing of his wound, the surgeon may consciously or unconsciously lessen the extent of tissue removal, and so sacrifice the greater to the lesser good. We would state the matter thus. In planning and carrying out his operation the surgeon should think only of the wide and efficient removal of the disease, without regard to the mode of healing of the wound; but having made the wound, if he finds it practicable to obtain healing by first intention, he should certainly direct his efforts to that end.

◆

THE *furore* excited by Dr. FERRAN's alleged protective inoculation of cholera continues unabated, or rather with increasing ardour. Last week it was reported that he had operated upon 8000 persons in Valencia alone, including two Madrid doctors—MORENO and TOLOSA—who thereby became converts to the new doctrine. It is also stated that four hours after their inoculation they experienced the cramps, diarrhœa, fever, and delirium of cholera, and that after sixteen hours "they were all right again." Farther proof of the efficacy of the measure is cited from the Alcira Hospital, where all the inmates were inoculated, with the exception of two, who declined to submit to the operation. Cholera attacked these two recalcitrants, and they succumbed to the disease. In the face of these and other facts, Dr. CAMERON did well to ask the Secretary to the Local Government Board whether he would consider the propriety of nominating a small commission to visit Alcira and report. He stated that Dr. FERRAN was desirous that an English Commission should be appointed to verify his results. Mr. RUSSELL, in his reply, promised to bring the proposal under the notice of the Secretary of State for India; but we venture to think that it would be better to send the Commission from England, as the question is one which directly involves the subject of choleraic micro-organisms that have been so much studied by a few of our scientists. It may be remembered that Dr. FERRAN adheres to the bacillary doctrine of the etiology of cholera, but that he declares that KOCH's comma bacillus is but one stage in the development of an organism, whose germs he avers to have discovered. Although we are unwilling to condemn on *a priori* grounds a discovery of such moment as this would be if verified, we are yet very reluctant to admit that such vaccination can protect from true cholera, or to see in the results as reported anything more than coincidences. Asiatic cholera is not prevalent in Alcira, nor, so far as we know, has it reappeared anywhere in Europe this year, and therefore the conditions of a crucial test are wanting. We are not surprised at the excitement that has been caused by the announcement of the alleged prophylactic; for the history of epidemics of this disease shows how much the people dread its invasion; and they would willingly submit to any measure that promised them immunity from the plague. It is significant that at the recent conference at Berlin not even Dr. KOCH himself as much as hinted at the possibility of a protective vaccination amongst the measures of meeting the disease; and FERRAN's work was only cursorily mentioned by one speaker, Professor VIRCHOW, who believed that the various forms described by FERRAN were the results of disintegration of the bacilli, and not stages in their evolution. The matter has, however, reached a stage in which it ought not to be disregarded without a full and sufficient investigation; and although we doubt very much the possibility of arriving at any satisfactory conclusion except in time of epidemic, it is very desirable that Dr. FERRAN's labours should be submitted to such an examination by competent and trustworthy authorities. We fully approve of the step somewhat tardily taken by the Spanish Government in prohibiting any further inoculations until such inquiry has proved the efficacy of the measure. For if the whole thing be proved fallacious, the task of dispelling the delusion will be the greater the larger the number of the inoculated; and if it be shown to be really efficacious, no harm will be done by deferring it until this is proved. The position of Dr. FERRAN is a difficult one; for, although he has acted in good faith, he must either be a misguided enthusiast who has pushed his conclusions far beyond their legitimate limit, or a great discoverer. Pending such an inquiry it would be unfair to judge him, but we cannot refrain from once more pointing out that to rely upon "protective vaccination" and to suffer the continuance of those insanitary conditions that favour the spread of cholera would inevitably lead to disastrous results. Nor is it possible to view with equanimity the prospect of an application of these inoculation measures to other specific diseases, an extension which would be sure to be attempted if Dr. FERRAN were proved to be in the right.

DR. WILKS has accepted the invitation of the Council of the Midland Medical Society to deliver, in November, the inaugural address of the session 1885-6.

Annotations.

"Ne quid nimis."

THE COLLEGE OF PHYSICIANS AND THE CROONIAN TRUST.

It is but seldom that a medical corporation is troubled with an *embarras de richesses*. But this is the peculiar good fortune of the Royal College of Physicians at the present time. In 1706 Dame Mary Sadlier founded the "Croonian Lectures," and instead of the amount of the modest fee which has hitherto been paid to the lecturer the College finds itself in possession of the annual sum of £207 net under her bequest. It is obvious that no such sum can be devoted to a course of lectures for which £10 has previously been found a sufficient remuneration. The College therefore recommends that application be made to the Court of Chancery to vary the deed of settlement, and the Council recommends the following scheme for the consideration of the Fellows:—

"That the present 'Croonian Lectures' be continued with a salary of twenty guineas, being double that which it is at present. That the residue of the income from the trust, after payment of the Croonian Lecturer, be invested to form a fund for the establishment of a Professorship of Anatomy and Physiology, the person holding such professorship to be called 'The Croonian Professor of Anatomy and Physiology,' and to hold such professorship for five years. That the appointment of such professor, who shall deliver such lectures as the College shall determine, be made within a period of five years from the decree of the Court."

Several Fellows have proposed amendments which would limit the tenure of the professorship, and would bring before the College any new researches, not only in anatomy and physiology, but also in therapeutics and pathology; and we can have no doubt that, in view of other lectures at the College of Surgeons and the University of London, the Fellows will expect a wider departure than is suggested by the Council, and one that will not compete with the usual lectures now annually given in London. A five years' professorship is absurd, when we consider the rapid increase in our knowledge, and the varying lights in which such knowledge may be put before our profession. In fact, we would ask, Could not the large increase in the trust fund be better used than in endowing another lectureship, if twenty guineas were paid instead of ten for the annual course now given? A more detailed and comprehensive scheme than that which is under consideration would be preferable to a hasty decision in the direction of an increased number of lectures, which would be attended by but comparatively few Fellows or other members of the profession.

THE PENAL ACTION OF THE MEDICAL COUNCIL.

A large part of the time of the Medical Council is taken up with judicial duties. While so occupied reporters are excluded, and only very limited information is afforded as to the grounds and arguments on which the judgment of the Council is founded in any given case. This is to be regretted in some respects. Courts of judgment, like courts of law, should, in general, be open courts, alike in the interest of those judged and of the profession to which they belong. The Council has erased from the Medical Register four names of medical men, as will be seen in our reports, and one name from the Dentists' Register. As far as we can gather, it is impossible to accuse the Council of severity in these cases. There is one great defect in the legal position of the Council as regards cases of misconduct. It has no power to deal with conduct otherwise than "infamous," and it has only one punishment to inflict—viz., the supreme one of removal from the Register. There is much misconduct, to which the word "infamous" could scarcely be applied. And it is in the highest degree to be regretted that the Council has not power to take cognisance of conduct that is unprofessional rather than infamous or against the public interest, and to censure, or apply degrees of punishment less than that of the capital measure of erasure. The medical authorities in Schedule A, indeed, or some of them, have such powers, but they are sorely hampered in using them, so that some who hold their diplomas go from one degree of unprofessional conduct to another with apparent impunity, till at last they outrage public law or morality and incur the one great punishment of disqualification and consequent erasure. One word of kindly warning at an early stage from the Medical Council, or from the body to which they owe their diploma, might have saved them. But it is withheld, and so it comes to pass that half the time of the Medical Council is taken up with examining gross cases of infamous conduct, and no attempt is made to deal with hundreds of instances of unbecoming and unprofessional conduct. It is not so in other professions, as was well pointed out by a correspondent last week.

THE REPRESENTATION OF THE EDINBURGH AND ST. ANDREWS UNIVERSITIES.

Sir Lyon Playfair has rather abruptly intimated his intention of not offering himself at the next election as a candidate for the representation of the University of Edinburgh. We do not forget the part that Sir Lyon Playfair has played in hindering medical legislation and in misleading the House of Commons with erroneous statistics of the profession. In view of this action, we cannot pretend to regard his withdrawal from the post which he fills with unmixed regret. The large medical element in his constituency, and his supposed relation to the profession, gave more serious importance to any such action on his part. We are little concerned with the political bearings of the step taken by Sir Lyon Playfair. But we will take the liberty of hoping that the seat will not be wasted on some aspiring lawyer, who is always ready to profit by such opportunities. Parliament is full of lawyers, and it is conspicuously deficient in representatives of science. We commend to the constituency of the metropolitan University of Scotland the claims of science, and urge them to elect a man who will worthily represent it, and who will magnify the university by recognising in it a national institution, which exists not for Scotland's benefit alone, but that of the empire. The Scotch universities have sometimes acted as if they were parochial institutions, with all the jealousy of public criticism and check which such institutions are apt to feel. The election of a great public man, one who by science or by statesmanship has shown himself to be above mere party politics, will be creditable to the University and advantageous to the State.

POSITION OF THE FŒTAL HEAD AT TERM.

As an inaugural thesis in the University of Dorpat, L Brühl has published some observations on the position of the fœtal head and the extent of its entrance into the pelvic cavity at term. In primiparæ the greatest circumference of the head was found to have passed the brim at the end of pregnancy in half the cases. In multiparæ it only reached the pelvic cavity in a fourth of the cases. The reason of the difference is to be found in the greater elasticity of the abdominal wall and of the uterine ligaments in primiparæ. In contracted pelves, where the conjugata vera measured less than ten centimetres in primiparæ, the head entered the cavity in only a third of the cases, the greatest circumference in scarcely any passing the brim, and in subsequent pregnancies the position of the head became higher more rapidly than was the case in normal pelves. The prognosis of labour depending upon the relation which exists between the fœtal head and the maternal passages, it is the practice in Berne, where these observations were made under the supervision of Professor P. Müller, to grasp the fœtus through the abdominal wall and force the head as far as possible into the pelvic canal at the completion of pregnancy. Generally, when the head has more than half entered the pelvic cavity one can predict that birth will take place naturally. On the other hand, it is by no means necessary to infer that instrumental interference will be required in all cases where the head has entered the canal to only a slight extent.

THE HOMES OF THE POOR.

THE publication of the Report of the Royal Commission on the Dwellings of the Working Classes brings more prominently to public notice the relation of vestrymen in London parishes to insanitary tenement houses. We read of a recent meeting of the Clerkenwell vestry, at which a complaint was received through the Local Government Board of the condition of certain premises in that district belonging to a vestryman, and that complaint had been made to the vestry and no action taken. In the course of the discussion it was stated that "several vestrymen made a good livelihood by being house-farmers." There may be no objection to the owners of tenement houses being represented in due proportion upon the local authority, but where officers hold their appointments entirely at the will of people of this class it becomes obvious that they are likely in some cases to be deterred from carrying out their duty. If tenants could obtain damages against their landlord for injury to health, the result of living in an insanitary dwelling, there would be less need for the interference of the sanitary inspector; but this is not possible except where a previous guarantee has been given that the house is in proper sanitary condition. In a recent action for rent in the Clerkenwell county court the defendant denied his liability to pay on account of the insanitary condition of the house, and gave a melancholy account of its defects. The verdict was necessarily for the plaintiff, but the judge expressed his disapproval of the plaintiff's conduct in letting so faulty a dwelling by declining to award costs. An appeal here to the local authority should have been sufficient; but, as the judge said, "It seems from the inquiries of the Royal Commission that public bodies will not put the law in force." The immediate remedy is obviously in the hands of the public, who have it within their power to return as vestrymen those who are more interested in seeing the law carried into effect than evaded.

DR. BRADLEY'S CASE.

WHY does the Home Secretary maintain such silence after the influential petition presented to him on behalf of the convict—a petition signed by "more than one thousand physicians and surgeons"? We have repeatedly drawn attention to the unsatisfactory verdict returned by the jury. In the interests of justice we join in the request—nay, the demand—for an immediate impartial inquiry into the merits of the case. Apart from the fact that many of the alleged acts by Dr. Bradley given in evidence at the trial were physically impossible of accomplishment, there is reasonable ground for declining to accept the theories of the prosecution as regards the main charge. In some cases clemency on the part of the Crown implies a want of belief in the *bonâ fide* of the witnesses by whose testimony the conviction was obtained; but here no such alternative supposition is necessary. The prosecutrix was shown to have suffered from epilepsy, and to have inherited a tendency to neurotic taint. What more likely, then, that imaginary wrongs were conceived by her during a transient aberration from normal innervation, and afterwards registered in her mind as accomplished facts. From whatever standpoint the merits of this unfortunate case are viewed, the same conclusion is inevitably arrived at—viz., that the conviction was utterly unwarranted by the evidence. We do not plead for mercy, but ask for justice. Here is a man who, previous to this fatal incident, bore professionally a spotless character, and is that character to be destroyed by a mere legal technicality? If the necessary scientific knowledge is not possessed by those who have the issue in their hands, in the name of common sense and public duty let those who understand such matters be left to decide whether Dr. Bradley shall be restored to his friends or finish his fearful sentence of "two years' imprisonment with hard labour." In the event of Sir W. Harcourt still refusing to reply to the appeal long since lodged with him, we pray that he may be moved to action by the general body of the profession.

ANTI-VACCINATIONISTS AND THE GORDON MEMORIAL.

THE Committee of the Gordon Memorial Fund have given evidence of shrewd judgment and sincerity in their reception of an offer lately made to them. The report reaches us from Leicester that a lady expressed her wish to hand over to the committee a house with adjacent grounds, to be used as a home for boys subject only to the proviso that vaccination should not be an essential to admission. The proposal was declined. This lady no doubt meant well, and she naturally feels aggrieved that her principles are not to be accepted along with her gift and its benevolent motive. She is clearly one of those who regard vaccination as a tyranny, fruitful of disease which cannot possibly have arisen otherwise than as stated by anti-vaccinationists, as a useless measure, and a law which it is right and lawful to break. The committee, however, think otherwise, and we venture to say that in their present action they will have the support of all who are in possession of the facts on both sides of this important question. No blame can be assigned to them for the loss of the memorial home, however regrettable that may seem in the interest of the poor. General Gordon's own abundant charity would never have sanctioned even such a gain at the cost of conscience, and the committee, in refusing the responsibility for lives which they could not protect in case of illness, have only followed the example of his enlightened rectitude.

CORPORAL PUNISHMENT AT SCHOOLS.

THE relationship between cause and effect is in many cases notoriously difficult to establish by logical proof, however clear it may be in its *primâ facie* aspect. The tendency with all of us is to seize upon the latest antecedent circumstance, and to assign to it the credit of causation. A case in point is afforded by an inquest held a short time ago at Sittingbourne. A delicate boy, eight years of age, died a few days after having received a whipping at school. The symptoms which preceded death were those of meningitis, with convulsions, and post-mortem examination verified the presence of this disease. Mr. T. Smith, the surgeon who attended the child, could see no clear connexion between the fatal disease and the whipping, but allowed that the shock of the punishment might possibly have had some effect in determining the course of the illness. The jury found a verdict accordingly, but severely censured the schoolmaster for cruelty. We do not approve of severe bodily chastisement for children at school, but it seems to us nevertheless that a somewhat forced connexion has been established in this case between the punishment inflicted and the disease which was afterwards observed. Inflammation of the brain membranes is one of the most deadly enemies of child-life, and is far more apt to appear as the climax of an undefined constitutional delicacy than as a consequence of injury. Dormant in many children from their inherited feebleness, its chief provocatives are recognised by all practitioners to be want of nutritious food, fresh air, and exercise. It may well be that the weakly child in the present instance owed his death to these commoner evils rather than to his master's harshness. We do not learn that he was beaten about the head, though at the same time it seems clear that the rod was used with more than necessary freedom. The lesson, however, which is most apparent from the facts is that there are young children in school-training for whom their discipline and tasks are equally excessive, and who are, as they stand, unfit to be at school at all. Usually ill-health can be detected by a careful parent before this stage is reached, but it does not necessarily afford such proof as to have allowance made for it under our compulsory educational system. The jury's finding of cruelty, which may have been fair enough in itself, falls short, in our opinion, where it fails to recognise that work as well as punishment should be light in the case of weak children, and that hunger and fatigue may sometimes cause as much injury to health as positive hard usage. Already measures of reform are on foot in many schools. Cheap and good food and recreation hold a definite place in their management; and we may soon be fortunate enough to note a decline in the cramming system, and the adoption of some plan of efficient medical supervision.

VICTOR HUGO.

The typical Frenchman is dead, and Paris—ay, France; Paris is France—honours his obsequies with bombast and blood. This genius, for Victor Hugo was a genius, and of a very exalted order, played the *rôle* of Chorus to the evolution of intellectual life and power in the people of *la belle France*. He was the poet of the Revolution. Whether he wrote in prose or verse, he was a poet; and no man perhaps ever moved the nation, for whom he lived and thought and wrote, more powerfully. It was not Victor Hugo's fault that his works did not contain more of mind and less of emotion than characterised them. They were the reflex of the mental growth of the period. Had they been of higher calibre, they would have been false to their key-note, out of tune with the spirit of the time. It will be long before France finds as faithful an expositor of the national feeling. Victor Hugo's chamber was the scene of a gallant struggle of life against death. Death vanquished the victor. The man died, but his manly work remains.

DIAGNOSIS OF SMALL-POX.

Dr. Collier, medical officer of health to the Fulham District Board of Works, in his report for the fourth quarter of 1884, raises a question of some importance to the public. On November 24th he received private information that a girl residing in Westcroft-square had been ill and had had a rash upon her. Visiting the house, he found she was suffering from modified small-pox, and another child was ill with the same disease. The mother had objected to the removal of these patients to hospital, owing to the opinion of the medical attendant that they were suffering from chicken-pox. The first patient had been residing as servant in a house at Richmond, and had returned home with the spots upon her. Her late master had died after a few days' illness. He had been seen by several experienced medical men, and his death had been registered as due to "hæmorrhagic measles." A short time after his death his three children were taken ill; their disease was first thought to be measles, but afterwards chicken-pox. A woman employed to wash the clothes of the father contracted small-pox in a severe form. Nine days after the removal of the cases from Westcroft-square the stepfather of these children was attacked with small-pox. There can be no reasonable doubt that all these persons suffered from small-pox, yet the disease had not been recognised by the medical attendants in the majority of cases. It is very necessary in the public interest that medical men should have an opportunity of making themselves thoroughly acquainted with the different appearances of this disease; medical students in the metropolis are now debarred from doing so owing to the fact that the public institutions receiving these cases are closed to them. We do not desire to dictate to the managers of the Metropolitan Asylums Board in the precautions which they feel it necessary to take to prevent the spread of small-pox from their hospitals, but we believe that it would be quite possible to enable medical men and others to visit these institutions without risk to the public.

HOUSING OF THE WORKING CLASSES IN SCOTLAND.

The evidence obtained by the Royal Commission on this subject shows that although on the whole the Scotch are better off than the English working classes with regard to dwelling accommodation, there is still the same absence of provision for the very poor. The number of single-roomed tenements, each of which is usually occupied by a family, is very considerable; in Edinburgh there are 14,000 of such tenements, and in Glasgow 5 per cent. of the population live in single rooms. Extensive improvements have been carried out both in Edinburgh and Glasgow with good results. The recommendations of the Commissioners are much the same for Scotland as for England, and among others include that the amount of cubic space demanded for each individual should be increased with a view to discouraging the use of single rooms. There are no special suggestions with reference to the rural population in the Highlands owing to the intention of the Government to legislate on the question of land tenure, but it is recommended that an improved system of local government should be established in the extra-urban parts of Scotland, and that the local authorities should be elected by the ratepayers.

MILK INFECTION.

The failure of a recent prosecution at Paisley, under the Dairies, Cowsheds, and Milkshops Order, deserves notice, inasmuch as it shows the insufficiency of this Order to protect the public against infectious disease conveyed by milk. We learn from the *Glasgow Medical Journal* that scarlet fever broke out among the drinkers of milk from a dairy at Paisley. A child of the dairyman suffering from scarlet fever had been kept at home, and subsequently two other children of the same family had become infected; the dairyman and his wife at this period milking the cows and serving out the milk. A prosecution was instituted, and it was brought out in evidence that the dairyman and his wife visited the children—a servant stating that her mistress "attended" them; but on behalf of the defendants the children stated that their parents did not "touch" them. The prosecution failed on the point that *contact* was necessary for the purpose of conviction. The order has evidently been drawn by someone who is ignorant of the nature of infection, and its early amendment in this and other respects is urgently needed in the interests of the public health.

THE AMERICAN MEDICAL ASSOCIATION AND THE INTERNATIONAL MEDICAL CONGRESS.

AT its meeting in 1884, the American Medical Association appointed a committee of seven gentlemen to present an invitation to the International Medical Congress at Copenhagen to hold its next meeting in Washington in 1887. As our readers are aware, this invitation was accepted; and the committee, desiring to advance all the arrangements for the meeting, and believing itself to be empowered to do so, proceeded to nominate the chief officers and to conduct the preliminary negotiations. Unfortunately, it seems that in so doing they have excited certain local jealousies; and at the late meeting of the Association in New Orleans their action was discussed and condemned, and a resolution was passed electing a committee, consisting of the seven gentlemen previously appointed and thirty-eight others, "one from each State and territory," who should "proceed at once to review, alter, and amend the action of the present committee as it may deem best." From the reports of the discussion we gather that some members of the Association consider that the appointments in the Congress should be filled up on a geographical basis, each State being considered as a distinct entity to be represented. We trust, however, that the new committee will take a wider and more enlightened view than that, and will make the appointments solely in reference to the merits of the various nominees and the degree to which they possess the confidence of the profession in the United States, as a whole, and in Europe. We may be permitted to assure our American brethren that visitors from Europe will in a large measure judge of the position and character of the profession in the States by the scientific eminence of those whom they choose as their prominent representatives. We trust that all difficulties such as we have hinted at will be wisely and amicably surmounted, and that the meeting of the Congress in Washington will be as signal in its success as a scientific gathering and in its display of true cosmopolitan brotherliness, as any previous one.

MEDICAL MISSION WORK IN CHINA.

FROM the recently issued report for 1884 of the Mission Hospital and Dispensary at Chin-Chew in connexion with the Presbyterian Church in England, it appears that ague, anæmia, dyspepsia, leprosy, and diseases of the eye formed a large proportion of the cases coming for treatment. The whole of the region in which the institution is situated is malarious, but some of the districts markedly so. The quartan variety of intermittent fever was by far the most frequently met with. In the treatment of ague the cinchona febrifuge prepared by the Indian Government has been very largely and successfully used, and only in one or two cases was it known to give rise to irritation of the stomach. The cinchona tree could doubtless be cultivated in many parts of China, and it would be a good thing for the people if the Chinese Government should take steps for its introduction and cultivation in the country. Various circumstances occurred during the year that tended to keep down the number of patients as compared with former years—the principal one being the prevalence of cholera, which broke out in the city in September, 1883, remained in an endemic form during the winter and spring months, and assumed an epidemic form about the beginning of July, 1884. In September the daily death-rate was very high; and the people, becoming much alarmed, left the city in great numbers. In the early part of this month the disease seemed to have taken on a very much more virulent type, and many of the cases were cut off in a few hours after the first symptom of diarrhœa appeared. The Chinese estimated that there were about 3000 deaths from cholera in the city. In October and November the cholera was followed by a form of continued fever, which also in many cases was fatal. This fever had many of the leading features of typhus—the temperature, the eruption, and the constipated condition of the bowels all pointed to typhus. The want of more accommodation for in-patients was very much felt during the year, but, as Dr. Grant observes, in the present unsettled state of the country it would be imprudent to take any active measures towards securing larger premises. The work which is being accomplished by this mission is a great and good one, and in course of time, as the hospital and its advantages become better known, it will be less difficult to get more suitable premises.

COCAINISATION OF THE BLADDER.

DR. P. BRUNS of Tübingen records (*Berl. Klin. Woch.*, No. 21) a case of litholapaxy in which the bladder and urethra had been rendered insensitive by cocaine. The patient had suffered from symptoms of stone for four years, and, on sounding, the stone was found to be hard and rough, and two centimetres and a half in diameter. There was also considerable purulent cystitis. As a preliminary measure the bladder was washed out with boro-salicylate solution; then twenty grammes of a 2 per cent. solution of cocaine were injected into the bladder, and ten grammes into the urethra. By shifting the position of the patient the contact of the injection with all sides of the bladder was ensured. After a few minutes' interval the bladder was filled with the boro-salicylate solution, and the operation proceeded with. Owing to the hardness of the calculus thirty-three crushings were necessary, occupying twenty-two minutes; but during the whole period no pain was felt, although previously the patient had hardly borne the passage of a catheter. During the evacuation pain was experienced each time the bladder was distended, but the anæsthesia had lasted for half an hour. Finally, a small quantity of a 10 per cent. iodoform glycerine solution was injected, with the view of protecting the abraded bladder from purulent absorption. The calculus, which was of the oxalate mulberry variety, weighed four grammes. A speedy recovery ensued.

"THE STRANGE STORY."

IT does not, we confess, strike us as strange that any young woman should out of her disordered or disturbed inner consciousness evolve a story which startles the public. Such stories are certainly not strange in the sense of being rare. They are common-place incidents in the lives of many otherwise estimable females. The most recent specimen of this class is put out of consideration on two sides. First, it is improbable to the extent of being almost impossible that an insensible person could have been publicly moved without the fact being known to somebody who would come forward and bear testimony; and we do not think the narrative is free from contradictions too destructive to be either tolerated or explained.

BARBED WIRES.

SOME time ago our columns contained an annotation, pointing out the dangers likely to arise from the use of barbed wire fencing. What we foretold is fully borne out by the statement in an Inverness contemporary, that much indignation is felt in the Dornoch district at the erection of barbed wire fences close to the public road. Two carriage accidents have recently occurred on a part of the road fenced by this wire. In both cases the horses were seriously cut by the barbs, and one of the animals has since died from the injuries thus sustained. The men in charge were also more or less injured, one of them having the palm of his hand badly torn.

MEDICAL SERVICE IN THE SOUDAN.

We have read with much satisfaction the account given by the special correspondent of the *Daily Telegraph* of the work done by the medical officers of the late campaign in the Valley of the Nile. He has given an animated and interesting description of the work as he saw it in the advance south of Wady Halfa, and in the severe engagements at Abu Klea and Abu Kru. He bears testimony to the completeness of the provision made by the head of the department for the care of the sick and wounded, and to the ability with which the arrangements were carried out by the officers in charge of the service in the Soudan. He has done a good service to the medical staff by giving a graphic account of the difficulties they experienced and the dangers to which they were exposed in the discharge of their arduous and important duties; of the cool, quiet, and methodical manner in which these were performed, and of the courage displayed in affording aid to the wounded upon the field regardless of risk and danger. "Trying as oftentimes is the situation of a medical man in civilised warfare, it is as nothing compared with the risk, responsibility, and labour devolving upon him when the contest is waged against a ferocious and savage enemy. In such a position he renders services that can scarcely be overrated." The details given of the work done by the medical officers are interesting as "a tale of forethought, diligence, capacity, and courage." The description of the services thus rendered by the medical staff affords important evidence of the value of the present organisation of the department. The correspondent states that "in equipment and supplies no department of the army was more fully provided, and ahead in all details, or better prepared to cope with work than the Medical Department"; the results were so satisfactory that he heard expressions of dissatisfaction only on two occasions, and in both instances from men who got "neither credence nor consolation for certain alleged ailments they had sought to get treated for." We trust that, although from a military and political point of view the campaign has been a failure, the labours of Surgeon-General O'Nial and the medical staff will not be overlooked, but that they may receive some appropriate recognition of the able, energetic, and satisfactory manner in which they have discharged their onerous professional duties.

PUERPERAL FEVER IN BOMBAY.

It is no exaggeration to say that during 1884 puerperal fever was a household topic among the Parsees in Bombay. The causes of the epidemic are very fully examined and discussed in a paper on the subject read by Dr. Temulji before the Grant College Medical Society. The fever seems to be more prevalent in the hot months of the year, especially before the rain sets in. This may be accounted for by the unsatisfactory state of the drains of the several parts of the city, their stagnation at different points, and the foul emanations therefrom due to extreme solar heat. Puerperal fever is not so prevalent amongst the other sections of the native community as among the Parsees, and the reasons for this are obvious. The Parsees, from false prejudices, get their women delivered on the ground floor, in many cases in a room set apart for the purpose, which as a rule is the worst part of the house, with drains either underneath or passing by the side, and the sewer air freely escaping into every part of the room; and this perhaps is concentrated on account of the doors and windows being closed for fear of the patient catching cold. Another fertile cause of this fever is the bedding which the Parsee ladies use during accouchement. After the forty days are over, they give away all their clothing and bedding to the Bhangees or Halalcores, who, looking upon them as a source of profit, sell the same without the least thought of disinfecting them. From the cotton of the beddings thus given away new ones are made and sold, which are bought by many of the Parsee ladies either for themselves or for their female attendants for use during confinement. The last, though not the least, important cause is, probably, the low vital stamina of the Parsee girl of the present period, the result probably of evils usually accompanying a higher civilisation. Want of exercise is, no doubt, a prime factor in the physical deterioration of the Parsee girls of this generation; they are disposed to lead a more easy life than their mothers and grandmothers did, and consequently they are incapacitated for severe bodily exertion.

THE UNIVERSITY OF LONDON.

We understand that the Special Committee appointed by the Sub-Committee of Convocation have agreed on a draft report, recommending the gradual abolition of life-senatorships, the direct representation of the colleges and large teaching bodies, and the formation of Boards of Studies for the regulation of examinations. The reforms which we have so often urged will therefore be soon brought authoritatively before the University, and they, to a very great extent, coincide with the bases suggested by the promoters of the Teaching University movement.

THE EXAMINATION IN ELEMENTARY ANATOMY AND PHYSIOLOGY.

One of the most interesting features of the English conjoint examination scheme is the examination at the end of the first year in elementary anatomy and physiology. We understand the number of candidates was 363. Of these, 340 passed in anatomy and 23 were rejected. In physiology 320 passed and 43 were rejected. We expect great good from students being required at the end of the first year to give a slight account of their stewardship.

THE LAW AS TO DUSTBINS.

The owner of a dustbin calls attention in a daily newspaper this week to the unfortunate position in which the householder is placed in having no immediate remedy when the parish officials neglect to remove his house dust and refuse. In point of law his dust does not belong to himself but is the property of the contractor, who alone has the right to remove it. If he were, with his neighbours, to make application to the magistrate for a summons against the contractor as the person by whose act or default a nuisance is committed, it would be easy to plead in defence that the dustbin should receive only dry material ashes, &c., and that the nuisance is really created by the houseowner himself in putting into the dustbin vegetable and animal matter, which ought to have been burnt upon the kitchen fire. After all has been said there is a remedy in the hands of the owner of the dustbin, and one far more effectual than that of complaining to a magistrate or the public. If he will exercise his powers as a ratepayer to see that proper persons are returned as vestrymen he would soon have no further ground for dissatisfaction.

THE NUDE.

The protest of "A British Matron" may have been wild and uncalled for. All the same, it is, beyond question and wholly apart from a fastidious taste, perfectly true that no inconsiderable proportion of the Art of the day appeals—intentionally—to a passion which, however cultured it may be, is not exclusively intellectual in its conception of the beautiful. It is idle to pretend that a purely Platonic love of the exquisite and refined, in colour and form, attracts the gaze f thousands to the increasing multitude of pictures repre-enting the female form unclothed. The truth is, we in ngland are too much influenced by the French type of rtistic taste and enterprise. Lady Godivas and Surprised Bathers have been becoming increasingly numerous of ate. By all means let those who like such pictures employ rtists to paint them. This is a free country. It is not, how-ver, necessary, nor, we think, desirable, to crowd the walls of our few public picture galleries with this parade of the beautiful. When, in the cycle of fashionable progress, the time comes for our women to appear in ordinary life as they are portrayed on these equivocal canvases, the latter will cease to be outrageous because they will have become commonplace.

THE PORT SANITARY AUTHORITY AND INFECTIOUS DISEASES.

REGULATIONS made by the Port Sanitary Authority for the Port of London, and approved by the Local Government Board, for the removal to hospital of persons, brought within the port by any ship, who are infected with a dangerous infectious disorder, have just been issued. By their provisions the master of every vessel is bound to report any case of infectious disease to the medical officer at Gravesend, and to remove the patient to hospital there under his supervision. The expression "dangerous infectious disorder" is explained to mean any of the following diseases: cholera, diphtheria, erysipelas, measles, scarlatina, small-pox, typhoid or enteric fever, typhus fever. A penalty is incurred for non-compliance with these regulations.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

THERE seems every probability of an outbreak of epidemic cerebro-spinal meningitis in Berlin; for within the last few weeks Professor Senator has had under his care at the Charité Hospital three cases in quick succession, and he has seen four other cases in consultation.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of April, it appears that the Thames water distributed by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies, contained in every case less organic matter than in the previous month's samples, the improvement being most marked in the case of the West Middlesex and Chelsea Companies' waters. The water drawn from the Lea and delivered by the New River and East London Companies also exhibited a considerable improvement as regards organic matter, the amount of the latter being less than in any of the Thames waters. All the waters were clear and bright on delivery.

AT a meeting of the Council of the Queen's College, Birmingham, held on the 21st inst., Dr. James Sawyer, F.R.C.P., Senior Physician to the Queen's Hospital, was unanimously elected Co-Professor of Medicine as the colleague of Dr. Foster. Dr. Rickards, Physician to the General Hospital, and Dr. Carter, Physician to the Queen's Hospital, were elected Co-Professors of Materia Medica and Therapeutics in succession to Dr. Sawyer.

THE *Crofter* this week gives a portrait and short sketch of the professional and political career of Roderick Macdonald, M.D., F.R.C.S.E., whose name has become familiar [illegible] as a Parliamentary candidate for Ross-[illegible], and as leader in the movement to secure for the crofters representation in Parliament as the only satisfac-[illegible] of redressing their wrongs and grievances.

TYPHUS fever is reported to have assumed a serious form at Massowah. Some cases appeared at the end of April, but there were no deaths until the 24th of that month. Since then the temperature has risen rapidly, the heat becoming terrible, and the epidemic has made many fresh victims. In four days the Italian expeditionary force lost four officers, and the deaths of ten soldiers occurred in three days.

IT is understood that Professor Huxley will shortly resign his Inspectorship of Salmon Fisheries. Among those spoken of as his probable successor are Mr. Francis Day, Mr. Cholmondeley Pennell, and Professor Ray Lankester. We have no reason for apprehending that, if his resignation be tendered, it is owing to any serious impairment of his health.

DR. E. VAN ERMENGEN, who was commissioned by the Belgian Government to proceed to Marseilles in order to inquire into the epidemic of cholera there last year, has published an elaborate report containing the results of his investigation. We shall deal with this important document fully next week.

ON the 26th inst. the death occurred at Manchester of Dr. John Thorburn, Professor of Obstetric Medicine at Owens College, at the age of fifty-one. Dr. Thorburn also held the post of Obstetric Physician to the Manchester Royal Infirmary.

THE SANITARY CONFERENCE AT ROME.

AFTER oft-repeated delays the International Sanitary Conference of 1885 has at last been opened at Rome. On the 20th inst. the delegates were introduced by their several ambassadors to Signor Mancini, Minister for Foreign Affairs, and the inaugural address was then delivered by the Minister, who spoke as follows:—

"Gentlemen, I am proud that the choice of offering you a hearty welcome has fallen upon me. His Majesty the King, my august Sovereign, has charged me to convey to you the great satisfaction he feels at the friendly and sympathetic reception with which Italy's proposal for the assembling of this Conference has been received in all parts of the world. His Majesty is rejoiced to see in his capital representatives of all Governments, assembled in order to fulfil the mission of studying and resolving one of the most important problems with which modern civilisation is at present occupied—namely, the preservation of human life. We took the initiative in this matter immediately after the reappearance on the banks of the Nile, in 1883, of that terrible plague which had already so many times ravaged Europe. Your presence here is the best augury for the success of the work you have undertaken. For the first time since sanitary questions commenced to form the subject of international debates, the assembly which will now take up the study once more sees in the midst of the eminent men of which it is composed both men who are learned and specially fitted for their task by reason of their scientific competence and their long experience, and also those who, being accredited to the Government of his Majesty the King, have a claim to speak on behalf of their several countries. It is for you, gentlemen, to arrange the order of your proceedings; but whatever may be your decision in this matter, I think that the Conference, while discarding as much as possible mere theoretical discussions, and thus giving to its labours an essentially practical character, may well hold a double object in view. I feel that it is above all things important to establish between the several Governments some agreement which shall form the basis on which they may, in their respective countries, establish such measures of prevention, surveillance, and isolation as are necessary in order to deal with this plague at its source, and, as far as possible, to prevent its development. But since, notwithstanding such precautions as it may be possible to take, the disease may threaten to diffuse itself, it will be necessary, in view of such a contingency, to endeavour also to come to some understanding as to the adoption in the several countries of some system of defence against the invasion and diffusion of the disease, which, without laying burdens which are excessive and rarely efficacious on the freedom of communication and commerce, shall be rational and at the same time of practical utility. Gentlemen, your duty will be no less difficult than it is important. But if your efforts, as I venture to hope, are not barren of results, and if the conclusions to which you come, being accepted by your respective Governments, should be embodied in an international convention, you will have the right to congratulate yourselves, and will have deserved the gratitude of the whole human family. Far beyond the mere prestige of power and the splendour of victories, it is those services which are rendered to humanity and to civilisation that take the highest rank in the annals of the world. They stand as the purest and most legitimate of all the titles of nobility which occupy a place in the history of peoples. I trust and hope that of such may be the results of this Conference, which I now have the honour to inaugurate, and which I now declare to be open."

The actual labours of the Conference commenced at once by the election of Signor Cadorna, President of the Council, as President of the Conference. Certain preliminaries as to the proceedings and debates were also provisionally agreed upon, and the Conference adjourned until Friday, the 22nd inst., when it was hoped that all the foreign delegates would have arrived. With a view of facilitating the labours of the Conference, the medical delegates were, on the second day of meeting, formed into a technical commission, which will discuss the various decisions arrived at by the Vienna Conference of 1874, and which will then submit the conclusions they arrive at to the Conference as a whole.

As far as can be judged from Signor Mancini's inaugural address, and from the *personnel* of the Conference, it is evident that there will be a determined effort on the part of many to maintain quarantine by sea, although perhaps under somewhat less onerous conditions than heretofore. England, as is well known, will never again impose this antiquated restriction against cholera, and it is to be hoped that the British delegates may succeed in showing their *confrères* that our present system of medical inspection and isolation, coupled with a progressive improvement in the general sanitary circumstances of the kingdom, is the only system which is at the same time rational and capable of efficient execution. We must, however, not be too hopeful in this matter; the realisation of which will be the more improbable if we again find ourselves this summer face to face with an extending cholera epidemic. Panic will then doubtless once more reign supreme.

So far, however, the Technical Commission has done good work, having inaugurated its sittings by a vote which, with the exception of Turkey alone, recorded with unanimity a condemnation of quarantine measures by land. The lesson of 1884 has not therefore been altogether without its results, and is is to be hoped that this decision will be ratified by the Conference as a whole, and that it will lead to the adoption of those measures of sanitary improvement which afford the greatest obstacle against the spread of cholera.

The following are the names of the diplomatic and scientific delegates to the Conference who are now in Rome. One or two minor States whose delegates have not arrived may be represented later on:—

Argentine Republic: M. del Viso (Minister Plenipotentiary). *Austro-Hungary:* Count Ludolf (Austrian Ambassador), Dr. de Hofmann, Dr. Grosz, Count Batthyanyi. *Belgium:* M. Van Loo (Minister Plenipotentiary). *Brazil:* M. Callado (Minister Plenipotentiary), Dr. d'Azambuja. *Chili:* M. Matta (Minister Plenipotentiary). *China:* General Tcheng-Ki-tong. *Denmark:* M. de Hegermann Lindencrone (Minister Plenipotentiary). *France:* M. Decrais (French Ambassador), Dr. Proust. *Germany:* M. de Keudell (German Ambassador), Dr. Koch, Dr. Erhardt. *Great Britain:* Sir J. Savile Lumley (British Ambassador), Sir Guyer Hunter, Dr. Thorne Thorne. *Greece:* M. Rhasis (Minister Plenipotentiary). *Guatemala:* M. Segarini (Consul-General). *India (British):* Sir Joseph Fayrer, Dr. T. Lewis. *Italy:* M. Cadorna, President of the Council of State (President of the Conference), Dr. Baccelli, Dr. Moleschott (President of the Technical Commission of the Conference), Dr. Semmola, Dr. Buonomo, Naval Commander Randaccio, M. Casanova, M. Scibona. *Japan:* M. Tanaka (Minister Plenipotentiary), M. Nagay. *Mexico:* M. Sanchez Azcona (Resident Minister), Dr. Hijar y Haro. *Netherlands:* M. de Westenberg (Minister Plenipotentiary), Dr. Ruysch. *Peru:* M. Brunialti. *Portugal:* M. de Carvalho e Vasconcellos (Minister Plenipotentiary), Dr. Da Silva Amado. *Roumania:* M. Obédénnare (Minister Plenipotentiary). *Russia:* Baron d'Uxkull Gyllenband (Russian Ambassador), Dr. Eck. *Servia:* M. Franassovich, Dr. Danitch. *Sweden and Norway:* M. Linstrand (Minister Plenipotentiary), Professor Bergman, Dr. Dahl. *Switzerland:* M. Bairer (Minister Plenipotentiary), Dr. Reali, Dr. Sonderegger. *Turkey:* Mihrau Effendi (Chargé d'Affaires), Dr. Zoéros Pacha. *Uruguay:* M. Antonini y Diez (Minister Plenipotentiary).

THE MEDICAL AND CHIRURGICAL SOCIETY OF JAPAN.

AMONGST the many recent advances made by the Japanese in the adoption of European institutions that which relates to medical science is not the least significant. Two years ago we had the pleasure to notice a promising medical journal, the *I Ji Shimbun*, which still receives the support of those for whom it was intended; and we have now to record the success of an Association, the Sei I Kwai, established on the basis of the London Royal Medical and Chirurgical Society, for the advancement of medical science in Japan.

The Sei I Kwai, which issued its thirty-sixth monthly Fasciculus of Transactions in January last, numbers eighty-six members, including nearly all the leading representatives of the profession in Tokio, and some of the principal foreign practitioners, and is under the presidency of Mr. K. Takaki, F.R.C.S., the Director-General of the Naval Medical Department, formerly a distinguished pupil of St. Thomas's Hospital. Its business is conducted at weekly ordinary meetings, when cases are brought forward and discussed in due form, papers are read, and points of interest in foreign journals are quoted and commented upon; and at special monthly meetings held for the more systematic discussion of subjects previously announced.

The January and February numbers of the Transactions now before us present a courageous innovation, the addition of a supplement in which certain of the contents appear in English form and so become available for use and criticism by the outside world. In the January part the supplement is introduced by a report of Four Cases of Ovariotomy performed under complete Antiseptic Precautions by Mr. Takaki, with the result of three successes against one death, the fatal termination being due to shock and hæmorrhage induced by the removal of an extensively adherent tumour of very large dimensions.

Mr. Furukawa Sakayé follows with an interesting paper on Japanese Cosmetics. We learn from this that the use of the toilet adjunct in question, which is confined to women and actors, commenced as early as 724 A.D. The main ingredient, according to the analysis of Professor Atkinson (Trans. As. Society of Japan, vol. vii.), is carbonate of lead diluted with powdered rice starch. No charge of poisoning has ever been raised against the composition; but, on the other hand, it is supposed to exert a wonderful curative influence upon certain skin diseases, which Mr. Furukawa Sakayé unfortunately omits to name.

A report by the Central Sanitary Bureau of cases of Poisoning collected from the various provinces during the half-year ending June, 1884, is next quoted, and it appears that of a total of 132 instances recorded seventy resulted from eating poisonous fish, forty, with twenty-three deaths, being set to the score of the tetradon. The subject of tetradon poisoning is discussed in a subsequent paper.

A statistical table to show the prevalence of Myopia amongst the students of the Agricultural College at Sapporo in Yezo is contributed by Dr. J. C. Cutler, and states that of the pupils (whose total number is not mentioned) entering the College 29·5 per cent. were already myopic, and that an additional percentage of 23 developed the complaint after admission. As a reading people the Japanese have always suffered from myopia, but there is reason to hope that in the future its frequency may be diminished by improvements in printing, and an increased knowledge of the bearing of properly constructed desks &c. in schools upon the question of visual defects.

In the February number Dr. Osawa writes an account (translated by Mr. Tsuruda) of Tetradon Poisoning, the frequency and fatality of which have already been referred to. From this it appears that three-fourths of the twenty known varieties of the fish are found to be more or less poisonous; that the intensity of the virus increases in certain seasons, notably during the period of gestation in the month of April; that the poisonous principle is located in the ova, and sometimes in the liver also, the flesh being innocuous; and that it is active during the life of the fish, and does not develop as in the bonito and other members of the tribe as a result of post-mortem changes. The poison is described as a crystalloid, readily diffusible from the tissues into water, slightly soluble in ether, chloroform, and spirit, and susceptible of preservation for a considerable period (two months in the case of the eggs of the T. chrysops). It is said to kill by asphyxia. The writer concludes an able paper with the pithy assurance that "the only prophylactic against poisoning by the fish is to avoid eating it."

A report of the Diseases and Injuries of the Mariners in the Japanese Navy during the year 1883 presents the noteworthy feature that out of a total of 2335 cases registered under the head of general diseases, no less than 1292, with a mortality of 3·75 per cent., were due to "kakké," a disease probably of malarious origin, which appears to be identical with the beriberi of India.

The number closes with a translation of an imperial decree relating to the Licensing of Medical Practitioners in Japan. These regulations having necessarily been constructed with reference to the present stage of transition in medical education, must undergo considerable modification as time and knowledge progress; but they are well adapted for existing circumstances, and framed in a spirit of indulgence that should leave no grounds for complaint from candidates who desire to assume the grave responsibilities of the physician.

THE HEALTH OF IRELAND IN 1884.

THE General Abstract recently issued by the Registrar-General of Ireland affords valuable statistical evidence of the health condition of that portion of the United Kingdom during last year. It appears that, though the excess of births over deaths was 31,631, the population decreased 44,232 during the year, owing to the emigration of 75,863 persons. The population of the country has declined year by year since 1877, when there was a slight reaction from previous decline, and was estimated to be 4,962,570 in the middle of last year. The marriage-rate showed an increase last year, and was higher than in any year since 1878, indicating a tendency to revival of prosperity. The birth-rate, too, was slightly higher than in 1883, and equal to 24·0 per 1000, but was 1·2 below the mean rate in the preceding ten years. The death-rate was 17·6 per 1000, against 17·4 and 19·2 in the preceding two years, and was 0·8 below the mean rate in the ten years 1874-83. The marriage-, birth-, and death-rates in Ireland are all very considerably below those prevailing either in England or Scotland, with which, however, they are not comparable, owing to the abnormal age proportions of the Irish population. The constantly large amount of emigration from Ireland during a long series of years has depleted the population of that country of so large a proportion of its young adults that the marriage- and birth-rates are necessarily reduced. The unduly small proportion of children and young adults necessarily affects the gross death-rate, and destroys its value for comparative purposes, unless due correction be made for exceptional age distribution of the population; but such correction is not made by the Registrar-General for Ireland. The Irish General Abstract now under notice gives, however, much more information than the corresponding General Abstract for England and Wales, which gives only bare facts, without any calculated rates. The deaths referred to the principal zymotic diseases in Ireland last year were equal to 8·2 per cent. of the total deaths, and to a rate of only 1·45 per 1000 of the estimated population, which was 0·49 below the mean annual rate from the same diseases in the preceding ten years. Only one death was referred to small-pox during the year. The zymotic death-rate in Ireland last year was little more than half the rate from the same diseases in England and Wales, but this may to some extent be attributed to the small proportion of children in the Irish population, as children under ten years of age are invariably the greatest sufferers from zymotic diseases. One of the most useful features in this Irish return is one which we should much like also to see in the English return; this is the death-rate in each of the urban sanitary districts. The defect in this table is that the rates in 1884 are calculated upon the enumerated population in 1881; the rates, therefore, for the whole of Ireland in this table differ considerably from those given in other tables. All the rates in this table are more or less understated in consequence of the decline that has taken place in the Irish population since 1881. However, the rates respectively given for the urban and rural sanitary districts are interesting, although they require correction for difference of age distribution, as well as for the want of duly estimated populations. The urban birth-rate is given as 29·4, while in the rural districts it did not exceed 21·4. The death-rate was 24·7 in the urban and only 14·9 in the rural districts; and the zymotic rate, which was 2·8 in the urban districts, did not exceed 1·0 in the remaining or rural districts. Excluding the smallest towns, the highest death-rates in the Irish urban sanitary districts during last year were 26·3 in Limerick, 26·7 in Cork, and 29·8 in Waterford. It is doubtful, however, how these rates would have been affected if they had been calculated upon the estimated population in the middle of 1884, instead of upon the enumerated population in 1881. The statistics of infant mortality in Ireland are exceptionally favourable. The deaths under one year of age last year did not exceed 92·5 per 1000 of the registered births in Ireland, whereas the proportion in England was equal to 147 per 1000. Whether viewed as a test of sanitary condition or of care of infant life, this low rate of infant mortality in Ireland is eminently satisfactory.

WILLS OF MEDICAL MEN.

THE will and two codicils of Mr. John Mann, formerly of 4, Charterhouse-square, surgeon, but late of Warltersville-road, Hornsey-rise, and of Moreton-in-the-Marsh, Gloucestershire, who died on January 11th last, were proved on the 1st ult. by Mrs. Mary Mann, the widow, and Mr. George Loosely, the acting executors, the value of the personal estate amounting to over £18,000. There are gifts to his wife, to each of his four children, and to his executor, Mr. Loosely; and as to the residue of his property, the testator leaves two-fifths to his daughter, Elizabeth Frances, and one-fifth each to his children, Joseph Procter, Mary Rebecca, and Edith Spear.

The will and two codicils of William Bruce Joy, M.D., F.C.P. in Ireland, late of 16, Pembridge-gardens, Bayswater, who died on January 28th last, have been proved by Mr. Albert Bruce Joy and Mr. George William Joy, the sons, the executors, the value of the personal estate exceeding £2400. The testator leaves to his wife, Mrs. Arminella Joy, all his furniture and effects, cash in the house and at his bankers, and an annuity of £300; to his son, Archibald Edward, an annuity of £250; and to Frederick James McDonnell, £100. Subject to the foregoing, he leaves his estate of "Joy's reclaimed Dam," Belfast, and his other estates in Ireland with the residue of his real and personal property as to two-thirds for his son, Albert Bruce, and as to one-third for his son, George William.

The Irish probate granted at Dublin of the will of Samuel Warren, M.D., late of Hoylake, Cheshire, and of 83, Grosvenor-square, Rathmines, Dublin, who died on Feb. 12th last, to Mrs. Frances Elizabeth Warren, the widow and sole executrix, has been resealed in London, the value of the personal estate in England and Ireland exceeding £1500. The testator gives, devises, and bequeaths all the real and personal estate which he shall die seized or possessed of to his wife absolutely.

The following legacies have recently been left to Hospitals and other medical charities:—Mr. Francis Parsons, of Ashford House, Hornsey, £500 each to St. Albans Dispensary and the Hemel Hempstead Infirmary.—Mr. Stephen Cooke, of Buckingham, £300 to the Cancer Hospital, Brompton; £200 to the Horton Infirmary, Banbury; and £100 each to St. Bartholomew's Hospital, Guy's Hospital, the Hospital for Women and Children, Vincent-square, Westminster, the new Hospital for Women, Marylebone-road, the Hospital for Consumption and Diseases of the Chest, Brompton, the Royal Hospital for Diseases of the Chest, City-road, the National Hospital for Paralysis and Epilepsy, Queen-square, Bloomsbury, the Royal London Ophthalmic Hospital, Blomfield-street, Moorfields, St. Peter's Hospital, Henrietta-street, and the Buckingham Nursing Hospital.—Mr. Robert Barbour, formerly of Manchester but late of Bolesworth Castle, Cheshire, £500 to the Chester General Infirmary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Registration District of Bedwelty.—Mr. John Spear has recently re-inspected the urban sanitary districts of Ebbw Vale and Abertillery, and the rural sanitary district of Bedwelty, comprising the above area. He reports, with regard to the Ebbw Vale district, that a sewer has been laid at Cwm and another is in course of construction at Wainellwyd. At Chapeltown a plan for sewerage has been approved by the authority, and for Briery Hill plans are in course of preparation. It is proposed to defray the cost of these works out of the current rates, and the work will therefore be proceeded with very slowly. It is also intended that the sewage, unpurified, should be discharged into the Ebbw, a course to be deprecated. There has been considerable improvement since Mr. Spear's previous visit in 1882 in the matter of both privy accommodation and scavenging. New houses are now supplied with a closet of the Manchester pattern, and the pails are regularly emptied; but there are still some 2300 houses either without privy accommodation or with a provision of the worst kind. There is, however, no change in the water-supply, but there is some improvement in house construction. Mr. Spear points out methods by which older cottage property might be improved both as regards ventilation and prevention of dampness. Reporting on the Abertillery district, he refers to the prevalence of typhoid fever in 1882, 1883, and 1884, the result of excremental pollution of earth, air, and water. Little, however, had been done but the provision of a small amount of sewerage, and no proper efforts are made to improve the condition of houses.

In the Bedwelty rural district, Mr. Spear states that the sanitary condition of the villages is deplorable; in a few places attempts have been made to provide sewers, and there is a prospect of an improved water-supply, but the building bye-laws are not enforced, and no attempt is made to isolate infectious disease.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hanley Urban District.—On an estimated population exceeding 51,000, the birth-rate was 38·8 and the death-rate 21 per 1000, both rates exhibiting a decrease on the mean of preceding years. The infant mortality also last year showed a decline from the higher rates that obtained in 1882 and 1883, but it was still markedly in excess of the rates prevailing amongst other corresponding urban populations. The rate of death from the seven principal zymotic diseases was also high—namely, 3·6 per 1000, and 73 deaths were registered from diarrhœa and dysentery. Unfortunately the report, professedly relating to the "sanitary condition" of the borough, is little else than a record of statistics, and hence we are unable to judge of the conditions leading to preventable death, or of the advice which has been given in order to improve the state of the district. The action taken by the inspector of nuisances, as tabulated in an appendix, points to efficiency on the part of this officer.

Jarrow (Urban).—The medical officer of this borough in his report for 1884 expresses his belief that the lamentable depression of trade, and consequent distress among the working classes, had an appreciable effect upon the mortality statistics of the year. The population of the borough is estimated at 29,000, showing a higher rate of increase than prevailed between 1871 and 1881; that the population, however is not over-estimated appears probable from the fact that the birth-rate calculated upon the medical officer's estimate was equal to 43·9 per 1000. This rapid increase of population at a time of such heavy depression is a noteworthy fact. The death-rate, after the due addition of the deaths belonging to the borough recorded in the Union Workhouse outside the municipal boundaries, was equal to 23·5 per 1000; and, in spite of a considerable reduction in the mortality from zymotic diseases, showed a slight increase upon the rate in the previous year, and exceeded by 2·2 per 1000 the mean rate in the ten years 1873-82. Dr. Munro considers that there is a close relation between this increase in the death-rate and the existing "bad times," a conclusion supported by the fact that zymotic fatality, other than that due to infantile diarrhœa, had declined. Infant mortality, measured by the proportion of deaths under one year to births, was equal to 163 per 1000, and exceeded that which prevailed in any year since 1878, when the summer was hot and the fatality from infantile diarrhœa excessive, as was the case last year. The deaths from the principal zymotic diseases were equal to 3·8 per 1000 of the estimated population, and showed a considerable decline from the rates in the preceding two years, which were 5·0 and 5·1. It is noted that the annual zymotic death-rate in the borough during the five years 1874-78, before the introduction of the system of compulsory notification of infectious diseases, was 5·7 per 1000, whereas it has declined to 3·8 in the six years since notification was introduced. This is important evidence in favour of notification, although it would not be safe to attribute the decline entirely to this cause. In connexion with this subject it is to be regretted that very little progress appears to have been made during the past year in the provision of permanent hospital accommodation for infectious diseases.

Bedford Urban District.—Dr. Prior reports that Bedford continues to exhibit a very low death-rate, it having been 15 per 1000 last year; the zymotic rate was also only 1·5 per 1000. Diphtheria, which some years since prevailed so very widely, is still troublesome, but it is mainly confined to a comparatively small portion of the town lying south of the river. The various conditions, such as dampness, states of sewers and drains, &c., which might account for this localisation of the affection, have been carefully considered, and Dr. Prior is inclined to think that, after all, the circumstance is really due to the propagation of the disease by means of a series of mild and unrecognised cases in this special locality.

Willesden Urban District.—This district has now a population of over 36,000, and last year it achieved, notwithstanding its rapid increase of inhabitants, the end of attaining the smallest death-rate on record—namely, 14·6 per 1000. There was some increase in the amount of zymotic disease, but this was mainly due to a prevalence of whooping-cough, a disease against the spread of which no practical measures of prevention can as yet be regarded as available. Owing to a prevalence of small-pox, and to the failure of the authority to prepare themselves with proper means of isolation, hospital tents were procured, and subject to infectious disease not making its appearance at an unsuitable time of the year, the tents may be regarded as still available. An ambulance is very much needed, there being no proper means for the removal of patients. Dr. Branthwaite also suggests a chair for carrying the sick downstairs, but nowadays every proper ambulance is fitted with a movable stretcher which the patient is laid on in his bedroom, which is then made to slide into the ambulance, and on which he is carried from the ambulance to the hospital bed. If the recumbent position be unnecessary, the stretchers can always be so adapted as to suit other positions.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5443 births and 3594 deaths were registered during the week ending the 23rd inst. The annual death-rate in these towns, which had been equal to 20·2 and 20·4 per 1000 in the preceding two weeks, further rose last week to 21·1. During the first seven weeks of the current quarter the death-rate in these towns averaged 22·1 per 1000, against 23·0 in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 13·3 in Bolton, 17·3 in Bradford, 17·5 in Halifax, and 18·0 in Leicester. The rates in the other towns ranged upwards to 29·1 in Manchester, 30·0 in Newcastle-upon-Tyne, 30·1 in Preston, and 31·5 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 481 and 463 in the previous two weeks, rose to 510 last week, and included 182 from measles, 158 from whooping-cough, 42 from diarrhœa, 40 from scarlet fever, 37 from "fever" (principally enteric), 34 from small-pox, and 17 from diphtheria. No death from any of these principal zymotic diseases was returned last week in Derby, whereas they caused the highest death-rates in Birkenhead, Blackburn, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Liverpool, Birkenhead, and Newcastle-upon-Tyne; from whooping-cough in Oldham, Plymouth, and Blackburn; from scarlet fever in Wolverhampton; and from "fever" in Cardiff and Norwich. The 17 deaths from diphtheria in the twenty-eight towns included 10 in London and 2 in Preston. Small-pox caused 66 deaths in London and its outer ring of suburban districts, exclusive of 22 deaths of London residents recorded in the hospital ships and camp at Darenth; also 2 in Manchester, 2 in Sheffield, 1 in Hull, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1282, 1361, and 1364 on the preceding three Saturdays, further rose to 1374 at the end of last week; the admissions, which had been 315 and 211 in the previous two weeks, rose again to 282 last week. The Highgate Small-pox Hospital contained 68 patients on Saturday last, 15 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 287 and 291 in the preceding two weeks, further rose last week to 304, and were 5 below the corrected average. The causes of 62, or 1·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Bradford, Preston, and in four smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Halifax, and Bristol.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 20·6 and 23·4 per 1000 in the preceding two weeks, declined again to 21·2 in the week ending the 23rd inst., and was almost identical with the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 10·6 in Leith and 18·0 in Edinburgh, to 22·0 in Paisley and 24·7 in Glasgow. The 517 deaths in the eight towns showed a decline of 53 from the number in the previous week, and included 22 which were referred to whooping-cough, 16 to diarrhœa, 15 to measles, 8 to "fever" (typhus, enteric, or simple), 3 to scarlet fever, 3 to diphtheria, and not one to small-pox; in all, 67 deaths resulted from these principal zymotic diseases, against 55 and 79 in the preceding two weeks. These 67 deaths were equal to an annual rate of 2·7 per 1000, which was 0·3 below the mean rate from the same diseases in the twenty-eight English towns. The 22 deaths from whooping-cough in the eight towns showed a further decline from the numbers in recent weeks, and included 12 in Glasgow, 4 in Dundee, and 3 in Edinburgh. The 16 deaths attributed to diarrhœa were fewer by 3 than those in the previous week, but exceeded the number in the corresponding week of last year by 5. The fatal cases of measles, which had been 13 and 19 in the previous two weeks, declined again to 15 last week, all of which occurred in Glasgow. The 8 deaths referred to "fever" corresponded with the number in the previous week, and included 5 in Glasgow and 3 in Edinburgh. Two of the 3 deaths from scarlet fever, and 2 of the 3 from diphtheria, were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 117 and 93 in the preceding two weeks, rose again to 107 last week, and were 7 above the number returned in the corresponding week of last year. The causes of 76, or nearly 15 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 28·5 and 35·0 per 1000 in the preceding two weeks, declined again to 31·2 in the week ending the 23rd inst. During the first seven weeks of the current quarter the death-rate in the city averaged no less than 32·6 per 1000, the mean rate during the same period not exceeding 20·8 in London and 18·4 in Edinburgh. The 211 deaths in Dublin last week showed a decline of 26 from the number in the previous week, and included 17 which resulted from measles, 6 from "fever," 6 from scarlet fever, 2 from whooping-cough, 1 from diphtheria, 1 from diarrhœa, and not one from small-pox. Thus, 33 deaths resulted from these principal zymotic diseases, against 22 and 34 in the preceding two weeks; these 33 deaths were equal to an annual rate of 4·9 per 1000, the rate from the same diseases last week being 3·1 in London and 1·7 in Edinburgh. The fatal cases of measles in Dublin, which had been 17, 12, and 14 in the preceding three weeks, rose again to 17 last week. The 6 deaths from scarlet fever, and the 6 from "fever" (typhus, enteric, or simple), also exceeded the numbers in recent weeks. The deaths from diarrhœa and whooping-cough, on the other hand, showed a decline. Three inquest cases and 2 deaths from violence were registered within the city; and 63, or nearly a third of the deaths, were recorded in public institutions. The causes of 22, or more than 10 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Amongst the officers who left Sawakin on the 22nd inst. in the *Calabria* was Surgeon P. A. Hayes, and amongst those who left in the *Ganges* on the 27th inst. was Surgeon N. Manders.

The following medical officers have arrived at Cairo, sick, from the Nile:—Surgeon-Major R. W. O'Donnell, and Surgeons R. H. Clements, W. S. Pratt, F. H. Treherne, and H. P. Birch, Medical Staff.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon John Wilson, to the *Cormorant*; Arthur Keess, Esq., M.R.C.S., to be Honorary Surgeon to the Royal Naval Artillery Volunteers (London Brigade).

MILITIA MEDICAL STAFF.—Surgeon-Major Charles Wm. Marriott, 4th Battalion, the Royal Warwickshire Regiment, resigns his commission; also is permitted to retain his rank, and to wear the prescribed uniform on his retirement; Surgeon Herbert Goldingham Budd, 3rd and 4th Battalions, the Worcestershire Regiment, to be Surgeon-Major; Surgeon Duncan McFadyen, 2nd Battalion, the Queen's Own Cameron Highlanders, to be Surgeon-Major; Surgeon James Ramsey, M.D., 3rd Battalion, the Prince of Wales's Own (West Yorkshire Regiment), to be Surgeon-Major.

YEOMANRY CAVALRY.—Cheshire: Surgeon William Chas. Watson resigns his commission.

ARTILLERY VOLUNTEERS.—1st Cinque Ports: Captain Alfred Sparkes resigns his commission; Acting Surgeon Thomas Horne, M.D., resigns his appointment.—1st Worcester: William Herbert Packer, Gent., M.D., to be Acting Surgeon.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Lincolnshire Regiment: Thomas Porter Greenwood, Gent., to be Acting Surgeon.—10th Lanarkshire (Glasgow Highland): Quintin Chalmers, Gent., to be Acting Surgeon.—11th Middlesex (Railway): Isaiah George Butters, Gent., to be Surgeon. 3rd Lancashire: William Deans, Gent., to be Acting Surgeon.—1st Cinque Ports: John James Marshall, Gent., to be Acting Surgeon.

HOSPITAL FOR SICK CHILDREN.—At the thirty-third annual meeting of the governors of this institution on the 20th inst. it was stated that the number of in-patients admitted during the past year was 932, and that the out-patients receiving advice and medicine were 15,270. At the Convalescent Hospital, Highgate, 249 children had been received. The available income amounted to £9844, including legacies to the amount of £1650. The expenditure at both establishments amounted to £11,471, which included a portion of the outlay on alterations.

Correspondence.

"Audi alteram partem."

"PNEUMOTHORAX FOR HÆMOPTYSIS."

To the Editor of The Lancet.

Sir,—My object in trespassing upon your space is not to enter into the important question of the therapeutic value of the mode of treatment advocated by Dr. Cayley in his most interesting communication to the Clinical Society on the above subject, but simply to discuss how far the special method adopted by him is calculated to secure the desired end, the collapse of the lung; and I therefore venture to ask, What reason have we to believe that free incision into the pleural cavity through the chest wall is necessarily followed by collapse of the lung?

Theoretically, the desired result should be attained; when the atmospheric pressure acting through the larynx is neutralised by the pressure of the air upon the outer surface of the lung, the elastic force of the lung should be set at liberty to produce complete collapse of the organ and to restore it to its fœtal condition. "Thus," according to Hermann,[1] "*should, through any opening, air pass into the* space between the lungs and the thoracic walls, then the lungs by virtue of their elasticity collapse to their natural (atelectic) volume (pneumothorax)."

I venture to submit, however, that collapse of lung by no means necessarily follows the free admission of air into the pleural cavity. This has long been fully recognised. Mr. Erichsen, for instance, says,[2] "Collapse of the lung in wounds of the chest consequent upon the action of the atmospheric pressure upon the outside of the organ, has been more frequently spoken about than seen. The chest may be largely opened, and the full pressure of the atmosphere allowed to act on the outer surface of the lung, and yet no collapse of this organ takes place. The lung in such cases may be seen rising and falling at the bottom of the wound." In my own experience this is just what occurs when the thoracic cavity is freely opened in the treatment of empyema; in such a case the lung, provided that it is not bound down by adhesions, may be plainly seen rising and falling during respiration, just as described by Mr. Erichsen in the case of primary wound of the pleural cavity. When the opening is first made, indeed, the violent expulsion of the pus and the irritative cough dependent upon rapid expansion of the lung plainly indicate that what is taking place is the very opposite of collapse of the organ.

If it were a fact that free incision into the pleural cavity necessarily produced collapse of lung, the operation for the cure of empyema would be an exceedingly grave undertaking, on account of its inevitable after-effects. For since, on the one hand, the lung could not expand to meet the chest wall, and thus obliterate the pus cavity, unless the external opening were closed, and, on the other, the abscess cavity could not become obliterated unless the aperture were left open to allow of free drainage, it would of necessity follow that in the large proportion of cases the patients would be left with a lung in a condition of complete and permanent collapse and a chronic fistulous opening into the pleural cavity. It is well known, however, that such a result is not met with except in the most unfavourable cases, when the lung is already bound down by adhesions and the chest wall cannot fall in to the requisite extent.

Collapse, or, more correctly, compression, of lung as the result of pneumothorax occurs with certainty only when the air is pent-up in the pleural cavity; when it enters with inspiration and does not escape with equal freedom during expiration; and it is consequently met with by far the most often when perforation of the cavity occurs from the lung, in the absence of any free external opening; and it is well known that the urgent symptoms produced by such a condition may be at once relieved by thoracentesis, by which procedure the pressure of the air in the pleural cavity is reduced to that of the atmosphere.

A careful consideration of the details of the very important case brought forward by Dr. Cayley shows that the collapse of lung which was actually found post mortem may be explained in accordance with the above theory. For it is noted that during the treatment of the case the tube became blocked and pleurisy with effusion set in. The physical conditions for the induction of compression of lung were thus established.

I would therefore submit that if it is desired to produce collapse or compression of lung, air should be injected into the pleural cavity, as proposed by Mr. R. W. Parker and commended in your remarks upon the subject, rather than admitted by a free external opening, in order that a compressing force greater than that of the atmosphere may be secured, and the collapse of the organ may thereby be rendered certain.—I am, Sir, your obedient servant,

E. Markham Skerritt, M.D.Lond., F.R.C.P.,
Senior Physician to the Bristol General Hospital.
Clifton, May 26th, 1885.

THE TITLE OF "DOCTOR" FOR LONDON MEDICAL STUDENTS.

To the Editor of The Lancet.

Sir,—The proposal of the Royal College of Surgeons to obtain power, in conjunction with the College of Physicians, to grant the title of "Doctor" to their licentiates and members in future must be unitedly opposed by graduates of recognised universities. Granted that there is a commercial value to the title, it would be manifestly unfair to those who have obtained it in a legitimate way to sow it broadcast in this manner. Of course, it is easy to see that it is the unblushing way in which the Licentiates of the Edinburgh and Glasgow Corporations have taken to themselves the title (which it has been proved does not belong to them) which has provoked the above resolution. Surely it is beneath the dignity of our English Colleges to follow in the footsteps of their unworthy compeers! What compensation is to be given to those who have taken the extra trouble and gone to considerable extra expense to gain a university degree in addition to the Membership of the College? Ought not a still higher title to be granted them, or else some distinguishing mark by which the public can gauge the different value of their "Doctorate"? Of course, to the public every medical man, from the lowly L.S.A. to the magnificent F.R.C.P., and consulting physician, is "doctor," in the same way that to the Irish peasantry every military man is "captain." If it be required that all medical men should start with equal degree in rank, baronetcies should be conferred on all, for there is no doubt of the extra commercial value of that title to medical men, and although this distinction has also been gained (by those medical men who hold it) by extra work, zeal, or skill, why should this levelling down process only begin at "doctor"?

Let the Council of the College admit their members to a share in its government, and alter its constitution, if necessary, to allow of this, and they will be doing a great work; but, as a member, I beg to protest against this attempt to destroy the value of university titles gained by those who have taken the extra trouble and work to procure them.

I am, Sir, yours truly,
C. St. John Wright, M.B.Aberd., &c.
St. Mary Infirmary, Islington, May 26th, 1885.

SMALL-POX RISKS AND REVACCINATION.

To the Editor of The Lancet.

Sir,—With reference to Mr. Goude's letter in your issue of the 16th inst., on the above subjects, and the paper read before the Society of Arts on the 8th inst., if you will kindly give me a little space in an early issue I shall be very happy to place before the profession, by means of your columns, the reasons which led me, as Mr. Goude puts it, to "publicly state his [my] disbelief in the necessity for revaccination in adults who have been efficiently vaccinated;" and to prohibit the practice of revaccination in the system of voluntary vaccination inaugurated by me in the first circle of the North-West Provinces in India in 1864. The practical experience and personal observation of thirty years' service in India, the home of small-pox, with the last twenty years of that service, I may say, almost entirely devoted to the subject of ascertaining the best prophylactic for small-pox, have satisfied me that no prophylactic can even approach vaccination; and when it is carefully supervised, and skilfully practised, and the system known as arm-to-arm vaccination, or what really amounts to it.

alone carried on, there is no necessity for revaccination. My opportunities for arriving at any conclusion on this most important subject will, I think, be allowed to be extensive and special, when I state that, during the last twenty years of my Indian service, I have been continuously engaged in vaccination in one sanitary circle, with a population of ten millions and an average of 500 to the square mile—with my vaccine work standing the test of small-pox as an annual visitor—with no attempt at isolation even in sporadic cases; on the contrary, with the promiscuous collection of cases of the disease in every stage of the eruption, with children, as yet free from it, at the shrine of the goddess of small-pox, "Sutla." Here, in the midst of all this small-pox contagion and infection, I have never protected (if I may use the term) my work by revaccinating a single native youth or adult, or permitted one of my two hundred subordinates to do it. If, therefore, revaccination is necessary in this country owing to the prevalence of small-pox among the vaccinated, I can point to towns, cities, and districts where small-pox is practically unknown, except in a few isolated unvaccinated cases, and ask, Why this difference? I will not, however, take up more of your space at present. All I ask from the numerous professional and unprofessional readers of your journal is a hearing and an opportunity of showing that Jenner's great discovery has gained by the lapse of time; and that in India it has by its own merit overcome every possible difficulty, and is gratefully accepted in the place of inoculation by a nation who have practised that prophylactic from time immemorial.

I am, Sir, yours faithfully,
R. PRINGLE, M.D.,
Late Sanitary Department, H.M.'s Bengal Army.

Blackheath, S.E., May 19th, 1885.

THE NEW LUNACY BILL.

To the Editor of THE LANCET.

SIR,—Without venturing an opinion on any of the points touched upon by the Lord Chancellor's new Bill, I would beg to direct your attention to a matter not therein referred to, and which, I think, calls as loudly as any other for reform. I refer to the power at present vested in the magistracy of sending a pauper lunatic to any other asylum in England than that in his own county should there not be room for him in the home establishment. Under this law hundreds of unfortunates are annually conveyed to far distant parts of the country. Their friends are poor, and have neither the time nor the money necessary for their visitation. So pauper lunatics are left in their affliction to mourn their unhappy lot; to live, and probably to die, in the midst of strangers, and to suffer in their declining years that feeling of desertion and utter loneliness which was until now supposed to be reserved for the criminal. The Commissioners in Lunacy expressed their disapproval of the system some years back, saying that it was the cause of very great hardship to the patients so transferred. Could not a clause be inserted in the Bill at present being considered making it compulsory that pauper lunatics should be kept and treated within the counties in which they are chargeable as paupers?—this to come into force at the expiration of a reasonable time, to allow of extra accommodation being provided when required. It is surprising that this matter has not yet been mentioned in connexion with the new Bill, seeing that it entails more misery and hardship upon the transported lunatic (and his friends) than almost any other provision of the existing lunacy laws.

I am, Sir, yours faithfully,
S. A. K. STRAHAN, M.D.

May 20th, 1885.

"PERSONAL EXPERIENCE OF COCAINE AS AN ANÆSTHETIC."

To the Editor of THE LANCET.

SIR,—In last week's issue you publish a letter from Mr. Wm. Copeland, M.R.C.S., of Staindrop, near Darlington, headed as above. In this letter Mr. Copeland states his belief that "he is the first member of the profession who has undergone a serious operation under the influence of the new anæsthetic." Whilst I sincerely congratulate Mr. Copeland upon the success of his case and Dr. Bell Taylor in having such an able advocate, I would point out that, in this neighbourhood at all events, Mr. Copeland is not the first member of the profession who has been operated upon for senile cataract under the influence of cocaine.

In February last I operated upon Dr. Welford, an eminent and much respected member of our profession in Sunderland. Dr. Welford, who perhaps at some future time may be induced to give his experience of the new drug, suffered no pain, and is now in the enjoyment of perfect eyesight.

I am, Sir, yours truly,
CHRISTOPHER S. JEAFFRESON.

Newcastle-on-Tyne, May 26th, 1885.

DEAR DR. JEAFFRESON,—I have just been told THE LANCET of last week publishes a case (Mr. Copeland, of Staindrop) as the *first* operation on a medical man in the north for removal of cataract under the influence of cocaine. Now, if this was done subsequent to Feb. 15th, 1885, it is *not* the first, for on that day you operated on my eye under cocaine, and successfully removed, without the slightest pain whatever, a cataract, "its success manifest in my writing this letter." With many thanks for your great kindness and skilful manipulation,

Believe me, dear Doctor, yours sincerely,
GEORGE WELFORD.

Cotherstone, Darlington, May 25th, 1885.

IRELAND.

(From our own Correspondent.)

HONOURS FOR THE MEDICAL PROFESSION.

THE rumours that several members of the profession in Dublin would receive distinctions from the Government appear to have been without foundation. The visit of the Prince of Wales to this country was a most successful one, and all classes vied with each other to make his stay agreeable. That they succeeded is conceded on all hands, and naturally it was expected by the profession here that the visit would have been marked by distinctions being conferred on some leading members of the medical profession. The honours, however, appear to have been doled out with no liberal hand. Dr. Wycherly, it is true, has been knighted; but this distinction was conferred solely on account of his holding the office of High Sheriff for the city of Cork. It may be argued that these matters rest with the Prime Minister, and not with the Prince of Wales. This may be correct; but, on the other hand, there can be no doubt that the slightest wish of His Royal Highness in these matters would at once have been attended to. At all events, the medical profession here must feel itself slighted at the indifferent manner in which it has been treated by the authorities.

HOUSING OF THE POOR COMMISSION.

On Saturday last the Royal Commission appointed to inquire into the housing of the working classes in Dublin commenced its duties under the presidency of Sir C. Dilke, M.P. The witnesses examined included the officers of the Local Government Board, the chairman of the Public Health Committee, Dr. Cameron, medical officer of health, and others. The proceedings, being private, cannot be published at present; but complaints have been made that the examination of four witnesses was conducted simultaneously, and that sufficient time was not devoted to the hearing of evidence by such an important Commission. It has also been alleged that although important evidence was tendered on the first day, it was declined on the ground of being "too late." Another sitting was held on Tuesday, but if carried out in the same manner, little good can be expected from its labours.

CORK SOUTH INFIRMARY.

The trustees of this infirmary have advertised for two surgeons and a physician, to be appointed on June 12th next, in accordance with a rule of the institution, which states that all officers of the staff appointed after 1876 shall cease to hold office at the end of five years, but shall be eligible for re-election. The objections to such an arrangement are many and manifest, and consequently the medical practitioners in Cork have recently held a meeting to take into consideration the question of these vacancies. The meeting appears to have been undivided in its opinions, as the resolutions were unanimously adopted. These resolutions stated that the medical profession in Cork considered the system of electing the staffs of the various hospitals for a limited period would tend to lower their status; and that no medical man should oppose the re-election of any member of a hospital unless he had been neglectful of his duties. These resolutions have been brought under the notice of the trustees of the infirmary.

ADELAIDE HOSPITAL.

The late Mrs. Bolton of Bective Abbey, County Meath, has bequeathed to this institution a perpetual rent charge of £400 a year, to be applied to the maintenance of some distinct ward or branch of the hospital, and to be called the "Bolton Donation."

A MORGUE FOR KINGSTOWN.

Kingstown, a seaport town some seven miles distant from Dublin, is greatly in want of a morgue for holding inquests, and as a receptacle for the bodies of persons found in the harbour. The coroner for the district has on several occasions drawn attention to the disgraceful neglect in providing such a building, but up to the present without success. The commissioners of the township are, I understand, the responsible authorities, and it is to be hoped they will take the necessary steps without delay to supply the defect.

The Earl of Rosse has been elected Chancellor of the University of Dublin.

On Monday last the Lord Mayor of Dublin formally opened the new baths and washhouses in Tara-street, which have been erected at a cost of £5000.

Dublin, May 26th.

PARIS.

(*From our Paris Correspondent.*)

THE LATE PROFESSOR BOUILLAUD.

THE statue that was erected in honour of Professor Bouillaud at Angoulême, his native town, was unveiled on Saturday, the 16th inst., in the presence of the notabilities of the place and of several members of the profession from Paris and elsewhere, most of whom were pupils of the illustrious physician. There were also present delegates from the various learned societies to which Dr. Bouillaud belonged—Professor Vulpian representing the Academy of Sciences, Dr. Henri Roger the Academy of Medicine, and Professor Laboulbène the Faculty of Medicine of Paris. In the most emphatic language the orators retraced the professional life of Dr. Bouillaud, commencing from his doctorate to the day of his death. He had scarcely left the school of medicine when he made an important discovery, showing the parts played by phlebitis, and the obliteration of the veins, in the production of certain forms of dropsy. He was not quite thirty years of age when he published his treatise on Encephalitis, in which he affirmed that the seat of articulate language is in the anterior lobes of the brain; at forty he published his Medical Nosography. His works on Essential Fevers, Medical Philosophy, and Acute Articular Rheumatism (in the latter of which he established the law of coincidence of inflammation of the sero-fibrous membranes of the heart, which opened a new field to pathology), and his treatise on Diseases of the Heart are sufficient to place Bouillaud among the members of the profession of the present century who have contributed by their works to create a new era in the practice of medicine. In 1826 he was promoted to agrégé of the Paris Faculty of Medicine; in 1825 he became member of the Academy of Medicine; in 1831 he was appointed hospital physician, and in the same year to the professorship of Clinical Medicine, which he occupied for nearly half a century with so much credit to himself and advantage to his pupils, who are now scattered over all parts of the civilised world. He was also a member of the Academy of Sciences.

THE ELIMINATION OF ARSENIC.

At the last meeting of the Paris Society of Medical Jurisprudence, Professor Brouardel reported a case illustrating the possibility of an infant at the breast being poisoned through its mother's milk. In his capacity of medical jurist he was consulted about a case which was lately brought before the tribunal, in which a man was accused of having attempted to poison his wife with arsenic, which he gave her in her food, she having at the same time a sucking baby. The infant was seized with symptoms of cholerine a few days after the mother had been affected in a similar way—diarrhœa, vomiting, &c., from which it died. These symptoms having occurred during the hot season, no importance was attached to them; but in the month of November following, the wife and mother-in-law of the accused having been again similarly affected, suspicions were aroused, and Professor Brouardel caused the body of the infant, which had been buried six months, to be exhumed. According to the Professor's report, the body was completely transformed into cadaverous fat, and it was impossible to isolate the viscera from the other parts, so that the body had to be analysed *en masse*. It weighed about two and a half kilogrammes, and contained five milligrammes of arsenic. Means had been taken to make sure that the arsenic did not come from the linen enveloping the corpse, nor from the earth which surrounded the coffin. The question then suggested itself as to whether the arsenic found in the body of the infant might not have been eliminated by the milk of the mother. To ascertain the possibility of such a circumstance, M. Gabriel Pouchet performed some experiments which were very conclusive. He administered to a certain number of wet-nurses, who were in the St. Louis Hospital affected with skin diseases, from two to twelve drops of Fowler's solution, and he ascertained that in these conditions the milk of the nurses always contained a relatively large quantity of arsenic; thus, the milk of one nurse, who had taken eight milligrammes of arsenic in six days, contained one milligramme of the metalloid to 100 grammes. M. Pouchet observed that these doses did not affect the nurses or their nurslings in the least. But upon the suppostion that the result might be otherwise if a large dose of the arsenic were administered at once, and in order to clear up this point, M. Pouchet tried experiments on some females among the lower animals. This series of experiments did not furnish conclusive results, as animals present a variable degree of susceptibility to arsenic, and it was therefore impossible to draw any comparative conclusions. It may, however, be deduced from these researches that the elimination of arsenic takes place principally through the milk, and it is therefore prudent never to administer arsenic to mothers suckling infants.

Paris, May 26th.

EGYPT.

(*From a Correspondent.*)

THE annual examinations at the Egyptian School of Medicine began on May 16th, and were attended on that day by his Highness the Khedive, all the Ministers, the Cadi, the Sheikh el Islam, and a few other visitors. The lecture theatre, which bears on its walls the names in Arabic of Hippocrates, Galen, Æsculapius, Asclepias, Dupuytren, Nélaton, Morgagni, and other classic names, together with those of some Oriental celebrities unknown to English ears, was luxuriously decorated in honour of the occasion. A fifth year's medical student was orally examined before the Khedive, then followed a fifth year's pharmaceutical student, who very rapidly discovered that three previously unknown solutions contained bichloride of mercury, acetate of lead, and nitrate of silver. Lastly, a Mussulman pupil midwife, closely veiled, was examined *vivâ voce* in her art, and was even made to apply the forceps to the dummy before the august assembly. The Khedive was then conducted over the new museums, which are a valuable nucleus for the future, and show a considerable improvement over their condition twelve months ago. One large room now contains valuable acoustic and other physical instruments, which were recently discovered packed away in an old storehouse, and are probably relics of gifts to the medical school in olden days by Dr. Clot Bey and Napoleon III. A medical tourist who recently visited Cairo has exposed the nakedness of the school of medicine in no sparing terms, but a glance at the accompanying figures will show that it is unfair to blame the professors for not providing efficient laboratories and museums. It will be seen that the whole income for the three combined schools of medicine, pharmacy, and midwifery reaches only £14,914, of which £2175 remain after paying for salaries and for the food and clothing of the students. Very little reform can be effected with this absurdly small sum.

School of Medicine and Pharmacy.		
Director	£900	
23 Professors and Assistants	5730	
35 Servants	866	
Food for Male Students	734	
Various Expenses	148	
		8378
School of Midwifery.		
4 Professors	282	
5 Servants	67	
Food for Female Students	167	
Various Expenses	8	
		524
Clothes for all Students	3993	
Teaching Materials	1837	
Furniture	90	
Small Expenses	92	
		6012
Total		£14,914

The income has been this year summarily reduced by £3000 in consequence of the general financial reform in Egypt, and it is greatly to the credit of the Director of the School that any of the recent improvements have taken place. He has succeeded in obtaining leave to spend £1000 this year on scientific instruments for laboratories, and it is to be hoped that the order which has already gone to Paris will contain elementary instruments of practical value, instead of being spent entirely in costly microscopes for demonstrating bacilli. Plans for building additional museums have also been drawn out, and £2000 of the necessary £10,000 has this year been placed at the disposal of the school authorities. It is satisfactory also to note that out of 150 students at present in the school 75 now pay £14 a year for the privilege of being educated. Formerly the Government bore the expense of all students, as their parents being mostly of the peasant class were unable and unwilling to contribute anything towards their education. Much unostentatious good work is being done at Kasiel Ain Hospital, which adjoins the Medical School. Mussulman women nurses are being trained for the first time, a system of house-surgeons and dressers has been started, and sawdust and corrosive sublimate dressings have taken the place of charpie and commercial carbolic acid. A new women's ward has been opened, and an operating theatre has been commenced, which will prove a great boon to both surgeons and students. During the last week the following interesting cases were admitted into the surgical wards:—

CASE 1. A Soudanese, who stabbed himself in the abdomen after an unsuccessful attempt to shoot an English soldier who passed him in the street. This man, when brought to the hospital, had three coils of large intestine, about two feet and a half in length, outside his abdomen. These were cleaned and returned, and he is recovering without a bad symptom. He probably consumes opium or hasheesh, and it is interesting to note that he required almost a gramme of opium in twenty-four hours to be put under the influence of the drug.

CASE 2. An Egyptian woman was brought in suffering from omental hernia without any covering, which had been exposed for a week, but had given rise to no abdominal symptoms. This patient was found walking about in the ward the day after the operation, and is rapidly recovering.

CASE 3. A fracture of the surgical neck and dislocation of the head of the humerus, not seen until three days after the injury. The dislocation was very easily reduced under chloroform.

At the beginning of this month a weak strumous child was operated on for swollen cervical glands at the earnest wish of its parents. On the seventh day after operation hæmorrhage occurred from a small branch of the external carotid, and this was readily controlled by the thumb of the native "probationer" nurse, who had only been under Dr. Milton's training for four months. The midwife when summoned also applied direct pressure to the wound, and was intelligent enough to refuse offers of perchloride of iron from a house-surgeon. When Dr. Milton arrived in the ward, he found the child pulseless and moribund. Injections of ether and other treatment proving useless, he at once bared his own elbow, drew off a sufficiency of blood, and injected it into the jugular of the patient, unfortunately not saving the child's life. Such a lesson as this is incalculably of more value to student doctors and nurses than any of the prolonged efforts of memory which most school teaching in Egypt requires, and it is by such individual acts of courageous self-sacrifice that the good name of Englishmen in Egypt is sustained, and a counterpoise may perhaps be effected to the unfortunate feebleness of administration of England in this country.

Cairo, May 20th.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the College was held on the 28th inst., Sir W. Jenner, Bart., President, in the chair. The gentlemen nominated at the last meeting, and whose names appeared in our impression of the 2nd instant, were duly admitted to the Fellowship. The late Dr. John Thorburn of Manchester was one of the gentlemen elected, and sympathetic reference was made to the fact of his death by Dr. Priestley, on whose motion the College resolved to address a letter of condolence to the widow.

A letter was read from the Secretary of the Royal College of Surgeons with respect to the appointment of seven delegates from each College to confer on the question of granting the title of "Doctor" to persons who shall have obtained the licence of the College of Physicians and the diploma of the College of Surgeons. A memorial was also presented by Dr. W. Hickman, urging the desirability of a complete conjunction between the Colleges. The President nominated Dr. Wilson Fox, Dr. Ord, Dr. Norman Moore, Dr. Moxon, and Sir Andrew Clark, Bart., with the President and Registrar, to act as delegates from the College.

On the motion of Dr. Norman Moore, it was resolved to guarantee the sum of 200 guineas towards the expenses of publication of the manuscript notes (1616) of Harvey's Anatomical Lectures.

The consideration of the Report of the Council upon the Croonian Trust was resumed. It recommended that "the residue of the income from the Trust, after payment of the Croonian Lecturer, be invested, to form a fund for the establishment of a Professor of Anatomy and Physiology, the person holding such professorship to be called the 'Croonian Professor of Anatomy and Physiology,' and to hold such professorship for five years." After some debate the Report was referred to a Special Committee, consisting of the Members of the Council and those Fellows who had given notice of amendments.

A Report was read from a Committee upon the Lunacy Bill, especially in reference to the question of the signing of certificates in lunacy, and a discussion ensued.

MEDICAL NOTES IN PARLIAMENT.

Medical Officers of Irish Prisons.

IN the House of Commons on the 21st inst. Mr. Hibbert, in reply to Mr. Macartney, stated that the medical officers of Her Majesty's prisons in Ireland who gave evidence before the late Royal Commission received the same allowances as those paid to medical officers appearing as witnesses before other commissions and select committees. These allowances were calculated to cover professional losses, and that included the payment of a substitute where necessary.

Medical Act Amendment Bill.

Mr. Mundella, in reply to Mr. A. O'Connor, stated that he was not aware of any intention on the part of the Government to reintroduce the Medical Act Amendment Bill of last session, and was understood to add that he did not think such a step was probable.

Protection against Cholera.

On the 22nd inst., in reply to Dr. Cameron, Mr. G. Russell stated that he was aware that Dr. Ferran was testing at Alcira the efficacy of vaccination as a remedy against cholera, and he had seen a telegram from him containing a statement as to the facts contained in the question, and asking that a commission should be sent out. The Local

Government Board was considering whether it could comply with the request; but the telegram was only placed in his hands on the 21st inst., and there had been no time to come to a decision in the matter. If the Department thought it desirable to send out a commissioner, he would undertake to bring the matter under the notice of the Secretary of State for India, as India was even more interested than England in the prevention of cholera.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen passed the first part of the Professional Examination for the Fellowship at a meeting of the Board of Examiners on the 25th inst.:—

Edmund Vaudrey, St. George's and Edinburgh; James T. James, Middlesex; J. Bowring Lawford, McGill and St. Thomas's; Henry J. Blakesley, Birmingham; A. F. Gambell Codd, St. George's; Robert Heelis, St. Thomas's; Harry Littlewood, University College; Charles S. Blair, Newcastle and London.

(Candidates referred, 12.)

Passed on the 26th inst:—

G. Adlington Syme, Melbourne and King's College; Alfred H. Tubby and A. Sneyd Taylor, Guy's; A. Ward Collins, University College and Liverpool; Robert T. Kent, Edinburgh and Guy's; John W. Smith, Edinburgh; Leonard A. Bidwell, St. Thomas's; A. Hancock Middleton, Dublin; Hugh Smith, London and Guy's.

(Candidates referred, 11.)

Passed on the 27th inst.:—

W. H. Breffit Brook and Wilfred Balgarnie, St. Bartholomew's; Henry P. Dean and Cyril W. Jecks, University College; Walter R. Jordan, Birmingham; Francis S. Hawkins and H. Evelyn Crook, Guy's; Arnold F. Bradbury, Newcastle; William H. Tomlinson, Manchester; William R. Ackland, Charing-cross; Ernest Solly, St. Thomas's.

(Candidates referred, 9.)

The library of the College is closed for the present for the purposes of the Fellowship Examination. The lectures will be resumed on Monday, June 1st, by Professor Edward Lund, F.R.C.S., the subject being "Some of the Injuries and Diseases of the Head and Neck, the Genito-Urinary Organs, and the Rectum."

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 21st inst.:—

Jones, Oliver Wentworth, Madras Medical College.
Roberts, Hugh Jones, Guy's Hospital.

The following gentleman passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise on the same date:—

Mallet, Thomas Charles, St. George's Hospital.

ON the 27th inst. Sir Charles Dilke addressed a crowded meeting of the Ladies' Sanitary Association at Dublin.

THE Queen has appointed John Foreman, Esq., medical officer of the Virgin Islands, to be a member of the Executive Council of those islands.

A MEETING, under the presidency of the Bishop of Bedford, was held on the 20th inst., for the purpose of aiding the East London Nursing Society.

IN the case of Page *v.* Harrison an order was recently made by the Divisional Court for a new trial, on the ground that the verdict for the plaintiff of £150 damages was against the weight of evidence. In the Court of Appeal on the 21st inst. the decision of the Divisional Court was affirmed.

CHARING-CROSS HOSPITAL.—The Queen has contributed a special donation of £50 towards the Triennial Festival Fund now being raised at Charing-cross Hospital for providing accident wards, a children's ward, and other improvements. The triennial festival dinner was held on the 20th inst. During the evening subscriptions amounting to about £6500 were announced.

SOCIETY FOR TRAINING TEACHERS OF THE DEAF.—The annual general meeting of this Society is to be held at the Training College, Elmhurst, Castlebar-hill, Ealing, to-day (Saturday). At 4 P.M. the annual exhibition of the pupils of the school will take place, when an opportunity will be afforded to visitors of witnessing the method of instruction and noting the progress of the pupils.

THE medical superintendent of the hospital ships *Atlas* and *Castalia* has issued a report regarding the work carried out on these ships in the treatment of small-pox patients in the metropolis.

AT the annual court of the governors and subscribers to the Victoria Hospital for Sick Children it was stated that the cost of the additional building decided upon would be about £4500, and of this amount only £3000 has as yet been collected.

PRESENTATION.—On the 15th inst. a marble time-piece with bronze side ornaments, and an illuminated address, subscribed for solely by the working classes of Darlington, were presented to Dr. Hern, late house-surgeon at the Darlington Hospital.

IT is stated on authority, says the *Australian Medical Journal*, that for the year ending December 31st, 1883, out of 11,173 births in South Australia, 9895 were successfully vaccinated, as shown by fees paid for returns. This is equal to 88·5 per cent. of registered births.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 21st inst. the following degrees were conferred:—Doctors of Medicine: William Collier, Jesus; Edward Ground, Downing. Bachelor of Medicine: William Foster, St. John's. Bachelor of Surgery: Alfred Francis Street, Trinity.—Mr. Henry Tempest Dufton has been elected to the Tancred Studentship in Physic at Gonville and Caius College.

NORTH-EASTERN HOSPITAL FOR CHILDREN.—From the report which was read at the seventeenth annual meeting of the supporters of this institution on the 18th inst., it appears that during last year the number of in-patients treated was 620, and the out-patients 14,249, as compared with 637 in-patients and 14,548 out-patients in 1883. The income of the hospital during the year from all sources, except legacies, amounted to £4225 being an increase of £65. The decrease of expenditure was about £70, taking into consideration outstanding accounts on Dec. 31st, 1884. Last year a debt was due to the bankers of £4000, which had been reduced this year by £200.

AT a meeting of the Holbeach Board of Guardians on the 8th inst., Dr. O'Meara, medical officer to the Sutton Bridge district, applied for an increase of salary. The applicant stated that his salary was £20 per annum, or a little more than 7*s.* a week. In his district there were forty paupers entitled to his services, and his patients of that class averaged ten per week and thirty bottles of medicine. The district was a scattered one, and he was compelled to drive hundreds of miles in the year to fulfil his duties. If a case occurred in one portion of the district needing daily attendance, he would be compelled to drive seventy miles a week, and expend 14*s.* a week in bridge tolls. The board declined to grant an increase.

UNIVERSITY COLLEGE.—The distribution of prizes to the successful students in the Faculty of Medicine at this institution took place on the 20th inst. The following are the principal awards:—Herbert Caiger obtained an entrance exhibition of £100, H. M. Fernando one of £60, and S. K. J. Brock one of £40. The Atchison scholarship was obtained by Raymond Johnson, as was also the Bruce medal. C. J. Arkle was awarded the Atkinson-Morley scholarship, and H. P. Dean the Cluff prize. In Practical Surgery, the Erichsen prize was obtained by E. H. Thane. In Physiology, G. E. Rennie, in the senior class, was awarded the gold medal, and C. H. Fernau and J. P. Parkinson silver medals, while in the junior class H. M. Fernando obtained a silver medal. G. E. Rennie obtained the gold medal in Anatomy, and C. H. Fernau and J. P. Parkinson silver medals, and in the junior division G. White was awarded a silver medal. In Medicine, F. W. Burton obtained the gold medal, and H. H. Brown and S. E. Holder silver ones. Raymond Johnson received the gold medal in Surgery, and E. H. Thane a silver one. In Practical Chemistry, H. W. Picton was awarded the gold medal; H. H. Cayley and H. B. Kitchin, silver medals. The Tuke medal in Pathological Anatomy, was awarded to Raymond Johnson. E. H. Thane received the gold and Raymond Johnson the silver Fellowes medals in Clinical Medicine; F. W. Gee obtaining a silver medal in the junior class. In Clinical Surgery, J. J. Lister obtained the Liston medal, and in Clinical Dental Surgery Raymond Johnson was awarded a prize.

North-Western Association of Medical Officers of Health.—At the monthly meeting of the members of this Association on the 14th inst. it was resolved, with regard to Mr. Phythian's paper on "Tenure of Office by Medical Officers of Health," that the hon. secretary should communicate with the Metropolitan Society of Medical Officers of Health and the Yorkshire and Midland Association, with a view to some united action being taken to remedy the unsatisfactory position of medical officers in this respect, and to suggest the formation of a joint committee to secure the desired alteration, and to ensure that such alteration should be embodied in any measure of local government reform introduced before Parliament. Mr. Vacher then read a paper on "*The Inspection of Meat Markets*," and a short discussion followed.

Bristol Medical School.—The annual exhibition of prizes to the students of this school took place on the 18th inst. The principal awards were as follows:—Summer Session: Practical Chemistry, Mr. Henry Hamilton. Practical Physiology and Histology, Mr. Frederick Lace. Botany, Mr. Theodore Mayo Stiles; *Lecturer's Prize*, Mr. Herbert John Thomas. Materia Medica and Therapeutics, Mr. John Henry Fardon; *Lecturer's Prize*, Mr. Henry Hamilton. Obstetric Medicine, Mr. Herbert Alfred Burleigh. Practical Surgery, Mr. Francis Frederick Jones. Medical Jurisprudence, Mr. Alfred John Tomkins. Winter Session: Anatomy and Physiology (junior classes), Mr. Samuel Wolferstan Morgan. Senior Class of Anatomy, Mr. Theodore Mayo Stiles. Senior Class of Physiology, Mr. Theodore Mayo Stiles. Practical Anatomy, Mr. F. Lace. Chemistry, Mr. Chas. Meaden. Medicine, Mr. W. C. Swayne. Surgery, Mr. Harless Frederick Semple and Mr. Walter Carless Swayne (equal).—Bristol Royal Infirmary: Suple Medical Prize, Mr. John Ernest Trask. Suple Surgical Prize, Mr. Charles Edward Stuart Flemming. Crosby Leonard Prize for Proficiency in Surgery, Mr. John Ernest Trask. Tibbits Memorial Prize, Mr. William Connor Lysaght. Clarke Prize, Mr. Henry Frederick Semple. Pathological Prizes, Mr. Charles Edward Stuart Flemming and Mr. John Ernest Trask (equal).—Bristol General Hospital: Martyn Memorial Entrance Scholarship, Mr. Wm. Henry Ware. Clarke Scholarship, Mr. Wilfred Martin Barclay. Sanders Scholarship, Mr. Arthur Nicholas Little and Mr. John Bartlett Webb (equal). Lady Haberfield Prize, Mr. John Bartlett Webb.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning at the latest.*

Beddoes, T. P., M.R.C.S., has been appointed Clinical Assistant in the Skin Department, St. Thomas's Hospital.

Burford, Geo. Henry, M.B., C.M.Aber., has been appointed Assistant Medical Officer to the Crumpsall Workhouse and Receiving Wards, New Bridge-street, Township of Manchester.

Edlin, Holburton, F.R.C.S.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Compton-Gifford Urban Sanitary District, Devonshire.

Elder, George, M.D., C.M.Glas., has been appointed Surgeon to the Samaritan Hospital for Women, Nottingham.

Evans, Robert, M.R.C.S., L.R.C.P.Ed., has been appointed Assistant Medical Superintendent to the Hackney Union Infirmary, vice Dr. Fuller, resigned.

Gordon, T. E., M.B.Dur., has been appointed Resident Surgeon to the Birmingham General Dispensary, vice H. Shillito, M.B.Lond., resigned.

Garry, C. D., M.B., L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

Griffith, A. Hill, M.D.Aberd., has been appointed Assistant-Surgeon to the Manchester Royal Eye Hospital.

Harries, Arthur, M.D., Senior Assistant-Physician to St. John's Hospital for Diseases of the Skin, has been appointed Consulting Physician to the Association for the Supply of Pure Vaccine Lymph.

Houghton, Lambert, L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Amersham Rural Sanitary District, vice Hosegood, whose appointment has expired.

Hull, Walter, M.B., L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

Johnson, G. D., L.R.C.P., M.R.C.S., has been appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

Kidd, H. Cameron, L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Ear Department, St. Thomas's Hospital.

[illegible], Robert W., B.A., M.B.Cantab., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Kendal District Union and Workhouse, and Public Vaccinator to the Kendal District.

[illegible], Alexander, M.B., C.M.Glas., has been appointed Medical Officer for the Llanelly District of the Crickhowell Union.

Lucas, Samuel Adams, L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer for the Second District of the Parish of Liverpool, vice Kennedy.

Lyon, T. Glover, M.A., M.D.Cantab., L.R.C.P., M.R.C.S., has been appointed Non-resident House-Physician to St. Thomas's Hospital.

Macdougall, Aymer R., M.B.Ed., M.R.C.S., has been appointed Surgeon to the Chesterfield and North Derbyshire Hospital.

Petherick, Wallace, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Hopton and Hepworth District of the Thetford Union, vice Gurdon.

Priestley, Joseph, B.A., M.B., M.R.C.S., has been appointed Resident Medical Officer to the Chelsea Hospital for Women, vice James Harper, M.D.Lond.

Plowman, S., L.R.C.P., M.R.C.S., L.S.A.Lond., has been appointed Clinical Assistant in the Throat Department, St. Thomas's Hospital.

Rees, Hugh, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Menai Bridge Urban Sanitary District.

Ritchie, E. D., B.C.Cantab., M.R.C.S., L.S.A.Lond., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

Roberts, Edward, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Manchester Royal Eye Hospital, vice A. Hill Griffith, M.D.Aberd., resigned.

Robinson, H. B., L.R.C.P., M.R.C.S., has been reappointed Resident House-Physician to St. Thomas's Hospital.

Rouse, Rolla E., M.B., M.R.C.S., L.S.A.Lond., has been appointed Resident Accoucheur to St. Thomas's Hospital.

Sanctoshi, Y., L.R.C.P., M.R.C.S., has been appointed Non-resident House-Physician to St. Thomas's Hospital.

Staddon, J. R., L.R.C.P., M.R.C.S., has been appointed Assistant House-Physician to St. Thomas's Hospital.

Stevens, Arthur Frederick, M.R.C.S., has been appointed Medical Officer for the Sapistone District of the Thetford Union.

Vachell, R., M.D., has been appointed Out-patient Medical Officer to the Glamorganshire and Monmouthshire Infirmary and Dispensary, vice T. Wallace, M.D., resigned.

Van Buren, Ernest C. Haward, L.R.C.P.Ed., M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse of St. Mary Abbotts, Kensington, vice Atkinson.

Wallace, T., M.D., has been appointed Surgeon to the Glamorganshire and Monmouthshire Infirmary and Dispensary.

Williams, R. M., L.R.C.P., M.R.C.S., L.S.A.Lond., has been appointed Resident House-Physician to St. Thomas's Hospital.

Wilson, Arthur Cobden Jordan, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Penistone District of the Penistone Union, vice Watson.

Births, Marriages, and Deaths.

BIRTHS.

Austin.—On the 25th inst., at West Norwood Lodge, Knight's-hill, Lower Norwood, the wife of J. A. Austin, M.D., prematurely, of a son (stillborn).

Collenette.—On the 6th inst., at Silverdale, Staffs., the wife of F. de Beauchamp Collenette, L.R.C.P.Lond., &c., of a daughter.

Lucy.—On the 20th inst., at The Elms, Enfield, the wife of William C. Lucy, M.D., C.M., of a son.

Pratt.—On the 15th inst., at Gibraltar, the wife of Surgeon W. Simsen Pratt, Army Medical Staff, of a daughter.

Pritchard.—On the 25th inst., at Heath-rise, Hampstead, the wife of Urban Pritchard, M.D., F.R.C.S., of a son.

Wade.—On the 21st inst., at the County Asylum, Wells, Somerset, the wife of A. Law Wade, M.D., Superintendent, of a son.

Ward.—On the 24th ult., at Neemuch, Central India, the wife of Surgeon-Major E. C. R. Ward, F.R.C.S.I., Medical Staff, of a daughter.

MARRIAGES.

Edwards—Kemp.—On the 9th inst., at Tientsin, China, E. Henry Edwards, M.B., C.M., to S. Florence, third daughter of the late G. T. Kemp, of Beechwood, Rochdale.

Jones—Cole.—On the 30th ult., at St. Mary's Church, Brighton, Hermann Johnston Jones, M.D., M.R.C.S.Eng., L.R.C.P.Lond., to Hannah Cole, of Notting-hill, W.

Morgenrood—Reid.—On the 25th ult., at Capetown, Edward Henry Morgenrood, M.D., son of the late Philip Morgenrood, of Wynberg, Cape Colony, to Marian Beatrice (Minnie), youngest daughter of Wm. Wardlaw Reid, of Corra Linn, South Norwood, Surrey.

DEATHS.

Baker.—On the 19th inst., at his residence, Barham House, Leamington, Robert Large Baker, M.D., F.R.C.S., formerly of Birmingham, aged 65.

Budd.—On the 21st inst., at Southernhay, Exeter, Samuel Budd, M.D., J.P., in his 79th year.

Greensill.—On the 14th inst., at "The Firs," Martley, Worcester, Joseph Moore Greensill, M.R.C.S., &c., aged 28.

Lesly.—On the 29th inst., at Abu-Fatmeh, on the Lower Nile, of enteric fever, Robert Lesly, M.D., Army Medical Department, the youngest son of the late William Sole, M.D., F.R.C.S., and of Anne, his wife, now of St. Mary's, Southampton, aged 29.

Nicholls.—On the 27th inst., at Devizes, J. F. Nicholls, M.D., aged 65.

Thorburn.—On the 27th inst., at his residence, Moss House, Rusholme, John Thorburn, M.D., Professor of Obstetric Medicine in the Owens College, Victoria University, Manchester, aged 51 years. Friends will please accept this the only intimation.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, June 1.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10.30 A.M., and each day at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1.30 P.M., and each day at the same hour.

St. Mark's Hospital.—Operations, 2 P.M., and on Tuesdays at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M., and on Thursday at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

Royal College of Surgeons of England.—4 P.M. Prof. Edward Lund: On some of the Injuries and Diseases of the Head and Neck, Genito-Urinary Organs, and Rectum.

Royal Institution.—5 P.M. General Monthly Meeting.

Odontological Society of Great Britain.—8 P.M. Casual communications by Messrs. W. St. George Elliott, C. W. Dunn, A. Maggs, S. J. Hutchinson, and F. Canton.—Mr. C. S. Tomes: On Experiments on Amalgam Fillings.—Dr. G. Field: Pivot Teeth attached by Cohesive Gold.

Tuesday, June 2.

Guy's Hospital.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

Cancer Hospital, Brompton.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 2.30 P.M.

Central London Ophthalmic Hospital.—Operations, 2 P.M., and on Friday at the same hour.

Royal Institution.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

Wednesday, June 3.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

St. Mary's Hospital.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

St. Thomas's Hospital.—Operations, 1.30 P.M., and on Saturday at the same hour.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Central Hospital.—Operations, 2 P.M.

Samaritan Free Hospital for Women and Children.—Operations, 2.30 P.M.

University College Hospital.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

Royal Free Hospital.—Operations, 2 P.M.

King's College Hospital.—Operations, 3 to 4 P.M.

Royal College of Surgeons of England.—4 P.M. Prof. Edward Lund: On some of the Injuries and Diseases of the Head and Neck, Genito-Urinary Organs, and Rectum.

Obstetrical Society of London.—8 P.M. Specimens will be shown. Dr. John Williams: *Serous Perimetritis.*—*Dr. Matthews Duncan*: The Hypertrophies of Lupus of the Female Pudendum.—Mr. W. S. A. Griffith: Notes on a Specimen of the Pseudo-Osteo-Malacic Pelvis of Naegele.

Thursday, June 4.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Surgical Consultations, 1.30 P.M.

Charing-cross Hospital.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2.30 P.M.

Royal Institution.—3 P.M. Prof. C. Meymott Tidy: Poisons.

Ophthalmological Society of the United Kingdom.—8 P.M. Living Specimens.—8.30. P.M. Adjourned Discussion on the President's paper on Reflex Ophthalmitis.—Mr. Spencer Watson: Intra-ocular Gumma in a Child the subject of Inherited Syphilis.—Mr. J. B. Lawford: Tubercle of Choroid —Dr. W. A. Brailey: Double Retinal Glioma resulting in the Shrinking of one Eye and the Perforation of the other by a large Growth from within.—Communication by Mr. G. A. Critchett: Case of Extreme Retinal Irritability with Abnormal Visual Phenomena.

Friday, June 5.

St. George's Hospital.—Ophthalmic Operations, 1.30 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

King's College Hospital.—Operations, 2 P.M.

Royal College of Surgeons of England.—4 P.M. Prof. Edward Lund: On some of the Injuries and Diseases of the Head and Neck, Genito-Urinary Organs, and Rectum.

West London Medico-Chirurgical Society.—8 P.M. Dr. J. Syer Bristowe: Hysteria and its Counterfeit Presentments (Cavendish Lecture).

Royal Institution.—9 P.M. Prof. Dewar: Liquid Air.

Saturday, June 6.

King's College Hospital.—Operations, 1 P.M.

Royal Free Hospital.—Operations, 2 P.M.

Middlesex Hospital.—Operations, 2 P.M.

Royal Institution.—3 P.M. Rev. C. Taylor: "*The Teaching of the Twelve Apostles,*" an Ancient Document, with Illustrations from the Talmud.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Medical Men in New South Wales.

From *information published by the* Immigration Office, Sydney, New South Wales, it appears that in the cities and larger townships of the Colony there is no lack of competent medical men, but in the newer and more remote districts they are too often conspicuous by their absence, and it is by no means unusual for the inhabitants of such places to advertise their willingness to guarantee a certain amount of income to a resident doctor. An experienced medical man, willing to "rough it" for a few years, will attain a competency much more rapidly than in England, especially if devoted to his profession and skilled in the treatment of complicated cases. Medical specialists possess a wide field in Australia, where institutions for the treatment of eye and ear diseases, &c., are practically unknown.

Mr. E. E. Wadbrook is referred to a general notice at the head of this column.

COCAINE TABLETS.

To the Editor of The Lancet.

Sir,—I can fully confirm Dr. Dolan's experience of the value and efficacy of the cocaine tablets. I have recently made some observations with them, which I trust may be of interest. I dissolved one of the one-sixth-grain tablets in three minims of water, and introduced it into my left eye. There was no pain or irritation; but in from two to three minutes there was well-marked anæsthesia, so that I could touch the conjunctiva with the point of a sharp penknife without experiencing inconvenience. In five minutes dilatation of the pupil was noticed, and at the expiration of ten minutes it was complete, there being at the same time paralysis of accommodation. The anæsthesia lasted for thirty-five minutes, and the dilatation for four hours. With the one-tenth-grain tablets the symptoms were of the same nature, but less pronounced. I find, with Dr. Dolan, that it is not necessary to dissolve the tablets in water, but that they may be introduced directly into the eye without inconvenience. I have used them frequently in the casualty department with most gratifying results. They are admirably adapted for the removal of foreign-bodies from the eye, the pain and photophobia being at once allayed. In one case especially, where the patient's eye was full of unburnt gunpowder, the result of an explosion, the relief was very marked. Injected hypodermically, a ligature having been previously applied to a limb, these tablets induce an amount of local anæsthesia sufficient for the performance of small operations, such as the opening of an abscess. I have never seen any untoward effect from the use of the drug, and have myself taken as much as three grains at a dose hypodermically without inconvenience. In the treatment of neuralgia of the eyeball cocaine is, in my experience, by far the best remedy.—I am, Sir, your obedient servant,

Eber Caudwell,
Assistant House-Surgeon to the Westminster Hospital.

May 26th, 1885.

The Case of Strangulated Hernia at Stockport.

In an annotation in our issue of the 9th inst. we directed attention to a case of umbilical hernia reported in the daily papers. The observations there made were suggested by the evidence which reached us, and we took occasion to state that we might not have been fully informed of the facts. From information since received, it appears that Mr. Buist succeeded twice in reducing the rupture within a few days of the suddenly fatal issue. Herniotomy for strangulated umbilical rupture is an exceedingly unpromising procedure; and yet we think it preferable to leaving the patient to the chances of spontaneous reduction when taxis has failed. Such cases are indeed difficult to deal with, and for that reason we freely admit that at most Mr. Buist committed an error of judgment in not consulting some senior member of the staff of the Stockport Infirmary, of which institution he is a valued officer. It is matter of regret that a post-mortem examination was not made, and the pathological facts placed beyond surmise.

L.R.C.P.—Our advertising columns often contain announcements of the kind indicated. Otherwise we know of no such institutions save those enumerated in the Medical Directory.

Mr. Arthur T. H. Trevor is thanked for his correction of a quotation.

Dr. Cobbold.—Too late.

"NO DOCTORS AMONG THE PEERS."

To the Editor of The Lancet.

Sir,—I was greatly struck by an annotation under this heading which appeared in The Lancet of the 16th inst. It seems to me that unless the leaders of the profession of medicine and surgery make a decided stand for their dignity misconceptions will continue to exist with regard to the true status of the profession. When medicine and surgery were practised by illiterate men, who were barbers as well as bleeders, there was perhaps an excuse for the absence of State recognition. But now there is an impassable barrier to prevent such persons being identified with the "healing art." Our noble profession can only be entered as the result of a thorough course of practical training and of passing a series of searching examinations at universities or colleges. Hence it is that at the present day its members include men of the highest intellectual culture and social position; men who have made their mark in the world of science by their discoveries and research for the alleviation of human suffering and the preservation of human life. I allude to such men as Jenner, Paget, Gull, Lister, Spencer Wells, Clark, Bowman, Playfair, Thompson, and many others. With such illustrious names I fail to see why science should not be represented among the peers as a tribute to science, just as literature is represented, and indeed all the learned professions. Moreover, I fail to see why the profession of medicine should not hold at least as high a place in the public estimation, and therefore in that of the State, as any other profession; as, for instance, the Army, the Navy, the Bar—ay, even the Church itself. But as regards State recognition, the medical profession, in comparison with the others, comes last of all. Again, in the House of Commons, while there are upwards of 120 barristers and 100 military men, there are only four medical men. The public can easily judge what a gain it would be to the community to have the benefit of the experience of medical men in legislating for the prevention of disease and the promotion of the health and comfort of the working-classes. How many important medical subjects are continually being discussed in that legislative council from time to time?—in many instances decided by those whose knowledge must be immeasurably inferior to that of men who have devoted their lives to the subjects in question. Among the many subjects about to be brought before Parliament, and which emphatically demand the best attention of a sound medical opinion, are the following:—The Medical Acts Amendment Bill; the health and management of prisoners; the treatment of habitual drunkards; overcrowding, and the proper housing of the working-classes in cities; the further restriction as to the pollution of rivers; the opposition to compulsory vaccination; and last, not least, the vivisection question.

For the foregoing reasons I repeat that our scientific profession—shall I not say the most scientific and enlightened of the present day—should be properly and fairly represented in both Houses of Parliament, as are the sister professions, to assist in deciding great and momentous questions. It seems to me that nothing but the blindest prejudice—a prejudice unworthy of enlightened statesmen—can have so long stayed the hand of the Sovereign, and prevented the elevation of the representative men of our order to seats in the Upper House, which Lord Salisbury once told the country "was chiefly valuable because it represented success in all lines of public usefulness, from commerce to statesmanship." The late Lord Beaconsfield, too, stated, in a speech delivered on Nov. 9th, 1875, that "a policy that diminishes the death rate of a great nation is a feat as considerable as any of the decisive battles of the world." The present Prime Minister, Mr. Gladstone, has frequently spoken in strong terms of his admiration of the increasing importance of medicine and the medical and surgical professions. "That profession," he said, "presented a future of the highest interest. There was in that future the probability that it would gain increased influence, greater as compared with other professions."

The remarkable incident recently reported, of a peer requiring medical assistance in the House of Lords, when Lord Spencer, with great presence of mind, secured the services of a professional commoner from the Lower House, is certainly not my reason why life medical peerages should be created in the same way as legal life peerages have been; but I take the far higher ground—the rights of the medical profession to equal rank and position with any other. If the rights of the profession are not acknowledged, then we ought to endeavour to induce more of its members who can afford it to enter the House of Commons, and, by well-directed combination, show the State that the profession has a political influence if it chooses to exercise it.—I am, Sir, yours truly,

Lambert Hepenstal Ormsby,
M.D.Univ. Dub., F.R.C.S.
Dublin, May 23rd, 1885.

To the Editor of The Lancet.

Sir,—With reference to the annotation in your issue of the 16th inst., under the above heading, I beg to express my full accord with your sentiments. Nor do I suppose that many of our body would dissent. Although the powers that be may think that to give a doctor a baronetcy is an honour to the profession sufficient to its needs, still I venture to submit that we honour the powers by accepting it. And so far from feeling hurt at the Premier's remark that you quote, I think we may well afford to treat it as an ignorant and childish insult. For though in whatever country we may practise we are subject to the laws of that country, still our interests do not cease there. We are all the world over members of the same united body, which has for its aim the consummation of science and art in their relation to humanity, the imitation of the highest attribute of the Deity. And as such we can happily remain unhonoured by those who are unable to conceive our high and noble aims, and *sine honore* we need none of us hesitate in feeling our superiority over any of our patients be they kings or paupers. Earthly honour we seek not, we seek but a clear conscience and a true understanding of the Supreme Being.—I am, Sir, yours obediently,

"Magnum et Gloriosum est pro Professione Vivere."
May 2[illegible]th, 1885.

The University of Naples.

The number of students entered at the University of Naples for the current scholastic year is 3527. Of these, 1472 are law students, and 1353 students of medicine, the remainder being distributed through the scientific and classical schools.

J. W. (Stoke-on-Trent).—We do not prescribe. Avoid advertising quacks.

An Old Subscriber.—We regret we have not the information at hand.

Mr. Bellamy.—Yes.

COCAINE IN HAY FEVER.

To the Editor of The Lancet.

Sir,—In your issue of May 16th one of your correspondents asks whether the application of a weak solution of cocaine to the conjunctivæ and the mucous membrane of the nose would be likely to prove beneficial to sufferers from hay fever. Within the last three weeks I have had two cases which would seem to indicate that the remedy in question might fairly be tried, and with a reasonable prospect of success. The first case was that of a lady who for three weeks had suffered from neuralgia, in which the supra-orbital and infra-orbital nerves were affected. Under treatment she made a good recovery, save that on the right side of the nose, at the junction of the bone and cartilage, there was left a constant aching so severe in character as to prevent rest or sleep. I ordered the affected part to be painted with a 2 per cent. solution of cocaine every twenty minutes; after the fifth application the pain entirely ceased. The cocaine was also applied to the mucous lining of the nostril on the affected side. Five days ago another lady consulted me for a painful affection of the nose on the right side, the pain radiating underneath the eye. It came suddenly, and disappeared suddenly, three or four times in the course of twenty-four hours, and was invariably preceded by severe fits of sneezing. This lady assured me that she sometimes sneezed as many as twenty times consecutively. I ordered the nose and cheek to be painted with a 2 per cent. solution of cocaine, and the mucous membrane of the affected side to be brushed over with the same. After four applications, the sneezing became less violent, and for two days she was free from the annoyance. I think the cocaine solution has been beneficial, and in such cases should be tested. In cases of hay fever it is worthy of a trial; but I should, in the first instance at least, confine its application to the lining membrane of the nose.

I am, Sir, yours respectfully,
A. G. Russell.
Strathmore, Harrogate, May 21st, 1885.

THE VOLUNTEER MEDICAL SERVICE.

To the Editor of The Lancet.

Sir,—"A Volunteer Surgeon" asks, in your issue of the 16th inst., to be recommended the books containing the details necessary to be acquired in order to obtain the pass certificate for Volunteer surgeons. As the requirements have increased considerably during the last few years, I would advise your correspondent to apply direct to the principal medical officer of his district, who will give every assistance in his inquiries. The present requirements necessitate a knowledge of all the details of the bearer company, general hygiene of a camp, medical aid in the field, and the regulations connected with military hospitals as detailed in the Medical Regulations, which unfortunately are out of print. A new edition of the "Stretcher-bearer Drill" now general in the Volunteer force is about to be issued. A knowledge of this drill in all its details would also be required. Many of the minor matters connected with marches, diet, filtration of water, &c., are discussed in Parkes' Hygiene, which work, with the hospital portion of Longmore on Gunshot Wounds, is recommended to be obtained.—Yours truly,

A Volunteer Surgeon-Major.
May 2[illegible]th, 1885.

DOCTORS *v.* PHYSICIANS.

To the Editor of THE LANCET.

SIR,—In your issue of the 25th ult. appeared two letters on the above topic. As they are written in much the same strain, they may conveniently be considered together. An attempt is made to create, or to encourage, an unfriendly spirit, by advising the use of mean expedients by the holders of one qualification to depreciate and annoy the possessors of another. Let the M.D. of somewhere consider himself vastly superior to his neighbouring L.R.C.P.Lond. if he likes; but he certainly has no right to employ every available opportunity for using either the snub direct or oblique, as recommended by one of your correspondents. With your permission, I will recount a tale and point a moral.

A few years ago I entered one of the largest London hospitals, having previously had two years' training at a public dispensary in the metropolis. I thought that in due course I should be able to get a doctor's degree. I found, however, the London University closed to me, unless I gave up a deal of valuable time to reading for the Preliminary Scientific examination. Deeming that my object in entering the hospital was to render myself a trustworthy practitioner of medicine rather than the temporary possessor of biological minutiæ, I resolved to give up the quest, and to go in for the L.R.C.P.Lond. and M.R.C.S., the only good qualifications open to me without interrupting my studies by leaving London. Some of my fellow-students, with an amount of worldly wisdom, seeing not only that the London degree was impossible for them, but that the London Colleges were beyond their reach, went to Scotland, where they and their fees were welcomed; and in due time these men returned with their M.B., C.M., only to wait a short time, when they would without any effort ripen into the higher degree. Now, only one of these graduates held any clinical appointment at the hospital, and, with that one exception, they would be classed among the *non-industrious men of their year. In the meantime, many of us* remained in London, steadily working through the clinical appointments and getting our qualifications.

I will now ask, Why are we, who are every whit as well educated and professionally qualified as the majority of M.D.'s, and better than some, to be spoken of as *little* better than impostors because we elected not only to commence but to pursue our professional education in London rather than elsewhere? It may be remarked in passing that even the M.R.C.P. is closed to us, as the holder of it is precluded from general practice. I trust the time is not far distant when we physicians will be taken out of our present false position and given a title of some real value. It is certain that if something is not done in this direction our London schools will wane with increasing rapidity.

I am, Sir, your obedient servant,

May 20th, 1885. PHYSICIAN AND SURGEON.

SYPHILITIC INDURATION OF A CICATRIX RESEMBLING MORPHŒA.

To the Editor of THE LANCET.

SIR,—The *following case is of some interest as indicating* a possible close connexion between morphœa—especially those cases which disappear comparatively rapidly—and syphilis.

A. B——, aged forty, had the left arm injured by cogwheels, the skin and cellular tissue on the outer side near the elbow being divided by several parallel cuts. About a month after the wounds had completely and soundly healed the cicatrix became indurated, and instead of being thin and soft, appeared half an inch or more in thickness, and closely resembled morphœa. I found that the patient had had a hard chancre a short time previously, the remains of which were still evident. Under antisyphilitic treatment the induration of the cicatrix on the arm began to disappear, and after some weeks the cicatrix resumed its normal appearance.

In the absence of evidence of recently acquired syphilis, I should have been compelled to diagnose the foregoing case as one of ordinary morphœa following an injury and developing in the cicatrix.

I am, Sir, yours obediently,

Nottingham, May 25th, 1885. H. HANDFORD, M.D.

MAHOMED MEMORIAL FUND.

DR. AUSTIN FLINT of New York has forwarded to us the sum of £1 in aid of the above fund.

Dr. Ferris of Uxbridge is thanked for his letter and enclosure. Our remarks, as he perceived, were written on the ground that the period of incubation in his case was unusually long even for hydrophobia.

W. M. has not enclosed his card.

Dr. J. A. Gray (Atlanta).—We cannot extend our exchange list.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Chaplin, Jerusalem; Dr. E. Crookshank, Dresden; Dr. Russell Reynolds, London; Dr. Cobbold, London; Dr. Ewart, London; Mr. Barwell, London; Dr. Collingridge, London; Mr. Jackman, Coggeshall; Dr. Handford, Nottingham; Dr. Prosser James, London; Dr. Oliver, Harrogate; Mr. De Méric, London; Mr. Twyford, Hanley; Mr. Field, London; Mr. Turner, St. Petersburg; Dr. Thin, London; Mr. C. J. Stocker, Forest Gate; Mr. Chavasse, Birmingham; Mr. St. John Wright, London; Mdlle. V. de Bunsen; Mr. W. Steer; Dr. Savage, London; Mr. B. Pollard, London; Dr. Brailey, London; Mr. Percy Dunn, *London*; *Mr. P. J. Thompson, Brussels*; *Mr. Somers* Vine, London; Mr. W. P. Fox, Liverpool; Mr. B. Squire, London; Dr. J. Tily, Chiswick; Dr. Colquhoun, Dunedin; Dr. H. E. Armstrong, Newcastle-on-Tyne; Mr. P. W. Macdonald, Dorset; Mr. A. C. Munro, South Shields; Dr. Ormsby, Dublin; Mr. C. S. Jeaffreson, Newcastle-on-Tyne; Dr. J. D. Thomas, London; Dr. Irwin; Mr. Brocklehurst, Matlock; Mr. Furland; Mr. Fairman, Bruntsfield; Mr. Prodham, London; Dr. Diver, Keighley; Mr. Green, Derby; Mr. Lonergan, Hythe; Lieut.-Gen. The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed *to* initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not *only* affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Address

TO THE

STUDENTS OF THE MEDICAL SCHOOL AND UNIVERSITY COLLEGE, BRISTOL.

Delivered after the Distribution of Prizes, on May 18th, 1885,

BY J. RUSSELL REYNOLDS, M.D., F.R.S.

PROFESSORS OF THE FACULTY OF MEDICINE, LADIES, AND GENTLEMEN,—First of all, let me express, for you and for myself, our heartiest congratulations—and that means "rejoicing with those who do rejoice"—to those who have been successful to-day. This not only because of the prizes that they have gained—although these are good things in themselves, and to be highly prized both now and hereafter,—but because they are marks of good "training" and tests of "strength." There are three things that success in college competitions, or I might say more generally that college competitions put to the test, which it is well to have tried, and that in good time, for they will furnish much guidance for after-life. They may be put thus: (1) *strength* both of body and mind, and upon that depends much of what people regard as "temper"; (2) the *method* of study; and (3) the *capacity* for reproducing, when wanted, the knowledge and the skill that you have acquired. There are two classes of men, especially marked from one another, who compete for prizes; and, as an old examiner in university and in college, you will let me tell you that they are generally quite easily distinguished from each other, and this in both their "written papers" and in their *vivâ-voce* answers to the questions that may be submitted to them. There are great and numerous varieties in the style of answer, but no practised examiner can fail to recognise the difference between the two classes of men that I have mentioned. In the one, the man has been working for the pass or the honour that he wanted to obtain; in the other, the man has been working to gain the knowledge which makes that pass or that honour well deserved. Men of either class may obtain their reward; but the reward of the one is of far higher value to himself and to others than is that of the second, which may sound the same; but yet be something that neither he, nor others, will care for, when a few months have passed. Before I say a few words of congratulation to the unsuccessful, or rather, *to those* who have run, but "have not obtained the prize," let me, as a much-tried examinee, as well as examiner, take this occasion to remind you, both prize-takers and prize-losers, that the element of chance is not without its influence in either pass or honours' examination. It is as easy to exaggerate as it is to underrate this factor; but it should always be borne in mind. Let no failure be referred to it alone; let no success lead you to ignore it.

How it may be in this school of medicine I do not know, but in many schools, both metropolitan and provincial, those who enter upon "competitive" examination are in a small minority; and of this I am *quite sure*, that the majority, composed of those who never try their strength until they face a court of examiners for a simple pass, deprive themselves of one great and highly important element in their education. If all students practised themselves in the art of expressing themselves well in both written and oral examination, a very much smaller number would, when they come before the examining boards, be "referred again to their studies." No man, until he has tried it, knows usefully how to write the answer to a question without note or reference-book at hand, or to answer swiftly and to the point, *vivâ voce*, a question suddenly put to him, and the character of which he did not in the least expect. To those of you who have not been so successful to-day as you could wish to have been, let me say this, that most likely you have gained for yourselves something better than a "prize." You have learned why you have failed, and such knowledge is of vast importance. You—for men at the same school are very sharp critics and judges of one another—know why others have succeeded and why you have not.

Think back for a moment upon the three elements in successful competition—those I mentioned a few moments since: (*a*) *strength* and tone of feeling with regard to study. Some are what may be called "languid." They do not use all the power they have, sometimes only a small fraction of it, which they may deem quite sufficient for the occasion. This may be from either flaccidity of moral fibre or from overweening self-confidence. On the other hand, there are some who are over-anxious, and their work is done under a dominating feeling of the fear of failure; and their feeling is often the unwilling father to the fact. This often leads to (*b*) an error in the *method* of study, and the greatest of all errors is this: to make the passing of an examination the object of your work, and to substitute it for the "mastery of the matter" you want and ought to obtain. Work done in this frame of mind is invariably and in the main bad work. If it should end in some success, it may lead to "vanity;" if it fails, it carries with it only "vexation of spirit." Again, in referring to (*c*) the *capacity* for reproducing, when wanted, the knowledge that you have already acquired, let me remind you of the presence of two great factors in that which constitutes what is habitually termed "a good memory." There is (1) the *storage* of information and (2) the faculty of *finding* what you have stored. Individuals differ widely in the degree to which they are naturally endowed with these faculties, but each may be increased by education. The first depends mainly upon your power of "attention," the second upon the "orderly" manner in which you arrange the materials in your possession. If you try to add *to your stores when* your power of "attention" is weakened, you will send one thing out of your head while you are putting another in, and your brain, like an overcharged popgun, will sometimes lose both shots. By no amount of clever manipulation can you put *anything more into any created* thing than its capacity can hold. If you pack your carpet-bag to the full, and then jam in something else, the probability is that you cannot lock the bag: you have hurt it or torn it somewhere, and have lost something that you much wished to keep, and probably much more valuable than the last trifle of your "cram."

Then think, *again, of* what *it is to* pack carefully—i.e., with attention, arranging with foreknowledge of your requirements what you will want first, second, and last, and contrast this with the unordered heaping of things together in a limited space, the impossibility of catching what you want, and the certainty of finally finding that you have, metaphysically, to turn yourself "inside out," and, like a startled parrot, to pour out in unmeaning succession all you know and all that you can say. So, then, if you would have a "good memory," pay attention and be orderly. Practically cultivate these two capacities, and so by concentrating your attention on a sound (it may be stethoscopic), on a something to see (it may be microscopic); but do this with both ears and both eyes open: follow through a symphony in the full rush of sound, a single strain or a single instrument, while hearing all the rest; see all that you can see in a landscape, but single out something that you must look for to see at all, and so raise to its highest degree your attentive power.

And so with "recollection." Put all things in order, and then close your eyes and ears, and recall all that you have stored, where it is, what it is, why you placed it in this or that other place, and how you may most easily find it—and that will be very often in the dark.

Speaking to all, I would say, generally, that if we have regard to the three points laid down, pay due regard to the element of "chance," and then add that "unknown quantity," the x, y, z, of College life, successful and unsuccessful will find that unknown quantity to be very small, and will be able to explain to one another—as they should always be most glad to do why the race has not more frequently ended in a "dead heat." A single success or failure, be it ever so great, may be the result of the merest chance, but progressive success or failure, year after year, takes them altogether out of the chapter of accidents, and should be the careful study of all. Regard prizes as milestones not as goals. They may tell you how far you have travelled, how far many are before you, and how far many are behind, and then explain to yourself by careful thought and inquiry why you are where you are. The prize tells you how much you have already attained; but if it does not tell you also how much more you have to do, it has taught you little.

Before I leave this subject, let me say to you in Bristol what I have often said to my pupils in London, that, so far as my knowledge extends, there is nothing laid down by our great examining bodies which any ordinary student, without either genius or fag, could not pass through with perfect ease if, and it is an important "if," he will only go on steadily and systematically at his work. The strain for "honours" has often broken men down, and they have to rest and lose their time, and not rarely miss the "pass" that they might have readily obtained. Most thoroughly do I admit the differences in degree of capacity for "honour"-taking among "all sorts and conditions of men." No one can doubt the existence of a "genius" any more than he can that of an utter "fool"; but I think that if *in medio tutissimus ibis*, you will find the majority by your side. So let me add a word to some who work too hard—i.e., try to do more than they need to do, and, moreover, trouble themselves about it a thousand times more than they ought to do; and I allude to many scores who have broken down in the very faculties they most sorely needed, and to whom I have had to say, "you must go away and rest," remembering, then, as Shakespeare says,—

> "As surfeit is the father to much fast,
> So every scope in the immoderate use
> Tends to restraint."

And now let me tell you that when you have finished here, and have satisfied college, university, and hall, your real examination begins, and it is one that will last for life. Your examiners will be your patients, and your patients' friends, and you will find them not more lenient than those you have already passed. But the same qualities which have helped you now, and until now, will be your helps hereafter in the daily toil of practice. First, you must hold in due regard your strength and temper. "Never," as Edmund Parkes said, "think of your life, but always of your health, which alone can make life useful." You will find much to try, disappoint, and vex you; but you must be firm and of good courage, and you must show your patience when men, like drowning men clutching at straws in their hour of agony, will when safely on the bank, through your energy and skill, give you nothing but a cold shoulder, or grumble at your fee. There is, always remember, another side to this. To many you will be friends for life. There will be homes which will become homes to you, and no event, from the cradle to the grave, will be left unchronicled in their hearts and yours. This, second, will depend mainly upon yourselves and how your way of work has helped or depressed them. You cannot solve the problems of the sick-room in one quarter of your cases by stethoscope, thermometer, or any such like means. It is by knowledge and sympathy that the help is given. Like good actors, you must so throw yourselves into the mental and moral condition of those with whom you have to deal that you think their thoughts and feel their feelings, and so understand their wants and try to fill them. Again, third, your knowledge and your skill must be always ready, not lying in dust-covered books upon your shelves, but always at your fingers' ends.

Success will mainly depend upon yourselves. If it is true that the poet is born, not made, that dogma is quite as true with regard to the physician. You must be men that your patients and their friends can trust, and do so without knowing it. You must be calm, without indifference; judgmatic, without dogmatism; clear and ready, without rashness; kind, but with both tenderness and firmness. You must always avoid that tenour of mind which I take leave to call "a chronic chorea of ideas." You must go at once and straightly to what you want to say and do, and not let your fancies, your hobbies, and scarcely remembered knowledge come in your way and misdirect the movement that you mean to make, or else you will find that "enterprises of great pith and moment" will often "turn awry, and lose the name of action." And here let me caution you against reading much or contributing anything to the ephemeral literature of the day. Hasty generalisation is as easy as it is bad; and many things are being constantly brought forward in societies and pamphlets as great and surprising novelties which you may find well described in such classic works as Watson's Lectures, the monographs of Williams, of Louis, of Walshe, of Frerichs, of Abercrombie, Rayer, and Andral.

Before you enter your profession you should "count the cost." There is no great prize in it. Nothing that approximates the "prizes" to be gained in either the Church, the Bar the Army, or the Navy. There are no great "honours" that you can gain. You may receive the kind and degree of reward that is given to the conveyer of a "despatch," or to a worthy country mayor who has long voted consistently with his party; but you may not look with hopeful eyes for anything beyond. You may die on the battlefield, or be heavily shotted as you sink into the ocean in the darkness; you may be maimed or killed by a lunatic; or be fever-struck in a workhouse, an asylum, or a gaol, where you are doing work that the country has given you to do. There may, perchance, be two or three lines about you in a local paper, the medical press of London may give a short history of your life. You may leave behind you broken hearts in more than your own one sad home; but that is all. There is no adequate recognition of the services of our noble Profession granted by either State or country; but there is one thing to which, when your work here is done, every one of you may attain, and this without rivalry of any sort or to any degree. You may, in the solemn silence of your own heart, in that court of appeal into which none but God Himself can enter, after giving thanks for all the goodness you have received from Him, say your "Nunc Dimittis"; and although you may not hear the sob or the unspoken word, yet you will be followed by the unuttered prayer that all bereaved and sorrowing souls know so well, "Requiescat in pace." But I will not close in this somewhat sombre strain, although it has its bright as well as its darker tones. One of our greatest poets has said,—

> "The clouds that gather round the setting sun
> Do take a sober colouring, from an eye
> That hath kept watch o'er man's mortality."

But yet, although "the night be dark and dreary," and there may be many "starless nights and cheerless dawns," we must remember that the same great poet said, in another place, when glowing with the enthusiasm of growing life,

> "But for the growing youth
> What soul was his, when, from the naked top
> Of some bold headland, he beheld the sun
> Rise up, and bathe the world in light? He looked"—

And so let us, from our point gained to day. Look at what may be in store for some of you, or for some who follow you. What that may be I cannot tell; but yet we may, and we should, indulge the hope that, in that universal "light"—it may be far, far away in the future,—some one will live to see the future Edward Jenner, who may have saved, as his great predecessor had done, millions of lives from misery and death, placed somewhere in a niche of honour in our own country instead of in Boulogne, and not be relegated here, in England, from Trafalgar-square to an obscure corner at the far end of the Serpentine, where nursemaids are engaged in keeping erratic children from falling into its stagnant water.

Again, that the William Jenner of that far-off day, who may again have so disintegrated the sources of some of our most miserable maladies, and demonstrated, as his illustrious forefather had done, that by deeds of heroic scientific work, such as those now progressing, they are, in the main, "preventable diseases." Further, that the future Edmund Alexander Parkes, who shall have again lightened every soldier's knapsack, arranged his diet, ventilated field tent and hospital ward, and so saved thousands of the lives of England's bravest sons and soldiers; and, yet further, that the John Simon of "the coming race;" if there be, again, in one man combined such science, patience, thought, and self-sacrifice—one who shall, again, have protected our shores from enemies more deadly than any that our battalions or our ironclads can oppose;—then, I say, let us hope that it may be seen that, although these great men of the future may care as little as really great men have ever done for the honours that other and smaller men prize so highly, yet that our country may be the better for having placed them where they ought to be, with all the honour and glory that is their due, and which will, let us hope, be gladly awarded then by the heart, the larger heart, of this great and the greater nation.

> "Let us, then, be up and doing,
> With a heart for any fate,
> Still achieving, still pursuing,
> Learn to labour and to wait."

And not only so, but to work and wait in hope.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on May 27th, the degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on Robert Lawford Knaggs, Gonville and Caius.

Clinical Remarks

ON A

SE ILLUSTRATING LIABILITY TO ERROR IN DIAGNOSIS,

H FREQUENT PAINFUL ATTACKS, PROBABLY OF Y COLIC (REPUTED AS GASTRIC), OCCURRED DURING THAN TWO YEARS IN CONNEXION WITH MITRAL DISEASE AND DILATED HEART, THE FATAL ISSUE DETERMINED BY A SMALL CALCULUS LODGED IN ODENAL ORIFICE OF THE COMMON DUCT. JAUNDICE BLY ABSENT THROUGHOUT.

BY W. T. GAIRDNER, M.D., LL.D.,
FESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW.

MEN,—I have to-day (May 26th, 1885) to bring our notice a case interesting in more than one but particularly as illustrating an oversight or (if not error) in diagnosis. Errors in diagnosis, if not the result of mere carelessness (in which case , they have no redeeming quality except as a lesson individual), ought always to convey some kind of on to good clinical students, and therefore ought to insisted on, if possible, than instances of very exact ucky guesses at truth. In this particular case the omission affects one part of the diagnosis only, and ly fraught with instruction, and with what is, to ast, new and therefore valuable experience. This e I shall now endeavour to convey to you fresh sources, and you shall judge for yourselves of its ce and practical significance. The case, I may was repeatedly the subject of clinical remarks st winter session, and perhaps some of those here ay have these in their note-books.

end of December last[1] we admitted into the Infirmary a woman, Mrs. G——, aged forty-six, labouring under dilated and weak heart, with gurgitation, and just possibly also (but not cer- itral stenosis. There is nothing more to be said as rt of the case. The murmurs were so far charac- the one certain, the other all along doubtful. The ding conditions were found after death; the mitral ckened and fringed with lymph, certainly admitting itation, possibly—but by no means certainly—in a to give rise also at times to the direct murmur. s there is nothing new, and I shall not occupy your with it just now, though the details at the time resting enough, and the diagnosis here was exact at degree. Nor is there anything particularly novel ost of the sequelæ of the cardiac disease in this ere was dropsy, varying in degree at different ere was well-marked cyanosis, and a good deal of ; there was enlarged and congested liver; a con- dney also, yielding a urine mostly albuminous, and variable as to quantity and specific gravity; the mostly feeble, sometimes irregular and frequent, ery disproportionate in volume and force to the impulse of the dilated heart. With all these na in cardiac cases you must be quite familiar, and ve them not now under observation I merely thus e them. But what struck me in this case as even from the first, was the degree of what the hought, and we also thought, to be gastric suffer- report all through bears this upon the face of it: y first note of the case by myself, the day after , it is said: "The earliest symptoms, extend- to two years ago, seem to have been referred omach both by herself and her medical atten- want of appetite, occasional vomiting, and pain gastrium extending through to the back." Nine this she was first told that her heart was affected. one ought to say that painful disorders of the an very uncommon in heart disease, but the and severity of these apparently gastric sufferings in this case struck me as taking it quite out of the common range in this respect, and I believe I told you so at the time. This peculiarity, too, interfered with the administration of remedies; tincture of digitalis, at first prescribed, had to be stopped on account of sickness, though it acted with great energy upon the kidneys, and we were afterwards able to give Nativelle's granules of digitaline at least without injurious, and probably with good, results. A similar uncertainty seemed to attend the action of the convallaria majalis; it was in this case, therefore, beyond most others of last session, that I had occasion to thank Professor Fraser of Edinburgh for enabling me to employ a sample of the new cardiac tonic, strophanthus, which, after she became accustomed to the bitter taste of it, seemed to do everything that was expected from it, and not to excite the gastric irritation. But the numerous detailed reports show the great amount of difficulty we experienced in treating this case, owing to symptoms which, even when the cardiac and renal conditions were manifestly improving, were "referred more to the stomach than the heart" (February 7th—i.e., six weeks after admission). A week later we have again an allusion to the "ill-defined and gastric character of the symptoms" (then in abeyance). "She speaks of a sense of 'chuggin' (I make no attempt to render this word into scientific language—it must speak for itself) in the epigastrium, which she evidently attributes to the stomach and not to the heart." From this time improvement was, on the whole, progressive; but on February 27th there is a note, even in the midst of this improvement, that "for the past two days she has been troubled with intestinal colic" (here the word "intestinal," I must observe, is not mine, but embodies the theory of the resident physician); "but this symptom has been relieved by the use of assafœtida pills." She was dismissed on March 20th, 1885, after a residence of nearly three months, in a very greatly improved condition as regards the heart, and with the following highly satisfactory note as to the action of strophanthus, which I here place on record, in justice to a new, and probably a valuable, medicine. "Nothing like sickness has been experienced in the course of the treatment by strophanthus; patient only remarking that the medicine was very bitter."

Now, observe carefully all the preceding expressions taken from the hospital report; and further, note with me the sequel of this case, and then judge whether the whole or the greater part of the symptoms assumed to be gastric (or in one case "intestinal") are not rather to be referred to the biliary passages, as the result of the transit of a probably numerous succession of small gall-stones; since the post-mortem examination shows the terminal and severe epigastric sufferings to have been unquestionably so determined. But in order to enable you more fully to apprehend this, and to appreciate the difficulties of the diagnosis during life, I must add one more, *though it be a negative, fact*; which, however, you will please consider as not resting on direct evidence, and therefore just possibly open to correction—viz., that at no time while this case was under observation, possibly at no time at all during its progress, was there any notable jaundice. Had there been jaundice, and had it been brought into obvious relation with any of those numerous so-called gastric attacks, it would hardly have been possible to miss the true diagnosis; the pain, at least, must have been regarded as probably hepatic, not gastric, in origin, and the variable and colicky character of it at times, the sense of "chuggin," the severe suffering extending from front to back, would probably have brought up the idea of gall-stone, and caused concretions to be looked for in the evacuations. Nothing of this kind took place. But it is not only because we did not observe jaundice that I assume its probable absence. Jaundice from gall-stone, or from any kind of obstruction of the passages, is always accompanied by a very greatly deepened and altered colour of the urine, which it is hardly possible to suppose, with even moderate care, to have been wholly overlooked. Now, we have nearly forty detailed clinical examinations of the urine in this case recorded carefully in a separate book, as having been made between November and March; in every one of these nitric acid was employed, not, indeed, expressly to detect bile, but as a test for albumen; and in not one of these notes (in which, I may mention, the colour of the urine was particularly recorded in a column by itself) is there the slightest hint or suggestion of anything like bile pigment. "Amber" was the prevailing tint, lighter or darker according to circumstances. I affirm, then, with a probability almost amounting to certainty, that there was no jaundice; with absolute certainty, no persistent or considerable jaundice during the whole of this period. Moreover, the patient never mentioned jaundice as a feature of the early attacks, while she herself believed the whole disease to be altogether in the stomach; and jaundice (as you well know) is a symptom which, almost more than any other, arrests the eye and enchains the mind of a non-medical observer, so that it is popularly spoken of as if it were the disease whenever it is recognised as present at all; and I can positively affirm that in her last hours and in the dead body the conjunctivæ and *the skin were not jaundiced.* It would be too much, perhaps, to maintain on this negative evidence that this woman was never at any time jaundiced; but there is good reason to presume that during a large part of her illness, and during the most marked prevalence of the symptoms above recorded, bile pigment was very little, if at all, abnormally present in the blood. Hence the error or omission in the diagnosis to which I have referred.

---

[1] Dec. 27th, 1884, Journal X., p. [illegible]

Mrs. G—— was admitted to the hospital again on May 18th, 1885, certainly much worse than when she was dismissed in March; but, according to my judgment, not worse than she had been at various periods during her former residence. Three days after her admission (May 21st) I made a most careful examination, keeping in view all the facts previously recorded, and found them *in statu quo*, with the qualifications just made; the cardiac action the same, the murmur the same; "the gastric symptoms formerly described still present, but by no means in an exaggerated form. Legs considerably swollen, and with a tendency to eczematous exudation on the surface, but not very tense. The temperatures absolutely normal. The urine, noted as 19 oz. on the day after admission, rose to 101 oz. on the 20th, and to 148 oz. on the 21st." Similar rapid variations in quantity[2] had been recorded during her former residence as occurring under remedies; this time the increase took place partly under digitalis, partly under convallaria with caffeine. She had been treated locally, on account of the abdominal or gastric suffering and supposed flatulence, with poultices and fomentations to the abdomen; also with turpentine and soap enemata and compound assafœtida pill. The pulse and respiration were both considerably accelerated on the 20th, the maxima being 45 and 128; but, as above indicated, there was absolutely no fever. In the course of the next afternoon (21st) "she complained of a good deal of pain regarded as mainly gastric, but the temperature showed no rise, being 98·8° in the morning and 98·6° in the evening. At 2 A.M. of the succeeding day (the 22nd) a rigor occurred, after which the temperature was noted as 102·4°, for the first time since admission within febrile limits. Dr. Rutherford, the resident physician, was sent for, and found that the rigor had passed away, but the pulse was small and uncountable. At 6.30 A.M. the temperature was 103·6°; the pain was very severe in the upper abdomen, and continued until followed by unconsciousness. At 8 A.M. she was completely unconscious, and at 9 A.M. she died.

If you ask me now what I expected to find at the post-mortem examination as the cause of the fatal crisis in this case, I must frankly confess at once that I cannot tell. I thought it indeed just possible that there might have been some perforation of a viscus—stomach or duodenum,—giving rise to peritonitis, or to inflammation perhaps limited more or less by adhesions. Looking to the long-continued history of gastric suffering, this appeared not an unreasonable expectation, and one of the few causes that would help to explain a death within seven hours from the first rigor and rise of temperature. Beyond this I felt unable to carry speculation as to the precise cause of death, and certainly, in the absence of jaundice, it did not occur to me to attribute the death or the fatal sufferings to gall-stone. Yet here we have a gall-stone caught, as it were, *in flagrante delicto*, actually imprisoned in the common duct at the time of death, and forty-four more of them remaining in the gall-bladder after death. But the very largest of these gall-stones appears, especially in the dilated state of the ducts, to be very inadequate to their complete closure. There is not one of them that measures even half an inch in its extreme diameter; and this one, closely resembling the impacted one in size, weighs only five grains. The smallest weighs only half a grain. All of them are facetted—that is, they have smooth, flat surfaces, separated by straight angular ridges. They must therefore have been at one time packed together pretty closely in the gall-bladder, yet not so closely but that some amount of friction took place, and the opposing surfaces were thus polished and rubbed quite smooth. But although the gall-bladder at death contained all these calculi, it was not even nearly full of them; it was, indeed, considerably dilated, and could easily have held many times the number found without stretching. Is it too much, then, to presume that there were, or may have been at one time or another, scores, or even hundreds,[3] of such gall-stones present, of which a great many were discharged *per vias naturales* into the duodenum, at the cost of much suffering, but without absolute danger to life?

But how did the one actually found in the common duct, being not larger probably than many of the others, and not visibly impacted so as to be inconsistent with its passing the orifice by means of a moderately sustained pressure, determine a fatal crisis? That I cannot tell, even now; all that can be said is that there was no other fact discovered at the post-mortem examination at all adequate to the production of these effects. The mucous membrane of the stomach and that of the duodenum were normal. The pancreas and the left supra-renal capsule presented "extreme hyperæmia." The liver was enlarged and congested (as we, in fact, knew that it must be a long time before death). The kidneys were enlarged and markedly hyperæmic. The heart was in the condition already referred to, and the aortic valve as well as *the mitral were slightly incompetent. That is all. It* would be more absolutely correct, perhaps, to say that this woman died *with* a gall-stone *in transitu*, than to say that she died simply *of* an impacted gall-stone. But the sufferings connected with the fatal event were unquestionably, *I think*, chiefly determined by the imprisoned, and as yet undelivered calculus, lying in the very outlet of the common duct. An hour or two more of suffering, a little more strength to bear it, less of congestive complications in the adjoining viscera, and she might have weathered this storm also, like the others before it. But the special instruction which the case conveys is to be found in the evidence it affords that so small a gall-stone, not completely closing the duct to the passage of bile, may nevertheless cause severe, and in this particular instance fatal, suffering; and further, that in all probability an unknown multitude of such calculi may pass in succession, all attended with similar sufferings (except as regards the presence of fever in the fatal crisis) without any jaundice being discoverable from first to last.

There are numerous cases recorded in medical literature, and preparations preserved in museums, illustrating the arrest of gall-stones *in transitu* from the gall-bladder to the duodenum, sometimes in the cystic, sometimes in the common duct. When the stone is a large one, and is therefore long retained in the cystic duct, there is of course during this period no jaundice. Dr. Murchison[4] records a case (cxvii. p. 368) in which "*the patient suffered from severe biliary colic daily for four months before jaundice appeared*, the stone, from its great size, being all this time detained in the cystic duct; and Trousseau[5] mentions a case *in which biliary colic occurred repeatedly during four years, and then for the first time jaundice occurred." In this case* Trousseau assumes that the calculus remained in the gall-bladder, occasionally getting into the cystic duct, with the result of producing the attacks of pain, and returning again to its original position. "In the fifth year," he adds, "the attacks became more severe, jaundice appeared, and the disease ceased upon the expulsion of a single calculus, shaped like an olive, the greatest diameter of which was two centimetres." In Murchison's very interesting case above mentioned there were grave doubts entertained as to the diagnosis, although thirteen years previously regular attacks of biliary colic, followed by jaundice, appear to have existed. Cancerous disease is apt to be suspected in such cases, and was so in this case by some. But the post-mortem examination showed that a large gall-stone, probably long impacted in the cystic duct, had made its way latterly into the common duct, and was there retained, and had been ulcerating through the mucous membrane of the duodenum, so as to cause hæmorrhage and other unusual symptoms, among which was, for a time, "almost constant diarrhœa."

---

[2] Trousseau, in his admirably instructive and interesting lecture on Hepatic Colic and Biliary Calculus (Sydenham Society's Translation, vol. iv., pp. 227, 234), writes as follows on the quantity and physical characters of the urine:—"The icteric tint seldom appears till the day after the attack. . . . . Even during the attack, the urine, which is very copious, is limpid like water from the rock, being, in fact, what is called *nervous* urine. . . : . It is not till twelve, eighteen, or twenty-four hours later that it assumes [illegible] colour characteristic of jaundice; and [illegible] is not till then that it will appear." [illegible] ndice, &c.," 1870, entirely ignores this curious statement, which is also passed over by other considerable authorities. Dr. Legg is "inclined to put the first appearance of jaundice much earlier after obstruction; perhaps within the first twenty-four or forty-eight hours." Dr. Murchison recognises the *urina nervosa* not only as sometimes preceding, but as, under rare and exceptional circumstances, accompanying jaundice during brief periods. But in the case here recorded the excessive quantities of urine passed at times, and maintained for many days together, apparently under the influence of remedies, were never recognised as having any relation to the particular attacks of pain.

[3] Several cases have been recorded reaching one thousand or more. One such case is to be seen in the Hunterian *Museum in Glasgow* University.

[4] Clinical Lectures on Diseases of the Liver, &c., 2nd edition, 1877.

[5] Clinical Medicine (Sydenham Society's edition, 1871), vol. iv., p. 277.

But these cases, illustrating the long-continued absence of jaundice when the calculus is so large as to be detained in the cystic duct, can hardly be considered as throwing any light on the total absence of jaundice in our case, where the stones were so numerous and so small, and the biliary passages so much dilated throughout as to give them comparatively an easy and rapid course to the duodenum.[6] Assuming that the attacks of epigastric pain suffered at intervals for more than two years by our patient are to be regarded as similar in origin to the fatal attack, we can only suppose that the comparatively small size and facetted character of the individual gall-stones passed during this period incapacitated them from completely obstructing the duct, or that their very rapid passage gave no time for jaundice to take place in each separate attack. "If the stone finds its way into the bowels within twenty-four hours," says Murchison, following in the main Trousseau, "or if it does not get beyond the cystic duct, or if its form is so angular as not entirely to block the flow of bile, it is quite possible to have biliary colic without jaundice. ...... There is good authority for the statement that small biliary calculi have been found in the stools of individuals who have never had jaundice, but such cases are certainly exceptional; and I am unable to understand the statement of Wolff,[7] that twenty-five out of forty-five patients observed by him passed through the whole train of symptoms of biliary colic without jaundice, the concretions being found in the evacuations."[8]

In Von Schüppel's elaborate article[9] the following closely corresponding passage is found: "If the stone makes its way into the intestine after having been arrested in the common duct less than from twelve to twenty hours, or if it does not advance beyond the cystic duct, or if it is of angular form and the bile can flow alongside of it, no jaundice will occur, although hepatic colic is present. By bearing this in mind we shall understand those cases in which people suffer repeatedly from attacks of colic, which are regarded as gastric colic, because no jaundice ever appears, and in which the subsequent course of the disease leaves no doubt that the paroxysms of pain were really due to the presence of gall-stones. In such cases the diagnosis is sometimes confirmed by observing that the attack of pain is associated with a very slight yellow colouring of the conjunctivæ at least, or that the urine shows small quantities of biliary colouring matter."

These citations will serve to show that the case now brought before you is not, perhaps, altogether unexampled, although I confess that I had never before either seen or heard of one in which such a succession of attacks, extending over so long a time, and involving in all probability the passage of quite a multitude of gall-stones, had occurred without either yellowness of the skin and conjunctivæ, or the detection of bile pigment in excess in the urine. I have therefore thought it my duty as a clinical teacher to publish the case.

ADDISON'S DISEASE WITHOUT TUBERCULAR DEGENERATION OF THE SUPRARENAL CAPSULES.

BY J. WICKHAM LEGG, F.R.C.P. LOND.

IT would seem that the theory which makes tubercular disease of the suprarenal capsules an invariable accompaniment of the clinical symptoms of Addison's disease will have sooner or later to be abandoned. Eleven years ago there came under my notice the first of a series of cases in which undoubted Addison's disease has existed during life, and yet after death no tubercular disease of the suprarenal capsules has been found. A woman, thirty-seven years of age, about eighteen months before her death noticed a black line on her lips, and two months before this she had begun to be very weak, with shortness of breath; she was also subject to vomiting, which the patient herself called being bilious. On admission the face was noticed to be pigmented, while the sclerotics were a clear white; the buccal mucous membrane was also pigmented, the lips and the gums being marked with bluish-black lines, and the palate spotted with bluish spots. Further, on the arms were the little black pigmented spots which are considered so characteristic of Addison's disease. The legs, arms, and trunk were generally of a brownish colour, which was not more marked around the umbilicus or the mammæ. She died about a month after her admission into St. Bartholomew's Hospital, with symptoms of extreme weakness and vomiting.

The examination showed well-marked pigmentation of the knees, the inside of the thighs, the outer genitals, the abdomen, and the lips. Under the skin there was a fair amount of fat. There was no phthisis, and the only noteworthy appearances found in the body were connected with the suprarenal bodies. A very careful dissection failed to detect any right suprarenal body. First of all, the inferior cava was drawn down and the sympathetic nerves behind it dissected; no naked-eye appearances of disease could be made out; the place of the right suprarenal body was taken by a small lump of fat, not so big as a hazel nut, into which an artery from the junction of the right renal with the aorta could be traced. This little artery was about as thick as a common pin. On the left side there was found a black body in the place of the suprarenal capsule, and of its shape, but not of its thickness. It had vessels like those of the right capsule, but it was a mere shell; when cut into, one wall could at once be raised from the other, and there appeared to be nothing between them. This body under the microscope showed well-marked connective tissue fibres with numerous fat drops in the meshes, but no remains of the ordinary texture of the suprarenal body.

This case was noticed by Dr. Greenhow in the second Croonian lecture read before the College of Physicians in 1875, but he did not admit that it was a case of Addison's disease. And on these grounds—First, that there was a "bilious tendency to explain the vomiting." Now, it is true that the patient did say that she was often bilious; but those who have had much to do with hospital, or indeed other patients, will know that with them an onset of vomiting is usually called being "bilious." Though I thought it right to record the patient's own words, yet one is not bound thereby to an approval of what is said or of the theories of disease which are connoted in such expressions. Secondly, "the patient had lost four stone in weight during her illness." Now, these are again merely the patient's own words, and they possess only the usual worth of such statements. After death there was found a fair amount of fat under the skin. Last of all, it was objected that the temperature was above the normal. It was once 100°. I hardly think much stress can be laid upon a single observation, only 0·4 or 0·6 of a degree above what is natural. Besides, it will hardly be allowed that the temperature in Addison's disease is never raised. I have myself had under my care a very marked case of Addison's disease in a little girl of twelve, in whom the suprarenal capsules proved after death typical specimens of tubercular degeneration, and yet during her stay in the hospital the temperature was seldom down to 98·4°. This elevation of temperature seems to be now an admitted clinical fact, for I find in the last edition of Dr. Bristowe's "Theory and Practice of Medicine"[1] that the temperature sometimes "rises one, two, or three degrees." So that a temperature of 99° can hardly be considered a point sufficient altogether to exclude the diagnosis of Addison's disease; and this rise of temperature seems to be as little worthy of consideration as the thirst, swollen gums, and red, fissured tongue also pointed out as inimical to the diagnosis. On the other hand, the symptoms declared in the Croonian lectures to be so important were very marked—to wit, the shortness of breath, the weakness, the vomiting, and pigmentation of the skin and mucous membrane. With this last there was an appearance, "one of the most decisive external signs of Addison's disease," the small black patches of pigment on the skin of the arms.

---

[6] In this fact, too, is probably to be found the reason why the pain, though often no doubt considerable, never assumed under observation the exquisitely agonising character attributed to that of gall-stone; nor had it, I think, the extremely sudden invasion usually observed in the case of a large calculus, or even of a smaller calculus passing for the first time through the bile-duct.

[7] Virchow's Archiv, vol. xx., 1861: Beiträge zur Symptomatologie und Diagnostik der Gallensteine; von W. Carl Wolff, Pract. Arzte in Bonn. After a careful perusal of this interesting and valuable paper, I am disposed to attach more importance to its conclusions in this respect than Dr. Murchison appears to have done. But, as Dr. Wolff gives no details of his cases, it can only be here stated in general terms that they were mostly uncomplicated—i.e., without organic disease or serious illness of any kind, apart from the symptoms specially described. As only such cases are included as were actually found to have passed gall-stones with the evacuations, it is plain that a more or less considerable number of doubtful cases must have been eliminated. On the other hand, this fact gives to the study of the symptoms of the cases referred to an unusual measure of importance. Among these symptoms, next to pain and jaundice, the author has been led to give the first place to a slowing of the pulse, which takes place usually to the extent of from five to ten beats, and sometimes more, in the minute during the urgency of each paroxysm. This he observed in one case in which the attacks recurred almost daily, and were watched for many months, with all precautions against fallacy. In uncomplicated cases, whether with or [illegible] he found this symptom so constant that in doubtful [illegible] the leading element in the diagnosis.

[8] [illegible]

[9] [illegible]

While recording this case in 1874, in the St. Bartholomew's Hospital Reports for that year, I ventured to remark that if the facts were good, as there seemed no reason for doubting, some of the then prevailing theories as to the nature of Addison's disease would have to be greatly modified, or even altogether abandoned. And the progress of events has been somewhat in favour of what was then foretold. On the 7th February, 1882, two cases of atrophy of the suprarenal capsules with Addison's disease were laid before the Pathological Society by Dr. Goodhart (for Mr. George Eastes) and by Dr. Henry Davy; and more lately, on February 3rd last, several other cases were brought forward by such excellent observers as Dr. Coupland and Dr. Thomas Barlow, and Dr. Coupland gives an account of all the cases of atrophy of the suprarenal capsules and of Addison's disease, which have yet been published.

There is thus a considerable and increasing number of cases of Addison's disease in which all the symptoms of this malady have been present during life, but in which after death the tubercular degeneration of the capsules has been absent, and only a wasted and atrophied state of these organs has been discovered. These cases are quite different from those which were formerly brought forward as Addison's disease without tubercular degeneration—cases which were so imperfectly described or so imperfectly examined that the account of many of them need only be looked at to convince the reader of its worthlessness to prove anything. Cases in which only the kidneys have been examined, or cases in which disease of the suprarenal capsule has been found without any symptoms of Addison's disease during life, or cases in which no description is given of the disease found in the suprarenal body, may all be put aside at once. It may be that the ease with which such cases have been hitherto answered has led some of the defenders of the tubercular nature of Addison's disease to fancy that the more modern instances may be as lightly passed over. But these later cases are far more difficult to overthrow. They have been seen for the most part in the practice of experienced hospital physicians familiar with Addison's disease, and the examinations after death have been made by experienced morbid anatomists who were not likely to pass by any important and gross changes in other organs which could cause death. These can hardly be set aside by any amount of special pleading; such carefully worked-out cases would be almost enough in themselves to destroy any theory of disease to which they are opposed.

It may interest some to hear of another case in which the same set of appearances was noticed. My colleague, Dr. Church, drew my attention to the patient soon after her admission as a well-marked case of Addison's disease; yet, after death, hardly any suprarenal capsule on the right side, and only a wasted remnant of the organ on the left, could be discovered by Dr. Norman Moore.

A woman, aged twenty-nine, was quite well up to December, 1883, when she began to be short of breath, to be giddy, and to vomit. A month later the discolouration of skin began. On admission into St. Bartholomew's Hospital, in May, 1884, her skin generally was pigmented of a tawny-brown colour; two deeper patches of pigment were seen over the right eye and the xiphoid cartilage; the axillæ were deeply pigmented, but there was no excess of pigment over the breasts. The lips were slightly pigmented. The whole body was rather wasted, weight 6 st. 1 lb. There were no physical signs in the lungs, but there was a short harsh systolic murmur at the apex of the heart, which was not audible at the base. The glands under the jaw were considerably enlarged, especially on the left side. The urine contained no albumen or sugar. She continued to grow much weaker, and had many attacks of vomiting. On May 27th, coinciding with an attack of fever, it was noted that the colour had become much darker. She died on June 11th. This patient had paroxysms of fever. From May 16th to 18th the temperature was above natural, reaching on the evening of the 16th to 101·8°. It was also above natural from May 24th to May 31st, the highest point being 102·6°; and again four days before death, the highest point being 102·8°.

The examination was made by Dr. Norman Moore, about thirty-three hours after death. The body was found wasted, and there was much dark-brown pigment in the skin. This appearance was more marked on the abdomen than on the chest, and was very distinct around the nipples. The whole of the back was much pigmented. Nothing unnatural was discovered in the spinal cord, brain, or ears. The lungs were quite natural; the heart was small, the muscular tissue brownish, the valves natural; weight, 6¾ oz. The contents of the abdomen were natural, with the following exceptions: there were three large gall-stones with facets in the gall-bladder, but the ducts were quite free, and the right suprarenal capsule was represented by a small shred of tissue, quadrangular in shape, about half an inch long by a quarter broad. The left was black, of natural outline, but completely wasted, and as thin as paper. The solar plexus to the naked eye was quite natural.

If, then, as seems likely, we shall be forced to give up the theory of the necessity of tubercular degeneration of the suprarenal capsules to Addison's disease, have we any other theory to put in its place? I think at the present moment we must answer "No;" and in the very great obscurity in which the subject lies it will be rather an advantage if we abstain from generalisations and inductions for awhile, and devote ourselves to the more elementary processes of the gathering and sifting of facts. After all, this latter occupation is really harder than the weaving and spinning of theories, and it was not without some justice that Cullen could say in the introduction to his "First Lines" that "there are more false facts than false opinions in physic."

Green-street, W.

ON CERTAIN CASES OF

DISEASE OF THE CENTRAL NERVOUS SYSTEM IN WHICH NO NAKED-EYE CHANGES ARE FOUND AT THE POST-MORTEM EXAMINATION.

By SEYMOUR J. SHARKEY, M.B., F.R.C.P.,
ASSISTANT-PHYSICIAN AND JOINT LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

F. B——, aged six years, was admitted into St. Thomas's Hospital under the care of Dr. Payne on August 26th, and died on August 31st, 1882. The boy was an only child, and his mother was suffering from rheumatism at the time of his birth. His family and personal history was otherwise unimportant. He had never been ill in any way until six weeks before admission to the hospital, when he had a fall and bruised his forehead. His nose bled profusely at the time and at intervals for some days afterwards. The accident appeared, however, to have no effect upon his health. About a week later he was bitten by a dog on the left arm; the wound was cauterised although the animal was not mad. He was said to have been irritable and fretful after this, but otherwise well, and nothing of any importance was noticed until a week before he came to the hospital, when his legs gave way under him, his manner was somewhat foolish, his speech became affected, and he lost control over his evacuations.

On admission he was found to be a well-nourished boy, totally unable to stand or walk, or even to remain sitting upright when placed in that position, although he moved his legs in bed. He had considerable loss of power in his hands and arms, and although able to move them he could only do so in a clumsy, fumbling manner, which was especially evident when he tried to feed himself. There was no loss of sensation and no tenderness or swelling along the spine. The pupils were equal and acted well to light and to accommodation. There were no tremors. The patellar and plantar reflexes were absent, the cremasteric normal. No ankle clonus. The tongue was protruded straight and was covered with a white fur. The evacuations were occasionally passed in bed. The heart and lungs were normal. Urine 1030, acid, lithates deposited, no albumen. Temperature 98·8° F. The mind was clear, but the boy was somewhat dull.

---

[1] Fifth edition, 1884, p. 677.

August 29th.—Patient very restless, and vomiting frequently; deglutition appeared to be difficult, and was followed by gurgling in the throat. He complained of pain in the right knee and of feeling as if a string was tied round his right thigh. Opthalmoscopic examination showed some haze round the discs, but no swelling nor any tortuous vessels.—30th: Patient easier; less restless.—31st: Irritable and fretful; cried when touched, and refused food. Swallowing seemed to be difficult, and the boy was unable to expectorate the mucus which collected in the respiratory passages. He died the same day. The temperature while the patient was in hospital never exceeded 99·2° F. A careful post-mortem examination revealed nothing which could account for death. All the organs appeared perfectly healthy, nor was there the slightest trace of disease of the central nervous system.

While I held the post of resident assistant-physician at St. Thomas's Hospital I had the opportunity of observing all the medical cases which were admitted into that institution for more than three years. I was then struck with the comparatively large number of persons who died with symptoms pointing to disease of the central nervous system, in whom the post-mortem examination disclosed no naked-eye phenomena sufficient to account for the fatal result. I was not then pathologist, and my time was too occupied to allow me to undertake what seemed likely to prove a lengthened investigation. Later, however, the opportunity was afforded me by the case related in this paper of endeavouring to unravel what, to me at any rate, was a mystery. I had followed the case clinically and seen that the prominent symptoms were those of motor paralysis of a very generalised character. I determined to harden and examine microscopically the principal regions of the brain and spinal cord, disease of which usually gives rise to motor troubles. The parts examined were: (1) The lumbar; (2) the dorsal; (3) the cervical regions of the spinal cord; (4) the medulla oblongata; (5) the corpus striatum with the external and internal capsules; (6) the parietal convolutions. The result was as follows:—

1. *Lumbar region of cord.*—The only thing which could be considered pathological in this region was the presence of a slight excess of nuclei.

2. *Dorsal region.*—Here there was some vascular distension, and a slight over-abundance of nuclei.

3. *Cervical region.*—In this region there were again found too many nuclei both in the grey and white matter, and an excess of leucocytes in some of the vessels. The nerve cells in this as in the other regions of the cord were healthy.

4. *Medulla oblongata.*—The changes here were similar to those in the various regions of the cord below, and must be looked upon as unlikely to have given rise to serious results.

5. *Parietal convolutions.*—Vessels were somewhat distended, and there was a general increase of nuclei. Here and there accumulations of leucocytes were seen in the interior of vessels and in their coats; but they were neither frequent nor striking in point of size.

6. *Corpus striatum and internal and external capsules.*—It was on this portion of the central nervous system that the brunt of the disease had fallen, and it presented very marked evidences of inflammation. These were:—(*a*) Distension of vessels and of the perivascular spaces. (*b*) The field of the microscope presented a network of small vessels filled with leucocytes, the white matter of the external and internal capsules being the regions most strikingly altered; and where the external capsule lies upon the corpus striatum a deep border of leucocytes was seen. (*c*) All through the tissues composing the basal ganglia a large number of white corpuscles were observed aggregated in the spaces round the nerve cells and elsewhere.

The results of the microscopic examination of the central nervous system show that the patient died of an acute inflammation, affecting most markedly the basal ganglia, but distributed to a certain extent over a much wider area. A pretty general motor paralysis or paresis was the most prominent symptom in the case, and the position of the principal lesion would well account for this. For in the internal capsule run not only the afferent, but also the efferent strands connecting the convolutions with the whole body. Why a lesion sufficient to impede motor impulses should leave the sensory ones free to pass is not known; but it is a matter of frequent observation that disease of the central nervous system gives rise less easily to anæsthesia than to paralysis, and that the former is more likely to prove a transitory phenomenon than the latter.

Generalisations should not be made from single cases, but nevertheless it is often useful to found hypotheses upon them; for facts subsequently ascertained can be more easily brought to bear upon definitely formulated propositions. Looking, then, at those cases which from the clinical point of view appear to be diseases of the central nervous system, but which yield so-called "negative" post-mortem results, and seeing that, although varying to a certain extent, they present many points of general similarity, the hypotheses I would frame are the following. That wide-spread inflammatory processes may affect the central nervous system, and even prove rapidly fatal, without producing any characteristic naked-eye changes; that in such cases particular portions of the cerebro-spinal system may be more intensely affected than others, and that differences in the clinical phenomena depend upon such localisations; that cases in which the brunt of the disease falls upon parts situated above the pons Varolii are not extremely rare, although they have not received much attention from clinical observers or from pathologists.

The state of opinion on the matter in question will be understood by a perusal of the following quotations:—Reynolds's System of Medicine, vol. ii., article on Cerebritis: "It is probable that general inflammation of the brain never exists alone, but that it is invariably associated with meningitis." "Of uncomplicated cerebritis we have no knowledge." In Quain's Dictionary of Medicine, Mr. Jonathan Hutchinson writes: "It may perhaps be doubted whether the occurrence of diffuse inflammation of the brain substance as an acute disease has as yet been proved, excepting as a result of wounds." "Such a condition of diffuse encephalitis may exist without there being any visible changes in the brain." Wilks' Diseases of the Nervous System: "A general cerebritis, although not so evident in a post-mortem examination, is probably not infrequent; it would be associated, in all probability, with an inflammation of the membranes, and therefore a meningo-cerebritis would be the more appropriate term." In Wilks and Moxon's Pathology, in speaking of diffused inflammation of the brain, the authors say: "This probably happens much more frequently than we recognise after death." In *Brain* for April, 1885, Bristowe writes: "Simple inflammation of the surface, or even of the substance, of the brain no doubt subsides, leaving little or no clinical trace of its pre-existence; and, probably, this is of more common occurrence than most of us suspect." The very interesting article from which these words are quoted is entitled "Cases of Recovery from Symptoms pointing to the Presence of Progressive Organic Cerebral Disease," and the bearing of the present paper on that subject is obvious. In Robert's Handbook of Medicine, sixth edition, p. 890, we read: "Cerebritis is *described* as diffuse or general, and local. The former does not imply that the whole brain is implicated, which is never the case, but merely that there is extensive inflammation of the superficial grey matter, this condition being only associated with meningitis, and evidenced by redness, softening, and adhesion to the pia mater when this is stripped off."

In my search for literature on this subject, I found a monograph by Dr. Charles Elam on "Cerebria and other Diseases of the Brain," published in 1872. Cerebria he defines as "acute, idiopathic, diffused inflammation of the entire brain substance, uncomplicated with meningitis." He calls it "a disease hitherto unrecognised and undescribed, the very existence of which has been formally denied, and one which presents many very remarkable and instructive phenomena." Dr. Elam quotes many authorities on diseases of the brain to show that cerebria is practically an unrecognised pathological condition. Among those cited are Sir Thomas Watson, Aitken, Abercrombie, Bastian, Russell Reynolds, Virchow, and Hayem. Speaking of the symptoms of cerebria, he says: "It is uniform in its commencement and its termination. It begins with vomiting and ends with death. The intermediate phenomena are not very striking, and the duration is from thirty-six hours to twelve days." "In cerebria none of those active symptoms present themselves. They only occur when meningitis is present. There is no coma properly so called. The faculties are oppressed and benumbed, but not entirely lost until the patient is almost in articulo."

It is quite clear from these extracts that Dr. Elam recognised that there were cases which presented a peculiar train of symptoms in which the autopsy revealed what he believed to be a simple cerebritis, uncomplicated with meningitis. And he was probably right in his conclusions, although microscopical evidence of inflammation is not given in most of his cases. In the case which I have described the prominent phenomena were motor paralyses, while marked mental disorder was absent. Such a condition corresponds with the comparative freedom of the convolutions from inflammation and the serious implication of the basal ganglia. In other cases in which nothing has been evident on naked-eye examination, delirium, coma, or other signs of derangement of the higher centres have been observed during life. And it is not improbable that such cases, if examined microscopically, might have shown a special localisation of the disease in the cerebral cortex. Some patients who have presented symptoms very like those observed in the fatal cases have recovered even when they appeared almost certain to succumb. If the pathological processes going on in their central nervous systems resembled those found in the case recorded in this paper, the favourable result is far from unintelligible. For the patient died from the effects of inflammation which, though intense, had produced no actual destruction of nerve tissue; and there seems no reason why the abnormal vascular phenomena should not under favourable circumstances recede and leave the brain as healthy as a lung is often left after an attack of acute pneumonia.

It must not be supposed that I pretend to explain all cases which present obscure clinical phenomena, apparently referable to brain disease, by supposing that the central nervous system is the seat of diffuse inflammatory changes, which the naked eye cannot appreciate. No doubt other causes, such as poisons circulating in the blood, or possibly mere molecular alterations in the nerve tissues, may produce similar clinical phenomena and fatal results without the intervention of inflammation. I merely ask the question, to which further observations must supply an answer in the affirmative or negative,—Do a considerable number of these cases depend upon simple inflammation of the substance of the brain, so-called cerebritis?

Portland-place, W.

RECOVERY OF GOOD SIGHT AFTER TWENTY YEARS' BLINDNESS.

BY GEORGE E. WALKER, F.R.C.S. ENG.,
SURGEON TO ST. PAUL'S EYE AND EAR HOSPITAL, AND TO THE SCHOOL FOR THE INDIGENT BLIND.

ACCUSTOMED as I have been, during some dozen years' practice of the operation, to the great benefits resulting from the severance of adhesions of the iris to the cornea, I confess that the case which I now relate has astonished me not a little.

L. N——, a girl aged nineteen years and three months, was admitted to the School for the Indigent Blind on the 22nd of April, 1884. Her right eye showed all the cornea, except a narrow rim round the margin, as one dense leucoma to which the iris was universally adherent. Of course this was hopeless. The left, in the central lower part, showed a dense leucoma, which shaded off rather abruptly into a fainter one just above, the whole leucoma having a diameter about half that of the cornea. The iris was adherent to the central part of the leucoma, except at the inner side, where a little of the pupillary edge had escaped, so that a very small pin-hole pupil was left; but as it was behind the leucoma and could only be seen sideways, it was not available for vision, and the girl said that she could see no better with the left than with the right eye, nor could she count fingers with either, but had only perception of light.

Thinking that I might give the left eye enough sight to enable her to move about without knocking against chairs and tables, I suggested to her and her father the propriety of treatment; but when they found out an operation was required, I received a prompt negative. At last the father consented that the girl should please herself, but it was not until November that she asked me to operate on her. On the 22nd I attacked the upper part of the adhesion in the way described in THE LANCET of Jan. 31st, p. 197, gaining a considerable increase of pupil. She suffered somewhat from the chloroform, and consented very reluctantly to the second operation, by which, on Dec. 10th, the severance of the upper limb was completed. On Jan. 6th I divided the lower limb at one sweep, although it was very broad; and on the 13th I cut the little bit remaining on the outer side. She was so averse to this last operation that I had to pretend an anger which I did not feel, and almost compel her to submit. One would have expected that the great benefit which accrued most markedly after each operation would have made her eager to submit, but the contrary was the case. Her first sensation after the admission of light into her eye was one of profound horror. She says now that when she first became conscious of sight, and therefore to some degree of space, her feeling was like that of one who looks over a precipice and fears that he will be impelled to throw himself down, and she at the time bitterly repented her consent to be taken out of the darkness which all her life thus far had enshrouded her. By this time, however, the leucoma had cleared up, especially in the upper part, and we found that she had a good-sized pupil, elongated from side to side, the upper, lower, and outer edge ragged from the cuts, whilst the inner presented the normal curve. I had hitherto thought it most probable that the lens had been destroyed, but now I found it existent and transparent, and on testing the eye (Jan. 28th) discovered that the long tension of the imprisoned iris had produced a myopia requiring a 15 D. glass for its correction. The wearing of this speedily caused a change in her state of mind, and she soon ceased to regret her loss of blindness. Under the affectionate tuition of a fellow patient she learned her letters in a day, and to read in a week. Of course this was all the easier from her ability to read with her fingers by Moon's types. Like as occurred in the little boy whose case is described in THE LANCET of Jan. 31st, 1885, a filament of uveal exudation joins the lower edge of the pupil to the cornea, and I shall divide this if I have reason to believe that it keeps up, in any material degree, the over-nutrition of the leucoma. This, however, now deprived of the large blood-supply given to it by the almost universal adherence of the iris, has cleared up greatly, the upper part being almost transparent, and her vision is now (March 2nd) $\frac{6}{40}$, and she reads pretty easily Jaeger 10, and with some little difficulty Jaeger 8—that is, print about the size of "leading article" type.

The main element of the surprise which I have experienced over this case is the retention of visual acuity by the retina under the twenty years' deprivation of light. I see so many examples to the contrary in the persons who present themselves at the Blind School—as, for example, in cases of neglected cataract, as well as in the more familiar instance of squint, which produces the amblyopia *ex inopsia* of the older writers,—that I was not prepared to find that in this girl the retina had preserved its sensitiveness so well; for all the want of acuteness now present may safely be debited to the opalescence of the cornea, which still remains. As this, however, is plainly decreasing, I trust that the eye may further improve. Another interesting fact is that the muscular tissue of the iris shows itself to be quite lively, as it responds promptly both to myotics and mydriatics.

I think now that I have said enough to show that this class of case—a more numerous class, probably, than that of cataract—is susceptible, even in the more formidable instances, of beneficial treatment, and that on the whole we may expect results at least as satisfactory as in other grave diseases of the eye.

Liverpool.

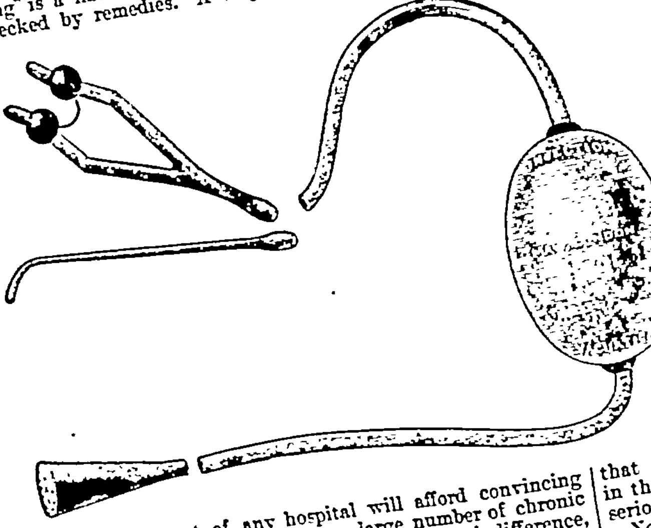
SOUTHPORT INFIRMARY.—The memorial stone of a children's ward to be annexed to this institution was laid on the 30th ult. The new building contains a ward which will accommodate nine cots, allowing each a cubical air space of about 1045 ft., and a "sun-bath," 24 ft. by 7 ft., with glazed sides and roof. The extension when completed will be opened free of debt.

NEW AURAL INFLATOR, EVACUATOR, AND INJECTOR.

WITH REMARKS ON THE TREATMENT OF COMMON AURAL DISEASES.

BY J. WARD COUSINS, M.D. LOND., F.R.C.S.,
SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL AND TO THE PORTSMOUTH AND SOUTH HANTS EYE AND EAR INFIRMARY.

COMMON aural disorders are now receiving far more attention than at any former period, and the day is approaching when, by early diagnosis and treatment, their disastrous sequelæ will be greatly diminished both in number and severity. Scientific methods are taking the place of the old-fashioned and routine treatment by syringing and counter-irritation; still, notwithstanding the all-round improvement that has fortunately occurred, the risk of neglecting the incipient stages of aural derangement has not yet received the general recognition which it is entitled to obtain. Parents too often regard diseases of the ear as trifling ailments which can be cured by ordinary domestic remedies. They treat very lightly deafness in their children, and flatter themselves with the false assurance that the disorder will pass away in time. A fetid discharge from the ear causes them very little anxiety, believing that "the running" is a natural method of relief which ought not to be checked by remedies. A very brief attendance in the aural department of any hospital will afford convincing evidence of my assertion, that a large number of chronic diseases of this class can be fairly attributed to indifference, and that permanent injury to the organ of hearing is frequently the outcome of ignorance and neglect during the early stages of the disorder.



The new aural inflator represented in the engraving is a contrivance designed to fulfil several important purposes in the practice of every-day aural surgery, and it is, in fact, a combination of several instruments, admitting of many useful applications. 1. It serves for inflating the middle ear as an ordinary Politzer's bag. 2. It can be used as an evacuator for the withdrawal of fluid by the Eustachian tube; or as a pneumatic tractor applied to the external auditory canal. 3. It can be employed also for the injection of medicated air charged with the vapour of deodorisers or other volatile fluids. When the instrument is to be applied for tubal inflation, the nasal piece should be adapted to the orifice of the nostrils by means of the wire loop which unites the vulcanite balls. The Eustachian catheter may be substituted for the nasal piece in those cases in which it is desirable to operate upon one ear only. The hand ball is especially fitted with very small valves and a central recoil spring. The end of one of the tubes attached to it must be fixed on the nasal piece for inflation, the end of the other tube for evacuation. Very gentle compression of the hand ball is sufficient for the withdrawal of fluid from the Eustachian tube and tympanic cavity; but the bag must be forcibly and rapidly manipulated for successful inflation. When medicated air is to be injected, the fluid selected must be dropped upon the pledget of cotton-wool placed in the conical vulcanite receptacle, which should then be adjusted on the end of the injecting tube. By the action of the hand ball the air is drawn through the perforated lid, and thus charged with vapour.

Now, it has been often asserted, and perhaps not without some truth, that aural surgery is both tedious and troublesome in practice; on the other hand, it must be admitted that there is no class of minor surgical operations which yields in the long run more satisfactory results. The success which follows the early treatment of catarrh of the middle ear by inflation is very gratifying to the practitioner, and sometimes astonishing to the patient. Already the timely application of politzerisation has done much to reduce the frequency of permanent deafness, and this simple and invaluable method of tubal inflation is fortunately serviceable in many forms of aural disease, and also in association with other important methods of treatment. Even in cases of long closure of the Eustachian tube and collapse of the tympanic membrane, it sometimes succeeds in restoring the normal communication between the tympanum and the pharynx, and this reopening of the tube is soon followed by great improvement in the hearing power. Sometimes the air-douche produces temporary deafness with a sensation of fulness and singing in the ears, but these symptoms gradually subside as the air confined in the tympanum becomes absorbed. This increased tension is especially liable to occur whenever the inflator is used too frequently, or with too much force; it can, however, be relieved at once by using my instrument, and evacuating the imprisoned air by simply reversing the action of the hand ball.

The gentle action of the evacuator is also useful under many other conditions. In young children suffering from earache the bag may be employed for the withdrawal of pent-up fluid into the pharynx. In acute suppurative inflammation of the middle ear, with bulging of the tympanic membrane, evacuation in this way may sometimes succeed, preventing the spontaneous rupture of the drum and removing the necessity of puncture. In chronic aural catarrh attended with deafness and tinnitus aurium the treatment by inflation may often be combined with evacuation with very excellent results. In many of these cases the Eustachian tube is narrowed and blocked with secretion, at the same time the contents of the tympanum are altered in structure and covered by a layer of thick and tenacious mucus. The air-douche alone is of little service. It aggravates the aural discomfort by increasing the abnormal pressure within the cavity, or else it fails to dislodge the pent-up secretion by the tube, so that the membrana tympani becomes unduly tense, and in this condition a repetition of the operation may cause serious injury.

Now, the treatment by alternate inflation and evacuation of the tympanum is certainly theoretically sound, and in my hands it has proved of great benefit in many chronic cases. It promotes the discharge of the inspissated secretion into the pharynx and aids in maintaining the drainage of the cavity. By the injection of air the mucus is disturbed from its position, and by reversing the action of the hand ball of my instrument, it can then be drawn into the tube, and its passage to the pharynx greatly accelerated. This double action is also capable of exerting a salutary influence over the bony chain. The mobility of the ossicles has long been impaired by the morbid condition of the tympanum, but by gently and repeatedly agitating them in both directions, their adhesions to each other are loosened, and their normal oscillation is re-established by which alone vibrations can be transmitted from the drum to the fluid within the internal ear. But the instrument can be used for many other purposes in aural surgery. The injecting tube can be readily connected with Ker's inhaler for the application of chloride of ammonia vapour, in cases of disorder of the mucous passages attended with profuse secretion. The injection of air charged with volatile vapours, such as carbolic acid, creasote, alcohol, iodine, eucalyptus, and other substances, is suggested as an auxiliary measure in chronic middle ear catarrh, requiring more active treatment than the air-douche, and also as a substitute for the injection of fluids into the tympanum.

After the failure of milder measures, however, in cases of obstinate tubal obstruction and thickening of the nasopharynx, the injection of warm solutions into the tympanum has been followed by considerable and even permanent relief. Mr. George Field expresses a decided opinion upon the value of this treatment, and considers "that the injection of appropriately selected warm fluids not only renders the Eustachian tube pervious, but prevents the accumulation of inspissated mucus in the tympanum." When solutions are employed for this purpose, the application of the handball evacuator after the operation will at all times prove of material assistance, for by its action the diffusion of the fluid is secured over the whole mucous lining and its final escape from the cavity promoted, mingled with the elements of secretion. In chronic cases also of collapsed and adherent membrane the indiarubber tube may be introduced into the external auditory canal and the instrument used as an exhauster for the purpose of drawing out the drum, and it thus acts as a substitute for the "pneumatic tractor" recently suggested by Dr. Woakes. The injection of deodorising vapour will be found especially valuable in cases of perforation and chronic otorrhœa—used, of course, in combination with astringent applications and persistent attention to aural cleanliness. By this treatment the patency of the drain tube of the tympanum is maintained, at the same time injected fluids and purulent secretions are blown out through the perforation, which would otherwise be retained in the cavity. It moreover powerfully aids in destroying the fetid odour which is constantly emitted with the discharge, and assists in promoting a cleanly state of the aural surfaces, which, after all, is the essential element of the treatment. All chronic suppurative diseases of the middle ear demand frequent modifications of treatment, and the persevering use of some form of antiseptic for a considerable period. In many cases the otorrhœa is soon checked by the regular employment of astringent solutions; but it often happens that, notwithstanding a marked improvement in the secretion, the distressing fetor continues, kept up by a localised disease of the tympanum, which involves the periosteum, and sometimes the bone itself. It is under these conditions that the vapour treatment is suggested as a valuable auxiliary to other remedies. The injection of medicated air causes no aural irritation, and it can be performed by the patient himself many times during the day as a substitute for other local applications.

In conclusion, I beg to submit my contrivance to the criticism of the profession, trusting that by its convertibility it will prove useful in the treatment of many common aural disorders. The instrument is very neatly made by Messrs. Maw, Son, and Thompson, and it can be obtained from them, together with a second hand ball and extra joint used by me to facilitate the operation of alternate inflation and evacuation of the tympanum. These additions are very convenient, as they obviate the necessity of shifting the tubes, and thus save both time and trouble. Care must be taken to attach one hand ball by the injecting tube and the other by the evacuating tube.

Southsea.

NOTE ON THE

TREATMENT OF URETHRAL GLEET BY MEDICATED METAL BOUGIES.[1]

By T. J. HUDSON, M.D., L.R.C.P. Lond.,
LATE SENIOR RESIDENT MEDICAL OFFICER, LEEDS PUBLIC DISPENSARY.

Chronic inflammation of the urethral mucous membrane or of the glands along its course is rarely benefited by oral medication, usually the reverse, and local applications as commonly carried out often fail us. During the last four years over eighty cases have come under my notice and been treated as follows. The urethral discharge having lasted beyond ten or twelve weeks from the initial gonorrhœal attack, the patient is placed on a hard bed or couch and a No. 4 Brodie's solid bulbous metal bougie, anointed with carbolic oil (1 in 20), is passed into the bladder, which has been previously emptied. Silver instruments should be used, as they are unacted on by chemical substances. If this procedure proves easy and is unaccompanied with much spasm or pain, the instrument is kept in ten minutes and the patient told not to urinate for some hours after. Unless much irritation or scalding result (when a longer interval is to be allowed), in four days' time a No. 6 instrument, anointed with resin ointment and iodoform (2 drachms to the ounce), is passed, and at once changed for a No. 8 or 10, which is kept in some twenty minutes. In another four days a No. 12, and then No. 14, are passed, the latter being the largest size used, and rather heavy, and kept in half an hour. If after a week's interval great improvement does not result, the same size is passed, again covered with iodide of sulphur ointment diluted to one-half with benzoated lard (animal fats penetrating better than the petroleum bases), and kept in from half an hour to two hours. In some of the most chronic and yet successful cases it was thus kept in from four to five hours at a stretch.

Over fifty of the cases were thus entirely cured, many of several years' duration and treated by other methods. The remainder either passed out of sight after one or two instrumentations or had also drugs by the mouth, usually sandal-wood oil and iodide of potash, with cinchona or tincture of cantharides with tincture of iron; while others showing a marked gouty, rheumatic, or strumous diathesis as the principal factor in keeping up the discharge had constitutional treatment as well as local. The ages ranged from seventeen to forty years. No bad results followed beyond a fleeting epididymitis in one case from the iodide of sulphur ointment being fresh and too strong, and at times temporary slight incontinence. A suspensory bandage was enjoined throughout the treatment, but rarely abstinence from stimulants other than spirits. The average duration of treatment was from four to five weeks.

I am aware that the plan of passing medicated instruments down the urethra in these cases is an old one, but usually they are withdrawn at once or almost directly. Such formerly was my practice, and effected little permanent benefit, the cases soon relapsing. The good result obtained, which is lasting, is, I believe, due to the long contact of the bougie and its medicament with the urethral canal. The cause of the long-continued discharge is, apart from stricture (which was present in but five of the above cases), mostly due to the spasmodic contraction of the urethral muscular and elastic fibres, reflex in character, which prevents the scattered patches of ulcerated or abraded mucous membrane from healing. Now, when the urethra is thus brought to the extreme limit of distension, and kept so for a sufficient period, this muscular action is paralysed and ceases to act, irritability being removed; analogous to the condition of the sphincter ani when dilated for fissure, in both cases some tearing of muscular or elastic fibre probably occurring.

The medicament also acts, when kept in contact for some time with the secreting surface or glands, as a stimulator, astringent, and healer, which continues *till at least* the next micturition. A germicidal effect probably also occurs in the less chronic cases, since Neisser has described a micrococcus in urethritis, rod-shaped, and rather like the bacteria of ulcerative balanitic pus. The medicament should be put thickly on to the bougie, and if slight narrowing of the meatus occurs, a slit in it is useful, or the ointment gets removed and fails to reach the affected parts.

In the form of ointment it is much more beneficial than as a liquid preparation, not excluding balsam copaivæ or dilute iron solutions. That the good results are not alone due to it—i.e., the medicament—is shown by a gum elastic solid bougie of similar size when anointed and passed doing little and often no lasting good, the patient often remarking that the "heavy" instrument did him most benefit. Now, this I take to be due to the fact that the former is somewhat compressible and compressed with effect by the urethra and yields. Not so the latter; for I found that the elastic one was often held tightly, however long kept in; the metal one, however, paralyses all resistance, and is quite free after a brief interval in the passage. It, moreover, acts with greater efficiency on irregularity, induration, and narrowing of the urethral canal and its submucous tissue, on fine granulations or warts, discharging lacunar, follicular, or mucous glandular abscesses, or merely the chronic blennorrhœal inflammation at either the fossa navicularis, beginning of membranous or (most often) bulbous portions of the urethra; also when shreds of glairy mucus are secreted due to relaxed and chronically inflamed prostate, and not alone curable by open blisters for some weeks to the perineum. The part affected is often indicated by fixed local increased sensibility on instrumentation.

---

[1] Abstract of a paper read before the Leeds and West Riding Medical and Chirurgical Society.

Injections I never use, for it is very problematical if they ever reach the whole, or even a greater part, of the morbid mucous lining in these old cases, which is, however, effectually done by the above method. The same applies to the urethral irrigators once in vogue, three cases of their use by patients having been seen, and none being cured thereby. Iodoform and other soluble bougies, up to six inches in length, are often much objected to in private practice, from their objectionable smell, &c. They do not dilate the passage appreciably, and, though often formerly used, have never in my hands *per se* cured a case of long-standing gleet.

COCAINE IN OPERATIONS FOR FISTULOUS CANALS.[1]

BY J. G. BARFORD, L.R.C.P.L., M.R.C.S.

THE following case is interesting from two points of view: (1) as indicating the risk a patient appears to run in moving from a healthy country district to town to have a surgical operation performed, however skilfully done; and (2) the great value of cocaine as a local anæsthetic, even when considerable flesh wounds have to be inflicted, in cases where it is undesirable to administer a general anæsthetic from some idiosyncrasy in the patient.

A country clergyman, whose home is situate in an open, bracing, and exceptionally healthy locality, 600 feet above the sea, was the subject of hæmorrhoids, for which he was advised to place himself under the care of one of the best-known specialists for this affection. He went from the pure air of the country into a private surgical home for the purpose of having the hæmorrhoids removed. No difficulty was experienced in the operation, and the inner surface of the rectum healed readily, and remains sound up to the present time. But a few days after the operation some untoward constitutional symptoms presented themselves. The temperature rose to 104° and general febrile disturbance ensued. In a few days, pain, tenderness, and swelling displayed themselves along the perineum to the scrotum, and in due course a considerable accumulation of pus was apparent. A free incision was made, and with the discharge of pus the general symptoms improved. There was also another small accumulation of pus in the inner surface of the buttock, running up in the direction of the rectum. This, too, was freely opened. At the end of the fifth week from the operation the patient was removed in one of Ridding's invalid carriages into the pure air of the country. His general symptoms had somewhat improved; but the discharge from the wounds was very sanious, and far from healthy-looking; he was not making the progress a patient should do under the circumstances. His condition was one of evident septic infection. Two sinuses remained at the points of suppuration, about the depth of half an ordinary surgical probe, and leading to what appeared to be soft and easily broken-down tissue, threatening to work their way towards the rectum, or it might be into the urethra. The patient's condition at this time did not justify further operative interference. At the end of two months from the operation two other sinuses were formed in the perineum between the anus and the scrotum. One of these healed spontaneously, as, indeed, a sinus occasionally does. Two of the other sinuses communicated with each other. At the end of three months from the removal of the hæmorrhoids the patient's constitutional condition had sufficiently improved to justify further surgical interference, and it was decided to lay the sinuses freely open. The patient had, however, on previous occasions proved to be such a bad subject for general anæsthetics, that their administration was thought unjustifiable. I therefore decided to use cocaine to destroy the sensibility of the part. Some small plugs of cotton-wool were saturated with a 20 per cent. solution of cocaine, supplied by Mr. Martindale of Cavendish-street, and these were inserted into the sinuses, one plug in each, and allowed to remain for a quarter of an hour. They were then removed, and each sinus laid freely open with an ordinary bistoury and director. No pain whatever was felt by the patient in laying open two of the sinuses, the patient not knowing even when the incisions were being made. In laying the third sinus freely open a considerable portion of skin had to be cut through, and while the bistoury was passing through the skin the patient displayed some consciousness of it. The skin is evidently not so ready an absorbent of cocaine as either mucous membrane or an abraded surface. If I had again to use cocaine in an operation involving the skin, I should apply a little liquid blister to abrade the surface before the application of the cocaine. Exactly one drachm of the 20 per cent. solution was used. In operation with cocaine there is but little hæmorrhage, thus it is not unlikely to become a valuable remedy to restrain bleeding.

A CASE OF POPLITEAL ANEURYSM; OPERATION; CURE; REMARKS.

(Under the care of Mr. RICHARD BARWELL.)

As Mr. Barwell says in his remarks, statistics have not yet been accumulated showing whether ligature of the femoral artery for popliteal aneurysm as at present carried out is as safe a method of treatment as compression of the femoral, either digital or by weight. There is no doubt that a large number of cases which are cured by compression are not published, and the experience of some hospital surgeons is that they have seldom been called upon to ligature the femoral artery for aneurysm, having found the former method sufficient. We would refer our readers to the cases of aneurysm published in THE LANCET of May 30th, p. 983, and also to the discussion on a paper read before the Clinical Society on April 24th, and published in THE LANCET, May 2nd, p. 799.

Benjamin S——, aged forty, boatswain, was admitted into Robertson ward on February 17th, 1885. The man is well and strongly built, of healthy family, and is at the present time in good health. He has never had syphilis, and is temperate. Four years ago he noticed a swelling behind the right knee, which caused considerable stiffness of the limb and some pain, but he took little notice of it for two years. He then underwent some treatment; the limb was bandaged, and an instrument (probably a tourniquet) was applied to the thigh for a fortnight, but no benefit resulted. The tumour remained, however, of much the same size until the beginning of the year, when he had a good deal of climbing on ladders to do, since which it rapidly increased. The leg being now very stiff and cumbersome, he obtained leave of absence and entered the hospital.

On examination a tumour with expansile pulsation was found in the left popliteal space; it was ovoid in form, measuring 3 in. in the vertical and 2½ in. in the transverse direction; pulsation without tumefaction could be felt beyond these limits. All the characteristics of aneurysm with the exception of bruit were present; the sac lay pretty close to the skin, and had evidently but little clot within it. Flexion of the knee carried as far as seemed safe produced no alteration in the force of the pulsations. Mr. Barwell stated that in consequence of the absence of clot in the sac, and also in view of the fact that pressure had already failed, any good results from such treatment could hardly be expected, but he thought it only right that it should be tried. A conical-shaped bag, filled with four pounds of shot, was suspended by a horizontal support over the bed, so that when placed in position its whole weight would fall on the required part. The man, very intelligent and amenable, was shown how to hold this bag upon the femoral artery at the groin, where course and position were marked by a narrow strip of plaster, which he also as a substitute for the injection of fluids into the tympanum.

After the failure of milder measures, however, in cases of obstinate tubal obstruction and thickening of the naso-pharynx, the injection of warm solutions into the tympanum has been followed by considerable and even permanent relief. Mr. George Field expresses a decided opinion upon the value of this treatment, and considers "that the injection of appropriately selected warm fluids not only renders the Eustachian tube pervious, but prevents the accumulation of inspissated mucus in the tympanum." When solutions are employed for this purpose, the application of the hand-ball evacuator after the operation will at all times prove of material assistance, for by its action the diffusion of the fluid is secured over the whole mucous lining and its final escape from the cavity promoted, mingled with the elements of secretion. In chronic cases also of collapsed and adherent membrane the indiarubber tube may be introduced into the external auditory canal and the instrument used as an exhauster for the purpose of drawing out the drum, and it thus acts as a substitute for the "pneumatic tractor" recently suggested by Dr. Woakes. The injection of deodorising vapour will be found especially valuable in cases of perforation and chronic otorrhœa—used, of course, in combination with astringent applications and persistent attention to aural cleanliness. By this treatment the patency of the drain tube of the tympanum is maintained, at the same time injected fluids and purulent secretions are blown out through the perforation, which would otherwise be retained in the cavity. It moreover powerfully aids in destroying the fetid odour which is constantly emitted with the discharge, and assists in promoting a cleanly state of the aural surfaces, which, after all, is the essential element of the treatment. All chronic suppurative diseases of the middle ear demand frequent modifications of treatment, and the persevering use of some form of antiseptic for a considerable period. In many cases the otorrhœa is soon checked by the regular employment of astringent solutions; but it often happens that, notwithstanding a marked improvement in the secretion, the distressing fetor continues, kept up by a localised disease of the tympanum, which involves the periosteum, and sometimes the bone itself. It is under these conditions that the vapour treatment is suggested as a valuable auxiliary to other remedies. The injection of medicated air causes no aural irritation, and it can be performed by the patient himself many times during the day as a substitute for other local applications.

In conclusion, I beg to submit my contrivance to the criticism of the profession, trusting that by its convertibility it will prove useful in the treatment of many common aural disorders. The instrument is very neatly made by Messrs. Maw, Son, and Thompson, and it can be obtained from them, together with a second hand ball and extra joint used by me to facilitate the operation of alternate inflation and evacuation of the tympanum. These additions are very convenient, as they obviate the necessity of shifting the tubes, and thus save both time and trouble. Care must be taken to attach one hand ball by the injecting tube and the other by the evacuating tube.

Southsea.

NOTE ON THE

TREATMENT OF URETHRAL GLEET BY MEDICATED METAL BOUGIES.[1]

By T. J. HUDSON, M.D., L.R.C.P. LOND.,
LATE SENIOR RESIDENT MEDICAL OFFICER, LEEDS PUBLIC DISPENSARY.

CHRONIC *inflammation of the urethral mucous membrane* or of the glands along its course is rarely benefited by oral medication, usually the reverse, and local applications as commonly carried out often fail us. During the last four years over eighty cases have come under my notice and been treated as follows. The urethral discharge having lasted beyond ten or twelve weeks from the initial gonorrhœal attack, the patient is placed on a hard bed or couch and a No. 4 Brodie's solid bulbous metal bougie, anointed with carbolic oil (1 in 20), is passed into the bladder, which has been previously emptied. Silver instruments should be used, as they are unacted on by chemical substances. If this procedure proves easy and is unaccompanied with much spasm or pain, the instrument is kept in ten minutes and the patient told not to urinate for some hours after. Unless much irritation or scalding result (when a longer interval is to be allowed), in four days' time a No. 6 instrument, anointed with resin ointment and iodoform (2 drachms to the ounce), is passed, and at once changed for a No. 8 or 10, which is kept in some twenty minutes. In another four days a No. 12, and then No. 14, are passed, the latter being the largest size used, and rather heavy, and kept in half an hour. If after a week's interval great improvement does not result, the same size is passed, again covered with iodide of sulphur ointment diluted to one-half with benzoated lard (animal fats penetrating better than the petroleum bases), and kept in from half an hour to two hours. In some of the most chronic and yet successful cases it was thus kept in from four to five hours at a stretch.

Over fifty of the cases were thus entirely cured, many of several years' duration and treated by other methods. The remainder either passed out of sight after one or two instrumentations or had also drugs by the mouth, usually sandal-wood oil and iodide of potash, with cinchona or tincture of cantharides with tincture of iron; while others showing a marked gouty, rheumatic, or strumous diathesis as the principal factor in keeping up the discharge had constitutional treatment as well as local. The ages ranged from seventeen to forty years. No bad results followed beyond a fleeting epididymitis in one case from the iodide of sulphur ointment being fresh and too strong, and at times temporary slight incontinence. A suspensory bandage was enjoined throughout the treatment, but rarely abstinence from stimulants other than spirits. The average duration of treatment was from four to five weeks.

I am aware that the plan of passing medicated instruments down the urethra in these cases is an old one, but usually they are withdrawn at once or almost directly. Such formerly was my practice, and effected little permanent benefit, the cases soon relapsing. The good result obtained, which is lasting, is, I believe, due to the long contact of the bougie and its medicament with the urethral canal. The cause of the long-continued discharge is, apart from stricture (which was present in but five of the above cases), mostly due to the spasmodic contraction of the urethral muscular and elastic fibres, reflex in character, which prevents the scattered patches of ulcerated or abraded mucous membrane from healing. Now, when the urethra is thus brought to the extreme limit of distension, and kept so for a sufficient period, this muscular action is paralysed and ceases to act, irritability being removed; analogous to the condition of the sphincter ani when dilated for fissure, in both cases some tearing of muscular or elastic fibre probably occurring.

The medicament also acts, when kept in contact for some time with the secreting surface or glands, as a stimulator, astringent, and healer, which continues till at least the next micturition. A germicidal effect probably also occurs in the less chronic cases, since Neisser has described a micrococcus in urethritis, rod-shaped, and rather like the bacteria of ulcerative balanitic pus. The medicament should be put thickly on to the bougie, and if slight narrowing of the meatus occurs, a slit in it is useful, or the ointment gets removed and fails to reach the affected parts.

In the form of ointment it is much more beneficial than as a liquid preparation, not excluding balsam copaivæ or dilute iron solutions. That the good results are not alone due to it—i.e., the medicament—is shown by a gum elastic solid bougie of similar size when anointed and passed doing little and often no lasting good, the patient often remarking that the "heavy" instrument did him most benefit. Now, this I *take to be due to the fact that the former* is somewhat compressible and compressed with effect by the urethra and yields. Not so the latter; for I found that the elastic one was often held tightly, however long kept in; the metal one, however, paralyses all resistance, and is quite free after a brief interval in the passage. It, moreover, acts with greater efficiency on irregularity, induration, and narrowing of the urethral canal and its submucous tissue, on fine granulations or warts, discharging lacunar, follicular, or mucous glandular abscesses, or merely the chronic blennorrhœal inflammation at either the fossa navicularis, beginning of membranous or (most often) bulbous portions of the urethra; also when shreds of glairy mucus are secreted due to relaxed and chronically inflamed prostate, and not alone curable by open blisters for some weeks to the perineum. The part affected is often indicated by fixed local increased sensibility on instrumentation.

---

[1] Abstract of a paper read before the Leeds and West Riding Medical and Chirurgical Society.

Injections I never use, for it is very problematical if they ever reach the whole, or even a greater part, of the morbid mucous lining in these old cases, which is, however, effectually done by the above method. The same applies to the urethral irrigators once in vogue, three cases of their use by patients having been seen, and none being cured thereby. Iodoform and other soluble bougies, up to six inches in length, are often much objected to in private practice, from their objectionable smell, &c. They do not dilate the passage appreciably, and, though often formerly used, have never in my hands *per se* cured a case of long-standing gleet.

COCAINE IN OPERATIONS FOR FISTULOUS CANALS.[1]

BY J. G. BARFORD, L.R.C.P.L., M.R.C.S.

THE following case is interesting from two points of view: (1) as indicating the risk a patient appears to run in moving from a healthy country district to town to have a surgical operation performed, however skilfully done; and (2) the great value of cocaine as a local anæsthetic, even when considerable flesh wounds have to be inflicted, in cases where it is undesirable to administer a general anæsthetic from some idiosyncrasy in the patient.

A country clergyman, whose home is situate in an open, bracing, and exceptionally healthy locality, 600 feet above the sea, was the subject of hæmorrhoids, for which he was advised to place himself under the care of one of the best-known specialists for this affection. He went from the pure air of the country into a private surgical home for the purpose of having the hæmorrhoids removed. No difficulty was experienced in the operation, and the inner surface of the rectum healed readily, and remains sound up to the present time. But a few days after the operation some untoward constitutional symptoms presented themselves. The temperature rose to 104° and general febrile disturbance ensued. In a few days, pain, tenderness, and swelling displayed themselves along the perineum to the scrotum, and in due course a considerable accumulation of pus was apparent. A free incision was made, and with the discharge of pus the general symptoms improved. There was also another small accumulation of pus in the inner surface of the buttock, running up in the direction of the rectum. This, too, was freely opened. At the end of the fifth week from the operation the patient was removed in one of idding's invalid carriages into the pure air of the country. His general symptoms had somewhat improved; but the discharge from the wounds was very sanious, and far from healthy-looking; he was not making the progress a patient should do under the circumstances. His condition was one of evident septic infection. Two sinuses remained at the points of suppuration, about the depth of half an ordinary surgical probe, and leading to what appeared to be soft and easily broken-down tissue, threatening to work their way towards the rectum, or it might be into the urethra. The patient's condition at this time did not justify further operative interference. At the end of two months from the operation two other sinuses were formed in the perineum between the anus and the scrotum. One of these healed spontaneously, as, indeed, a sinus occasionally does. Two of the other sinuses communicated with each other. At the end of three months from the removal of the hæmorrhoids the patient's constitutional condition had sufficiently improved to justify further surgical interference, and it was decided to lay the sinuses freely open. The patient had, however, on previous occasions proved to be such a bad subject for general anæsthetics, that their administration was thought unjustifiable. I therefore decided to use cocaine to destroy the sensibility of the part. Some small plugs of cotton-wool were saturated with a 20 per cent. solution of cocaine, supplied by Mr. Martindale of Cavendish-street, and these were inserted into the sinuses, one plug in each, and allowed to remain for a quarter of an hour. They were then removed, and each sinus laid freely open with an ordinary bistoury and director. No pain whatever was felt by the patient in laying open two of the sinuses, the patient not knowing even when the incisions were being made. In laying the third sinus freely open a considerable portion of skin had to be cut through, and while the bistoury was passing through the skin the patient displayed some consciousness of it. The skin is evidently not so ready an absorbent of cocaine as either mucous membrane or an abraded surface. If I had again to use cocaine in an operation involving the skin, I should apply a little liquid blister to abrade the surface before the application of the cocaine. Exactly one drachm of the 20 per cent. solution was used. In operation with cocaine there is but little hæmorrhage, thus it is not unlikely to become a valuable remedy to restrain bleeding.

CHARING-CROSS HOSPITAL.

A CASE OF POPLITEAL ANEURYSM; OPERATION; CURE; REMARKS.

(Under the care of Mr. RICHARD BARWELL.)

As Mr. Barwell says in his remarks, statistics have not yet been accumulated showing whether ligature of the femoral artery for popliteal aneurysm as at present carried out is as safe a method of treatment as compression of the femoral, either digital or by weight. There is no doubt that a large number of cases which are cured by compression are not published, and the experience of some hospital surgeons is that they have seldom been called upon to ligature the femoral artery for aneurysm, having found the former method sufficient. We would refer our readers to the cases of aneurysm published in THE LANCET of May 30th, p. 983, and also to the discussion on a paper read before the Clinical Society on April 24th, and published in THE LANCET, May 2nd, p. 799.

Benjamin S——, aged forty, boatswain, was admitted into Robertson ward on February 17th, 1885. The man is well and strongly built, of healthy family, and is at the present time in good health. He has never had syphilis, and is temperate. Four years ago he noticed a swelling behind the right knee, which caused considerable stiffness of the limb and some pain, but he took little notice of it for two years. He then underwent some treatment; the limb was bandaged, and an instrument (probably a tourniquet) was applied to the thigh for a fortnight, but no benefit resulted. The tumour remained, however, of much the same size until the beginning of the year, when he had a good deal of climbing on ladders to do, since which it rapidly increased. The leg being now very stiff and cumbersome, he obtained leave of absence and entered the hospital.

On examination a tumour with expansile pulsation was found in the left popliteal space: it was ovoid in form, measuring 3 in. in the vertical and 2½ in. in the transverse direction; pulsation without tumefaction could be felt beyond these limits. All the characteristics of aneurysm with the exception of bruit were present; the sac lay pretty close to the skin, and had evidently but little clot within it. Flexion of the knee carried as far as seemed safe produced no alteration in the force of the pulsations. Mr. Barwell stated that in consequence of the absence of clot in the sac, and also in view of the fact that pressure had already failed, any good results from such treatment could hardly be expected, but he thought it only right that it should be tried. A conical-shaped bag, filled with four pounds of shot, was suspended by a horizontal support over the bed, so that when placed in position its whole weight would fall on the required part. The man, very intelligent and amenable, was shown how to hold this bag upon the femoral artery at the groin, whose course and position were marked by a narrow strip of plaster, which he could plainly feel with the finger. The pressure of the bag entirely annihilated pulsation at the aneurysm, and he was enjoined to continue it as long as it could be borne.

Feb. 21st.—Pressure from 8 A.M. to 12; from 1 P.M. to 5 P.M.; from 5.30 to 8.30: 11 hours.

22nd.—Pressure from 6 A.M. to 12; from 1.30 P.M. to 6 P.M.; from 6.30 to 10 P.M.: 14 hours.

23rd.—Pressure from 6.30 A.M. to 12; from 1 P.M. to 5.30 P.M.; from 6 to 9.30: 13½ hours.

24th.—Pressure from 6.30 A.M. to 12.

On careful examination of the aneurysm Mr. Barwell could find no sign of improvement; indeed, the tumour appeared a little larger laterally. The groin, although the skin was quite normal, was slightly tender on pressure. The man stated that his leave only lasted up to a certain date, and he begged that an operation might be performed, so that he could get back to his ship, otherwise he would lose his appointment.

26th.—Mr. Barwell tied the superficial femoral with an ox aorta ligature at the apex of Scarpa's space, turning aside the saphenous vein and the inner edge of the sartorius; singularly little blood came from the incision. The tumour became immediately pulseless, harder, and smaller. A drainage-tube and carbolic gauze dressing were used.

27th.—A little venous oozing had come through the bandage; dressings changed; drainage-tube shortened. The man has had no pain. General temperature normal; that of both limbs equal, 98·4°.

March 3rd.—Wound healed, with exception of a passage for the drainage-tube, which was removed. The aneurysm has had no pulsation in it since the operation; it is rapidly decreasing in size, and is perfectly hard.

14th.—The patient has been begging for some days to be dismissed; to-day he was discharged. It was thought by some observers, but negatived by others, that there was some slight pulsation in the posterior tibial artery.

Remarks by Mr. Barwell.—The treatment of aneurysm by pressure was studied and perfected at a period of surgery when the result of all operations, but, perhaps, more especially that of deligation, was singularly unfavourable, or, to say the least, uncertain. Cleanliness and purity in the treatment of wounds were but little studied; the use of silk ligatures establishing a suppurating tract communicating with an artery ulcerating in close proximity to a vein exposed to risks which at this day seem terrible to contemplate. Now, incised, clean, and non-putrefying wounds such as we make to reach the vessel heal at once, and our ligatures no longer cause suppuration. Future statistics, sufficient materials for which have not yet accumulated, will show whether deligation as now practised is or is not as safe or safer than proximal pressure. Of all forms of ligature I hold that which being flat does not divide any vascular coats to be by far the safest. Of those made from the tendon of the kangaroo's tail I have neither personal experience nor the means of collecting numbers. Of those made from the ox aorta I can, I believe, give all the cases—viz.:

Number of cases.		Number of vessels tied.
1	Innominate	1
2	Carotid alone	2
4	Carotid and subclavian	8
2	Iliac[1]...	2
1	Common femoral	1
8	Superficial femoral	9
1	Brachial	1
—		—
19		24

In none of these cases did any secondary hæmorrhage occur from the place of deligation.[2] Mr. Thomson's patient (deligation of the innominate) died by hæmorrhage from an ulcerated opening in the subclavian; no other patient has succumbed. Thus in nineteen patients twenty-four vessels have been tied with the ox aorta ligature, and with that one exception of innominate deligation (which has never yet proved successful) no death has occurred; no amputation or other infelicitous result. It will be observed that among the deligations of the above table are the largest vessels that can be tied; the results may be contrasted with those of proximal pressure for popliteal aneurysm. I collected two years ago[3] all published cases—viz., 148. Of these 6·8 per cent. either died or submitted to amputation. The cases collected from six hospitals showed even less favourable results—viz., 8·8 per cent. either underwent amputation or died. Moreover, of the whole number, those gathered from journals and those taken from hospital records, 49·5 per cent. failed. If we consider the confinement, the anxiety, the pain that patients thus treated undergo; if we consider the disappointment when failure is announced; and, above all, when we consider the death-rate,—we shall probably find it desirable to reconsider an idea which has taken root with us, that proximal pressure is a safer and a milder treatment than a carefully performed and scientifically conducted deligation.

WEST KENT HOSPITAL, MAIDSTONE.

RAPIDLY-GROWING SARCOMA OF THIGH; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. Knowles.)

Alfred W——, aged twenty-seven, married, came to the out-patient department, on Jan. 7th, with the following history:—The patient is a farrier. A week ago he was kicked by a horse on the outer side of the left leg, a little above the knee-joint. Some swelling of the part took place at once, accompanied by a good deal of pain. He had been able to work since; the swelling, he thought, had gone down a little, but he still complained of aching pain over the site of the injury. On examining the limb, a diffused swelling occupied the lower fourth of the outer side of the left thigh; smooth, immovable, and apparently deeply seated; firm, but pitting slightly on pressure; slight ecchymosis of skin; no inflammatory appearance, and the circulation in the leg below unaffected by it. The patient was unwilling to come into the house; he attended on the 14th, and again on the 21st, when he was persuaded to come in.

On admission, Jan. 22nd, he was a pale strumous-looking man, fairly well nourished; tongue furred; bowels confined. Morning temperature 99°, evening 100°. Lung sounds normal; heart sounds normal; hepatic and splenic dulness normal; axillary and inguinal glands about the size of peas. Urine: specific gravity 1012, acid; excess of phosphates; no albumen.

Family History.—Is one of nine children. One brother had been in Guy's Hospital for pulpy disease of synovial membrane of the knee-joint, and the joint was excised. Amputation of the thigh was subsequently performed; another died in infancy of fits. The rest, with parents, are living and well. The swelling has considerably increased in size and encroaches upon the anterior surface of the thigh; the lower margin is prominent and well defined; the upper is lost in the general thickness of the thigh; distinct veins cross the tumour; skin freely movable over it; over the most prominent part there was a sense of fluctuation. The left inguinal glands enlarged to the size of an olive, but not hardened. The circumference of the left thigh at the lower third measured seventeen inches and a half; right thigh ten inches and a half. There was some œdema of the left foot and slight flexion of the leg on the thigh.

Jan. 26th.—A distinct sense of resistance felt above Poupart's ligament, with tenderness on pressure; slight œdema of the thigh; circumference 18½ in.

Feb. 2nd.—Superficial abdominal veins over the left side distinct. A well-defined mass can now be easily mapped out occupying the left iliac fossa, reaching as high as the anterior superior spine, and encroaching upon the hypogastric region. Dulness and sense of resistance felt over the back of the left lumbar region; and corresponding to the position of the left kidney is an elastic ovoid swelling, 2 in. by 1 in., somewhat painful on pressure, and with marked sense of fluctuation. Circumference of thigh 19⅜ in.

12th.—Patient getting thin; anæmia more marked; complains of some difficulty in swallowing; troublesome cough, with scanty glairy expectoration, dulness over the base of the right lung, with coarse râles and bronchophony. Morning temperature 98°, evening 100·5°; pulse 80, small and weak. Some epistaxis.

19th.—Emaciation marked; cough more troublesome;

---

[1] One of these was the external. In one it was doubtful whether the external or the common iliac was tied.

[2] In Mr. Thomson's case of deligation of the innominate, secondary hæmorrhage arose from suppuration of the wound opening into the subclavian a considerable distance from the ligature. During my operation on the common femoral a free gush of blood, probably from an enlarged superficial circumflex, occurred as the outer part of the sheath was opened; it ceased when the ligature was tightened, but recurred in seven days, and again seven days later. It was definitively suppressed by tying the vessel above and below, dividing it between the ligatures.

[3] Encyclopædia of Surgery, Art. Aneurysm, vol. ii., p. 463.

coarse râles over both the lungs except apices; night sweats; pulse very feeble, and respiration laboured. Circumference of left thigh 19½ in.; right thigh 10¼ in. The growth now involves the popliteal space, and extends upwards as high as the great trochanter. Some thinning of the integuments over the more prominent part of the tumour, with distinct fluctuation; no pulsation; the superficial veins of the thigh and the left side of the abdomen more engorged and increased œdema of the leg and thigh; no increase of size or hardness of the inguinal glands; in the abdomen the area of dulness and resistance extended as high as the umbilicus, and a little beyond the median line, it being a well-defined, smooth, hard mass; increased resistance felt over back of left lumbar region, and an increase of the swelling occupying the position of the left kidney to three inches and a half by two inches (the long axis parallel to spine); urine gave the same reactions as before.

26th.—Patient extremely emaciated; bedsores over right hip and knee-joint; he takes very little nourishment on account of great difficulty in swallowing; death occurred the following day.

Post-mortem (Feb. 28th).—Rigor mortis present. The left thigh looked about double the size of the right, there being a difference of 9¼ in. in the circumference. An incision from the great trochanter to the external condyle of the femur, and carried down to the bone, revealed the following: The whole of the soft parts of the thigh were infiltrated with a pulpy reddish-brown granular-looking mass, which could be easily scraped away with the finger, not encapsuled and apparently limited below by the attachment of the fascia to the bony prominences around the knee-joint. There was another form of growth which presented a different naked-eye appearance; it was limited in extent, and arranged in lobules of various sizes, greyish-white in colour, and of firm consistence, exactly resembling a section of the brain. Several small *blood-cysts* permeated the growth. The periosteum was smooth, and as far as the finger could ascertain the bone was not affected. An incision along the anterior surface of the thigh showed the same characters. On opening the abdomen, the peritoneum and sigmoid flexure of the colon were seen to be displaced upwards by a large mass, which occupied the whole of the left iliac fossa; this mass was encapsuled and of varying consistence, it spread over the posterior abdominal wall, and reached as high as the pelvis of the kidney; that portion between the kidney and posterior abdominal wall, and which corresponded to the external swelling, was *semi-fluid* in consistence. A section through the mass above Poupart's ligament presented the same characters as the primary growth. Two encapsuled tumours, each the size of an orange, were situated on the under surface of the diaphragm, one between the layers of omentum on the greater curvature of the stomach and two others near the crest of the ilium on the right side. Liver: Enlarged (weight sixty ounces), pale, capsule tense, parenchyma soft and easily broke down under the finger, several greyish-white spots about the size of a pin's head scattered throughout the organ. Pancreas: Entirely filled with a firm yellowish-white mass, the gland felt like a piece of indiarubber. Kidneys: Pale, otherwise normal. Spleen: Capsule lax, pulp very soft, of a bluish colour on section, turning a brick-red colour on exposure to air. Lungs: Some pleuritic adhesions over both; a few ounces of fluid in the right pleura; both lungs thickly studded with firm, greyish-white deposits, varying in size from a pea to a bean; both bases œdematous. Anterior and posterior mediastina contained numerous encapsuled masses of the soft pulpy form, and the bronchial glands around the roots of the lungs were involved in a mass similar in appearance to that deposited in the lungs and pancreas. Under the microscope it was seen to be a small round-celled sarcoma. The secondary deposits showed a few elongated spindle-shaped cells, but beyond these all the specimens examined presented great uniformity of appearance.

Remarks by MR. KNOWLES.—This case offers a good illustration of the high degree of malignancy of round-celled sarcoma. The rapidity and extent of its growth, terminating fatally within two months, show the necessity of making an early diagnosis in cases where surgical interference is contemplated. When first seen it was very difficult to say whether the swelling was due to an extravasation of blood or a new growth. It did not appear to be connected with the bone, although from its position the question of sarcoma was entertained from the first. A fortnight later, when admitted into the house, there could be no doubt as to its malignant nature; and four days after admission, and before permission to amputate the limb had been obtained, the deposit was detected above Poupart's ligament. It would seem that an extravasation of blood took place at the time of the injury, and that this, instead of being followed by resolution or suppuration, as might have been expected in a strumous diathesis, assumed malignant characters. The growth was twice aspirated with a fine needle, and each time a little blood was withdrawn, but no sarcomatous cells were detected under the *microscope*.

LIVERPOOL ROYAL INFIRMARY.

CASES OF ABDOMINAL SECTION; CONVALESCENT; REMARKS.

(Under the care of DR. WALLACE.)

FOR the notes of these cases, to which reference was made in our last issue, we are indebted to Mr. Laimbeer.

CASE 1. *Salpingitis.*—J. S——, aged twenty-eight, has been ill four years. She was admitted to hospital in July, 1884, and has been under treatment since. She suffers from pains in the pelvis, and is unable to work, lately even to move in bed. Operated on, March 4th, 1885. Both tubes were removed, but both ovaries left; the right tube was enlarged and thickened; both were congested. The patient made an *uninterrupted* recovery, and is now able to walk well.

CASE 2. *Hysterectomy, &c.: Multiple Fibroids.*—C. C. A——, aged forty, a widow, has been under treatment since July, 1882, for fibroids of the uterus; she is getting worse, and cannot work on account of pain. Operated on, March 10th, 1885. Abdominal section and removal of pedunculated fibroid; also of the uterus, with a mass of intramural fibroids. The cervix formed the stump, and was brought to the abdominal wall in the median line. The serre-nœud was used. The wire of the serre-nœud cut through on April 11th, the patient doing well.

CASE 3. *Adherent Dermoid Cyst.*—L. McR——, aged twenty-two, noticed a swelling of the abdomen at Christmas last. Operated on, March 25th; abdominal section. The cyst was universally adherent. It was cleared of its contents (hair and cheesy matter resembling pus), and a drainage-tube left in. The cyst has now contracted to a small sinus, about two inches and a half long. The patient's general health is good.

CASE 4. *Ovarian Cystoma.*—E. McK——, aged twenty-eight, noticed an abdominal swelling six months ago. Operated on, March 26th. A multilocular ovarian cyst of the right side was removed. The patient's recovery was slightly retarded by the formation of an abscess in the abdominal wall. Is now quite well.

CASE 5. *Disease of Oviducts and Ovaries (?).*—M. J. B——, aged thirty-one, has been under treatment for more than twelve months with very severe pain and reflex ovarian symptoms, the patient occasionally losing all self-control, and threatening to commit suicide; profuse menorrhagia.—Nov. 14th, 1884: Abdominal section. The ovaries contained small cysts. The cysts were pricked; the Fallopian tubes were stilettoed. Uninterrupted recovery. No improvement after this operation.—April 2nd, 1885: Abdominal section done again. Both ovaries and tubes taken away. The patient made an uninterrupted recovery. She feels quite well. She menstruated for forty-eight hours three days after the operation.

Remarks by DR. WALLACE.—Cases 1 and 5 were both subjects of intense neuroses, the former being able to grow a phantom tumour under inspection of abdomen, for which there was nothing to account except salpingitis; while the latter was twice operated upon by abdominal section, for such intense pain in lower abdomen as drove her frantic and made her threaten suicide. Both tubes were dilated and filled with serous fluid; the ovaries were apparently healthy. On the first operation a piece was cut out of the right oviduct; the left burst on attempting to detach it from adhesion to the left pelvic wall. No relief followed. Ovaries and tubes were next removed. Her neuroses have vanished. Why excision of the oviducts in the first case gave complete relief, the ovaries being left behind, while in the latter case opening the oviducts, taking off pressure of distension and draining—all true surgical procedures—gave no relief, I am not prepared to venture an opinion. The mental impression in neurotic patients is sometimes so great that opening the abdomen and doing nothing except draining cures them. Spaying women must always be a repulsive proceeding, and it is one very apt to be abused. The cases of hysterectomy and dermoid cyst cured by drainage are interesting in their way.

Medical Societies.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

At a meeting of the Society on the 13th ult.,

Dr. E. F. Willoughby read a paper on Variola and the Varioloid Diseases of Animals. He said that a number of animals—as the sheep, goat, camel, swine, and according to some the dog—are subject to diseases resembling in all their phenomena that known as small-pox in man, and which may therefore be called variola humana, ovina, caprina, camelina, &c. They are all highly infectious to animals of the particular species to which they belong, attended by high fever, a general vesicular or pustular eruption, and great danger to life; not communicable to animals of other species except by direct inoculation, and then producing a local affection only, with little constitutional disturbance and no danger to life. One attack, however induced, confers immunity against the particular disease, but they are not mutually protective. Horse-pox and cow-pox differ in several essential features from the foregoing; they are purely local affections, unattended by much fever or any danger, are not infectious, but, though said to appear spontaneously in rare instances, are communicable only by inoculation, when they confer immunity not only against subsequent inoculations, but also against the infection or inoculation of human small-pox. Though experiment shows that they can be inoculated on any part of the body of horses and cattle of either sex and of any age, the so-called spontaneous cases are always seen to occur on the heels of horses, the udders of milk-cows, and the lips of sucking calves. On these facts two opposed theories have been built: one, which may be called the French doctrine, though accepted by Böllinger in Germany and Fleming in this country, is that there are two orders of variolæ, in one of which the virus is, as Fleming expresses it, "volatile," and in the other "fixed." In other words, while inoculation with small-pox protects man against small-pox, and inoculation with sheep-pox protects the sheep against sheep-pox, though small-pox does not protect against sheep-pox, nor sheep-pox against small-pox, yet cow-pox and horse-pox confer immunity not only against one another, but against a totally unlike disease—namely, small-pox. The other, and certainly the correct view, held by the best authorities in England and Germany, except those above mentioned and by Dr. Warlomont, is that while the variolæ proper are so many distinct specific diseases, peculiar to the respective animals, though capable of being communicated in a modified form to others by direct inoculation, cow-pox and horse-pox are not independent diseases, but merely instances of the cultivation of human small-pox in the organism of another animal. Since "vaccination" has been proposed as a prophylactic measure against sheep-pox, and other suggestions of a like kind have been made from ignorance of the true relations of these diseases, it is of the highest importance that the law of immunity should be clearly understood. It may be expressed in four theses: 1. One attack of variola of the kind proper to any animal protects the individual against subsequent infection or inoculation with the same. 2. Inoculation of any animal with the virus of its own variola produces a milder form of the same disease, but affords a protection similar to that conferred by an attack acquired by ordinary infection. 3. Any variola inoculated in an animal other than that whose variola it is, gives rise to a peculiarly modified form of the disease, attended by little constitutional disturbance, merely local congestion, and no danger to life; such modified disease being no longer communicable to any other animal of the same or of different species except by direct inoculation. 4. This modified disease affords a considerable degree of immunity against infection by any means whatever with the variola whence it was derived, either to the animal whose variola was the original source of it, or to others capable of being infected in any way thereby.—In the discussion which followed, the President, Drs. Renner, Pringle, Gordon, C.B., Murray, and Mr. Shirley Murphy took part.

ACADEMY OF MEDICINE IN IRELAND.

Sloughing of the Rectum.—Acute Pneumonia.

At a meeting of the Medical Section on Feb. 27th,

Dr. W. M. A. Wright read a paper on a case of Sloughing of the Rectum. The patient, a lady aged sixty-five, who had had piles for the last twenty years, but who was in other respects quite healthy, who led an active out-door life, and whose bowels were stated to have always acted most regularly, became ill on Jan. 22nd, 1884. When visited on the following day she said her piles had become inflamed, and on examination a ring of them was found external to the anus, nipped by the sphincter, much congested, very tender, and irreducible. Anodyne treatment was adopted locally and generally. On the 25th profuse leucorrhœa set in, and on the 27th complete retention of urine, which lasted for eight days. On the 28th diarrhœa came on, and the skin over the gluteus maximus on both sides of the anus, but especially the right, became very tense, red, glazed, and erysipelatous looking. On Feb. 1st an external opening formed on the right side, about an inch from the anus, and almost all the fæces began to pass through it; by the 4th power over the bladder was regained, and the inflammation had sufficiently subsided to allow of a rectal examination, when an enormous mass of fæces was found, broken up by the finger, and partially removed by an enema; daily enemata removed the entire mass by the 10th. When the fæcal tumour was partially got rid of, the internal opening was made out clearly, about one inch and an half up the gut on the right side, and as large as a half-crown piece. On the 14th a secondary abscess, with odourless pus, opened into the fistula, after which recovery was uninterrupted. Dr. Wright remarked that the inflammation of the piles and the sloughing of the rectum were undoubtedly caused by the pressure of the fæcal mass (just as a fœtal head may cause sloughing of the vagina in the second stage of a tedious labour); the periproctitis and erysipeloid condition of the skin over the buttock were caused by the escape of the fæces into the cellular tissue of the ischio-rectal fossa. No cases quite analogous were found recorded. The retention of urine was probably after. A vaginal examination would have revealed the cause sooner, but could not have altered the treatment. The patient, when last seen, nine months after the attack, had quite recovered; the fistula was completely closed, the bowels regular, and no symptoms of stricture present. Operative interference was refused when it became practicable.—Dr. Finny referred to a case under his care in which a vaginal examination revealed the true cause of the symptoms to be a mass of impacted fæces in the rectum.—The President mentioned that the late Sir Dominic Corrigan used to lay down that when a diarrhœa obstinately continued, the rectum should always be examined, and it would often be found that there was either fæcal accumulation or cancerous ulceration.—Dr. Wright briefly replied.

Dr. Walter Smith read notes of four cases of Acute Pneumonia occurring in members of the same family at or about the same time. Case 1. Boy, aged sixteen years, first seen on third day of illness. A very severe case, terminating fatally on the morning of the ninth day. The respiration was rarely below 60, and there was constant delirium. Right lung first affected; then the left lung involved. Case 2. Boy, aged thirteen years, seen on the second day of illness. Pneumonia of base of right lung spreading on fourth day to base of left lung. Crisis on the ninth day, and good recovery. Case 3. The youngest boy, aged seven years, seen on first day of illness. Pneumonia of right base. A mild case terminating by crisis on fourth day. Case 4. An adult sister of these boys had been ailing for some time with a severe cough, but struggled on until obliged to give up. Pneumonia of the left base ending favourably by crisis. The four cases developed within a few days of each other. The chief point of interest, suggested by examples of multiple cases, is their etiology—that is, are they instances (*a*) of epidemic pneumonia; (*b*) of infectious pneumonia imported into a house and spreading from person to person; or (*c*) of pythogenic pneumonia? The sanitary condition of the house in which these patients lived was very indifferent, but the author observed that the report on Acute Pneumonia of the Collective Investigation Record, vol. ii., furnished no ground for asserting that multiple pneumonia is associated with exceptionally bad sanitation.—Surgeon-General De Renzy called attention to the frequency of epidemics of pneumonia in the Punjaub, and believed the disease was of an infectious character.—Dr. W. Wright mentioned two cases parallel to those noted by Dr. Smith.—Dr. J. W. Moore espoused the view that pneumonia should rather be styled pneumonic fever, and thought that a correlation existed between pneumonia and enteric fever as regards prevalence.—Drs. C. F. Moore and Doyle also joined in the discussion, and Dr. Walter Smith replied.

Multiple Exostoses.—Cutaneous Epithelioma.

At a meeting of the Pathological Section on March 13th, Professor Thornley Stoker read a paper on the Pathology of Multiple Exostoses, and exhibited the bones of a skeleton affected by them to a remarkable degree. Most of the bones were engaged, and a great degree of symmetry existed between the outgrowths of opposite sides. The lower extremities presented the most pronounced deformities, and showed the two forms of exostoses which Professor Stoker stated to be more common than is generally supposed, and which he discovered in a great number of persons in whom no previous exciting cause could be traced—that is to say, a growth projecting upwards from the lower part of the internal condyloid ridge of the femur, and one projecting downwards from the internal tuberosity of the tibia. Although these deformities and kindred ones are often begotten of some inflammatory process, the result of injury, syphilis, rheumatism, or such like, he expressed his view that they frequently arise as a result of some hyperactivity in the bone-forming tissues, and without any inflammatory cause. He referred to the objection to any classification of bony growths which divided them into hyperplastic and heteroplastic, as they belong to the connective-tissue group of structures, and are always truly hyperplastic, originating in the connective tissues, even when found in situations and organs the most remote from normal bone. Attention was also drawn to the similarity which exostotic growths show to some of the conditions found in the healthy bones of lower animals, and, when occurring in tendons, to the osseous tendons of birds, and a suggestion was thrown out that such conditions give evidence that disease in many ways resembles a retrograde metamorphosis, and as such is interesting to the morphologist.—The President asked Professor Stoker in what condition did he find the cartilages. Were the larynx and bronchial and tracheal cartilages affected, and did the membranes of the interior of the skull show any tendency to bone deposit?—Professor Bennett said in the cases before the Section there was not a shadow of evidence in favour of any inflammatory process having been the cause of the ossification. Again, the ossification was not in the muscles, but in their sheaths. On the other hand, ossifying myositis rather began by destroying the muscles and then producing ossification of the sheaths. He therefore objected to the term myositis ossificans as descriptive of such a skeleton, because it tacked on a theory not justified by the facts. These went to show that the disease was congenital and started in early life, and that the ossification proceeded in a manner the reverse of that which prevailed in true ossifying myositis, and was not inflammatory. In the skeleton described by Bookey, and preserved in the College Museum, and also in cases recorded by himself (Professor Bennett) and one or two others, the disease commenced in early life, and proceeded slowly along the muscles first, and implicated the bone afterwards. In the present case the disease began in the bone, and grew into the tendons afterwards.—Professor Cunningham observed that an interesting point was the connexion between these pathological changes in bones and morphological changes. Professor Stoker seemed to assume that the changes were always of a degenerative kind. That might be the case in the majority of instances, but frequently they had instances of pathological changes helping the morphological alterations. A change in the habits of an animal sometimes rendered a ligament necessary in the place of a muscle, and then the latter underwent changes which converted it into a ligament. Such changes were distinctly pathological. During the present session in the dissecting-room of Trinity College a young male subject was met with who exhibited these changes on both sides of the body, and to a much greater extent than the specimen handed round, and both Professor Bennett and himself were inclined to think that it was due to some peculiar occupation which had been followed by the individual.—Dr. Foy observed that morphological changes produced by pathological conditions could not always be considered as disadvantageous. The so-called degradation of tissue produced by pathological processes might serve a useful purpose, as was shown in some of the lower animals—a fact first clearly shown by Herbert Spencer in the second part of his work on Biology, published in 1865 and 1867. It was established in the well-known case of the turkey, where the muscle corresponding to one of the human adductors was usually found ossified. That those changes commenced early in life could not, he (Dr. Foy) thought, be questioned, as the period of selection in the protoplasm for minerals must have preceded its differentiation.—Professor Stoker, in reply, said the bronchial and tracheal cartilages were not affected in his specimen, nor were there any signs of ossification in the brain, and the membranes of the latter were not particularly adherent. The cartilages of the joints were singularly perfect, notwithstanding that there were so many changes in the neighbourhood of the joints. The os innominata presented a good deal of bony change, like that which was seen in chronic rheumatic arthritis, but the acetabulum was very little changed. He agreed with Professor Bennett that there was no evidence that the condition in question was the result of inflammation; and he had only used the name to which exception had been taken until a better one was found. He believed that the ossifying process began in the connective tissue of the muscle, and proceeded from the muscle towards the bone, forming a secondary connexion with it. He did not think there was proof of the statement that myositis ossificans was usually congenital. In Dr. Bookey's case, the girl, who died at the age of twenty-six, was known to have been healthy up to the age of five, at which period the changes in her muscles began.

Dr. Ball read a paper on cases of Cutaneous Epithelioma occurring amongst the operatives at a tar distillery. The first case came under notice four years ago, when Dr. Ball removed the front of the scrotum for an epithelioma, which had been preceded by a hard, horny wart. A recurrence took place at the side of the scrotum, not involving the operation cicatrix; this was extirpated two years ago, and since then the patient has remained well. The second case was that of an old man, about eighty years of age, who had an extensive epitheliomatous ulcer on the back of the left hand, which had originated in a wart five or six years previously. On the dorsum of the right hand, and for a distance of about two inches above the wrist, there were numerous hard, horny warts, and similar growths were present on the forehead and nose, although none existed on the parts of the body covered by clothing. The forearm was amputated, but recurrence took place within a few months afterwards, the lymphatic vessels of the extremity being more obviously implicated than the glands. In addition to these two cases, Mr. Story had brought forward a case of epithelioma of the eyelid in a man who had been engaged at the same occupation. From inquiries made at the works, Dr. Ball learned that two others of the operatives had recently been somewhat similarly affected. One had an ulcerated wart on his nose, which had been destroyed by caustic, the cicatrix being still present, and another was stated to have had a large sore cut out of his face; but it was found impossible to trace this case, as none of his fellow-workmen knew what had become of him. The close resemblance between these cases and the soot cancer of Pott indicate that, like it, they owed their origin to long-continued irritation; in fact, it is quite possible that the active chemical agent is identical in both instances. As there are but seventeen men employed in this industry in Dublin, it would appear that the proportion of cases of epithelioma occurring amongst them is very considerable; the numbers are, however, much too small upon which to base statistics. There are but three principal products manufactured at the works in question. First, a light liquid, which is called "naphtha oil," comes over from the stills; then a heavier fluid, called "creasote oil," which the manager kindly informed Dr. Ball contains on an average about 8 per cent. of phenol, and pitch is the residue of the process. The "creasote oil" is the most irritating of these products, and, although, as stated, containing 8 per cent. of carbolic acid, the men wash their hands in it without hesitation. Dr. Ball had recently an opportunity of questioning a man who had been for a number of years engaged in one of the large carbolic acid manufactories in England. On this man's hands there were numerous warts, and he stated that such warts were not uncommon amongst the operatives, even those who only had to deal with the purest and most refined carbolic acid; but he had never known of any cases of cancer occurring amongst the workpeople.—The PRESIDENT observed that the last case showed that irritation of the skin was produced by the new industrial product mentioned. It would be worth inquiring into whether any difference was made by the use of wood or coal tar, and also whether the internal use of carbolic acid was dangerous. It was given in large quantities for many diseases; and they knew that the stomach was an organ which required very little provocation to generate epithelioma.—On the motion of Mr. STORY both specimens were sent to the Committee of Reference.

Professor BENNETT read a paper on Complete Dislocation of the Elbow Outwards.

The Section then adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society, held on March 26th,

Mr. GARRARD exhibited the Knee-joint of a patient whose thigh he had amputated the previous week. The cartilages were almost gone from extension of articular ostitis, the joint was disorganised, and the stump had healed by primary union. The disease was of twenty years' standing.

Mr. THORPE related particulars of an interesting case of Hermaphrodism.

Mr. S. MORTON related the case of a man, aged twenty-four, who had Pneumothorax on the left side, jumping from a dray having caused rupture of the air cells into the pleural cavity. He had been up to that moment in good health—no cough, no wasting, no history of phthisis. Next day the heart was found pushed over to the right side; its apex felt two inches below and one inch to the left of the right nipple. Amphoric resonance was general on the left side, with diaphragm pushed downwards. The patient suffered acute pain with dyspnœa for five days, after which he always said he felt well. In seven weeks the heart had returned to its normal position, after which he had general pleurisy on the same side, followed by effusion. After seventeen weeks he was quite well.

Dr. PORTER showed two cases of Enlarged Spleen. In one case the child, a year and ten months old, had a large hydrocephalic head, with wide fontanelles and all the symptoms of rickets. The spleen was of enormous size, occupying the greater part of the abdominal cavity, but placed obliquely so that the lower end extended to the right iliac region. In the other case the diagnosis was less obvious. The history was one of rapid enlargement since last Christmas, the spleen extending downwards as low as the level of the anterior superior iliac spine, and forwards as far as the middle line, the free anterior border and hilus being felt close to the umbilicus.

Mr. SNELL read a paper on the Implication of the Mastoid Process in Ear Disease. After remarking on the rarity of affection of the process without accompanying ear disease, he alluded to the frequency of discharges from the ear, and of the little heed that patients too frequently bestowed upon them in many cases. Attention was called to the value of incising the drum as a prevention of perforation in some cases. The importance in all cases of providing a free escape of pus by the Eustachian tube and meatus was urged, and the value of cleansing the ear with boracic acid lotion. Referring to the dangerous class of cases in which the interior of the mastoid suppurated and it became necessary to perforate the bone, the steps to be taken were mentioned, and allusion was made to the anatomical structure of the mastoid, and the frequency with which the process is composed of sclerosed, or at all events less pneumatic, tissue.

At a meeting of this Society on April 9th,

Mr. BARBER showed a Testicle which he had removed from a man aged fifty-two, who had been admitted into the infirmary suffering from phlebitis of the right femoral and saphena veins. On examination the right testicle was found to be enlarged and heavy, but quite painless. The man deemed it hardly worth mentioning as it had caused him no uneasiness for four years. Mr. Barber commented on the chronicity of the case, as microscopical examination showed the growth to be of a cancerous nature. The cord was only slightly thickened, and fluid was present in the tunica vaginalis.

Mr. ATKIN exhibited a large Vaginal Tumour for Mr. FAVELL. The woman from whom the tumour had been removed had had symptoms for twenty-four years, three years after her first and only confinement. On section the growth proved to be very succulent, and gangrenous changes were commencing; but on microscopical examination it was seen to be of fibro-cellular nature undergoing mucoid degeneration.

Mr. BALDWIN showed a case of Atheroma of the Heart, in which the right coronary artery was surrounded by an osseous plate, rendering the artery nearly impervious. The specimen was from a man, aged forty-seven, a heavy drinker when young, and who suffered from vague anginal pains over the chest, with a systolic bruit. Death occurred suddenly during an attack. Aortic valves thickened, and very atheromatous.

Dr. HARDWICK read a paper on Hæmoglobinuria, giving particulars of a case under his own care, and showing that a chill was the immediate cause of the occurrence of each attack in this instance, and afterwards remarked upon the accounts of the disease given by Drs. Elliotson, Prout, Watson, G. Harley, G. Johnson, Dickinson, Gull, Murchison, Pavy, Greenhow, Hassall, Habershon, and Stephen Mackenzie; and called attention to the cases of the latter as compared with his own case, which occurred in a lady of fifty-eight, in contradistinction to what is generally the case in adult males.—Dr. Dyson, Dr. Law, Mr. Browning, Mr. Baldwin, and the President joined in the discussion which followed.

At the annual meeting on April 30th the following officers were elected:—President: Mr. R. J. Pye-Smith. Vice-president: Mr. W. A. Garrard. Treasurer: Mr. G. S. Taylor. Secretary: Mr. Simeon Snell. Members to complete Committee: Dr. Law, Dr. Keeling, Dr. Dyson, Dr. Porter, Dr. Martin. Pathological Committee: Mr. C. Atkin, Dr. Gwynne, Dr. S. White, Mr. Baldwin.

On May 13th the annual dinner took place, and was well attended.

MIDLAND MEDICAL SOCIETY.

AN ordinary meeting of the above Society was held on April 23rd, the President, Mr. T. H. Bartleet, F.R.C.S., in the chair.

Mr. SPOFFORTH showed a case of Locomotor Ataxy with Joint Disease. The patient, a man aged forty-nine, had exhibited the usual symptoms of locomotor ataxy for two years before he met with an accident seven months ago. A reaping machine passed up the right leg, over the hip, across the back, and over the left shoulder. He went about for nearly a month after the accident, and was then laid up from swelling in the right knee, attended with great pain. About five weeks after the accident he was admitted into Kidderminster Infirmary. At the present time the right patella is much enlarged and dislocated outwards, and there is considerable effusion in the joint. The circumference of the right knee is eighteen inches, and of the left fourteen inches. The ends of the bones forming the joint are enlarged, and crackling is produced on movement. There is absence of the patellar reflexes, with swaying movements and the Argyll-Robertson pupil.

Mr. BENNETT MAY showed a boy, aged three years and a half, on whom he had successfully performed Thyrotomy for Papilloma of the Larynx. The thyroid cartilage being laid open by vertical incision for the purpose, a mass of soft vascular warty tumours was removed, some by scissors, and others by twisting, nitrate of silver being freely used to the surfaces. Tracheotomy had been performed by Mr. May, a fortnight previously, through an independent incision, and nearly three months elapsed before the tube could be finally discontinued, all attempts being attended by rapid closure of the outer wound and impending suffocation. The difficulty appeared to arise from the trachea becoming choked up with granulation tissue around and above the tube, though at one time relapse of fresh growths or stenosis from cicatricial webbing was feared. The boy had perfectly recovered, being quite free from dyspnœa or cough, and having a good voice. He had steadily improved up to the present time, five months after the operation.

Dr. SUCKLING showed a case of Ideal Paralysis. The patient, a boy aged sixteen, two years previously, after a trivial injury to the left knee, suffered from complete paralysis of the left lower leg. The paralysis supervened suddenly a few days after the injury, and had remained unchanged till within a few weeks ago. When Dr. Suckling saw him the left lower extremity was flaccid and completely paralysed. There was considerable atrophy of the muscles, but general and due to disuse. There were no qualitative electrical changes, and sensation was perfect. The reflexes were slightly excessive. The boy was not hysterical, but was emotional and nervous, of the neurotic type so well described lately by Dr. Allbutt. After being told that he would quickly recover, and after faradisation, he was able to move the limb, and at the present time can walk four miles, to and from the Queen's Hospital, without any support, only being a little awkward in his gait.

Mr. BENNETT MAY exhibited a collection of Calculi from recent operations, two removed by nephro-lithotomy, one by supra-pubic lithotomy, six by litholapaxy, and a number by perineal lithotomy, mostly lateral. Mr. May expressed himself a warm advocate of litholapaxy for the majority of adult patients. He found a No. 15 evacuating tube, if made of thin metal, large enough for fragments of moderate size. The débris of the largest of the six calculi shown weighed thirteen drachms, representing a stone an inch in length. It is of uric acid, and was taken from a gentleman aged sixty-three. After removal of the other calculi, recovery was complete and rapid. Mr. May also showed, on behalf of Mr. Crompton a splendid collection of Calculi, sixty in number, which the latter gentleman had formed during his life, and representing the majority of his operations. Many of the specimens were of great beauty and of large size. They were nearly all removed by lateral lithotomy, and a large proportion from adult and aged patients, with the exception of one which weighed six ounces and a half. The removal of only one of the number had been followed by a fatal result.

Mr. CROMPTON made the following observation on the subject of lithotomy:—"If I were asked what in my opinion was the chief cause of mortality after lithotomy, I should certainly say it was the want of certainty as to the real and free entrance of the knife into the bladder; sometimes, perhaps most frequently, from the knife not being pushed far enough along the grooved staff; sometimes from the staff having receded from, or not having been fairly and fully passed into, the bladder, and the forceps being attempted to be passed into such an unopened bladder, the consequences being too frequently fatal from urinary infiltration."

Reviews and Notices of Books.

The Elements of Pathology. By EDWARD RINDFLEISCH, M.D., Professor of Pathological Anatomy in the University of Würzburg. Translated from the First German Edition by W. H. MERCUR, M.D. Revised by JAMES TYSON, M.D. London: Henry Kimpton. 1885.

THE task of presenting a concise analytical summary of the widely extended field of modern pathological knowledge is no slight one. It could only be undertaken by one who has himself as thorough an acquaintance with the subject with which he has been so long identified as the author of this little book. Professor Rindfleisch has done good service in collating and generalising upon pathological facts and theories. For although in many particulars the incompleteness of knowledge does not at present warrant the formation of general deductions, yet it is good to have, if only for their suggestiveness, the well-considered conclusions at which a leading pathologist feels himself justified in arriving. The book is not, as its author remarks, intended as a text-book, but we venture to think that it may well form the basis of much instruction. The regret is that it is so brief; that where we should have liked detailed argument we have to be content with a few aphorisms. The tone is therefore necessarily dogmatic, for the reader is not in all cases led through the processes of reasoning which the writer has followed. Nevertheless, we have read the book with a pleasure which is sure to be felt by all who do the same. Some idea of the line of treatment pursued may be gathered by a reference to the chief sections into which the subject is divided. Under the general part is included in the first place the "symptoms" which characterise the local outbreak of disease—that is, inflammation and tumour formation, which practically include all the processes concerned in the initial lesions. Then follow sections on the anatomical extension of disease—namely, by metastasis and nervous irritation, with a discussion on fever and cachexia, as the leading "deuteropathic" symptoms. The physiological extension of disease, or "sympathetic" symptoms, comprises, under the head of Vegetative Disturbances, disorders of nutrition, circulation, blood formation, and blood purification, which include the major part of morbid derangements; and under that of Animal Disturbances the various disorders of the nervous system, each and all treated from the physiological standpoint. In the special part Professor Rindfleisch groups all diseases etiologically—the only true ultimate classification; and thus he arrives at five great divisions—viz., (1) traumatic diseases; (2) parasitic and infectious diseases; (3) diseases of evolution—i.e., of defective development and growth; (4) diseases due to overwork; and (5) diseases of involution. Of course, under traumatism is included every variety of injury and irritation, whether operating internally or externally, directly upon the tissues or indirectly through the nervous system.

The result of this mode of treatment, this comprehensive bird's-eye view of the whole domain of morbid processes and their manner of production, is a monograph which possesses the charm of originality combined with lucidity. We may think it premature and too theoretical, but it is at any rate fertile in suggestion; it may be often more dogmatic than is warrantable, but it is at least based on clear and well-defined principles; and, lastly, although we may fail to meet with many new facts, it presents us with the old in a novel light. Hence we welcome the book as one worthy of attention and thought, it being, as the author tells us in the introduction, which concisely sums up its whole purport, based on the attempt "to study the nature of disease in itself, and thereby to separate that which pertains to the cause of disease from that which is due to peculiarities of the diseased organism." The task of translation has been creditably performed.

Surgical Delusions and Follies. A Revision of the Address in Surgery for 1884 of the Medical Society of the State of Pennsylvania. By JOHN B. ROBERTS, A.M., M.D., Professor of Anatomy and Surgery in the Philadelphia Polyclinic. Philadelphia: P. Blakiston, Son, and Co. 1884.

THIS is a vigorous and interesting address, which is well worth reading. Dr. Roberts strongly advocates the use of ether in preference to chloroform, decries styptics for arrest of hæmorrhage, shows the exaggerated importance often attached to a slight or moderate loss of blood, advocates a much freer use of the trephine, early operation for strangulated hernia phlegmonous inflammation, and malignant tumours, proclaims the curability of acute traumatic tetanus, and draws attention to various other "delusions" and "follies." He has not attempted to say anything new, nor have we found anything taught in this address that is novel to any thoughtful surgeon who is abreast of the times. Superstitions and false notions live long, however, and it is well that attention should be prominently directed to them from time to time. Anyone who ventures to address his brethren upon their "delusions" and "follies" should, however, be beyond reproach; and we fear that some of the value of Dr. Roberts' excellent address will be lost from a certain looseness, we had almost said carelessness, of style. Thus, on page 29, while writing of the pathology of compression of the brain, he states, "I cannot believe it to be due to compression or displacement of the brain itself. It is more probable that compression symptoms are the results of encephalitis, due to injury from spicules of the inner table, or to the irritation of intracranial bleeding....... 'Compression of the brain,' as seen after injury, should be translated 'inflammation of the brain.'" This is a view quite at variance with every-day experience. The typical symptoms of "brain compression" are produced immediately upon the receipt of a depressed fracture of the skull and before inflammation can possibly have arisen; while undoubted encephalitis occurs without any of the special signs of "compression." On page 28 we read, "That simple puncture or aspiration of the heart itself is not accompanied by the expected risk to life has also been indicated, though I am not yet prepared to recommend its general adoption for trivial cardiac conditions." We should think not! Because asymmetry of limbs is "of common occurrence," Dr. Roberts would "place no reliance whatever upon measurements of the length of legs to determine the existence or the degree of shortening after fractures of the femur," and yet a little care will enable the surgeon to escape from the error existing asymmetry might lead him into. Long-established and, on the whole, most valuable usages are not to be set aside in this unreasonable fashion. One of the "follies" Dr. Roberts disclaims is the "sponge folly" for absorbing blood from wounds, because of the risk of introducing septic particles into the wound on the sponge; in place of sponges, towels or napkins are recommended. "Perfectly clean surgical sponges are the exception, but clean household towels are the rule." Dr. Roberts, we are sure, knows perfectly well that a so-called clean towel is loaded with septic dust, and is by no means surgically pure or fit to be introduced into a wound, and by the exercise of no uncommon care sponges can be made and kept quite free from dirt in either the general or surgical sense. On page 46 we read, "Adhesive plaster has little or no value in surgery, except for making extension and preventing motion in cases of fracture." This shows quite an inadequate appreciation of the use of well-adjusted plaster. It can accomplish what sutures never can —the uniform firm adaptation of surfaces without traction or tension upon any particular point; in the treatment of the wound after amputation of the breast, for example, it is most valuable, and there are many similar instances where a surgeon skilled in the use of strapping finds it a most useful adjunct to his treatment of a case. We can only refer to similar looseness in recommending full doses of the alkaloids in all cases in which they are given. Dr. Roberts' task, however, was a worthy one; his execution of it, on the whole, is good; but the expenditure of more pains in the preparation of this address would have rendered it more useful in putting an end to surgical "delusions" and "follies" than we dare hope it can be in its present form.

Health Lectures for the People. Illustrated. Fifth Series. Pp. 185. Edinburgh: Macniven and Wallace. 1885.

THIS is the fifth annual series of lectures delivered under the auspices of the Edinburgh Health Society. The lectures appear, as a rule, to be well calculated to further the objects of the Society, which are: "To promote by all means in its power attention to personal and domestic cleanliness, to comfort, self-denial, temperance, and the laws of health generally." Probably the most practically useful paper in this series is one on marketing and cookery, by teachers from the Edinburgh School of Cookery and Domestic Economy. It gives much useful information on the important subjects of how to market, and how to make the best use of the food when bought. These are points on which, unfortunately, sound advice is very much required, not only among the very poor, but among the well-to-do classes, and it is given clearly and intelligibly. It is followed by a lecture, by Mr. Falconer King, on "Food Adulteration," in which some of the more common forms in which sophistication is practised are brought to notice, and the injury to health and iniquitous robbery involved in it are pointed out. Mr. Falconer King appeals to the public to second, in their own interests, the efforts of the public analysts. "If people remain, as they are at present, profoundly apathetic, apparently, as to the purity of the food they consume, all the public analysts that ever were will be insufficient to stamp out the evil; but if these officials be assisted in the discharge of their duties as they ought to be by the public generally, so that transgressors may be detected and punished in such way that adulteration may cease to be profitable, then these worst of rogues will disappear, honest men will come in their place, and we shall soon have what everyone must admit is of the very greatest importance, so far as health and happiness are concerned—an abundant supply of really pure food." "The Bath: How and When to Use it," is also a lecture which, we trust, will be taken to heart by those to whom it is addressed. It brings out the unpleasant fact that public baths and wash-houses have not as yet been self-supporting institutions. In Bradford, Birmingham, Liverpool, and Glasgow they all show a deficit in the receipts. Edinburgh has not yet established public baths, but is about to do so. The Edinburgh Health Society has adopted the very useful plan of printing and distributing leaflets on the more important practical points connected with the improvement of the sanitary condition of the people, and thus bringing these matters to the notice of those for whose benefit they are intended, and who probably would not otherwise have an opportunity of knowing anything about them.

Brain. A Journal of Neurology. Part XXIX. April, 1885. London: Macmillan and Co.

THE opening article of this number is by Dr. Bristowe, and consists of a relation of some interesting cases of Intracranial Disease, with recovery from symptoms pointing to the presence of progressive organic brain affection. Two were cases strongly suggestive of tubercular meningitis, and the third one of symptoms of progressive disease in the neighbourhood of the fourth ventricle, possibly due to a syphilitic lesion, although there was no collateral evidence at all of syphilis. Dr. David Drummond describes the Spinal Lesion in Infantile Paralysis from a case fatal within six or seven hours of the onset; there were very marked inflammatory changes found in the anterior cornua. Dr. W. J. Dodds contributes the first part of a very exhaustive essay upon some Central Affections of Vision; and Dr. Allen Sturge a most elaborate study of the Nerve Phenomena in a case of Anæsthetic Leprosy, in which he suggests several points for further investigation. Dr. W. C. Bentley writes upon the Deep Reflexes in General Paralysis of the Insane, as indicative of implication of the spinal cord. A contribution to cerebral localisation is made in the record of a case of Brachial Monoplegia, due to a limited lesion of the internal capsule; the case is confirmatory of views recently enunciated in these columns by Mr. Victor Horsley. Other cases of interest are contributed by Dr. Sharkey, Mr. Walter Edmunds, and Dr. Suckling. The "critical digest" in this number deals with the Combination of Lateral and Posterior Sclerosis, and is supplied by Dr. Ormerod; and Dr. James Anderson contributes a report on Recent Advances in the Anatomy of the Nervous System.

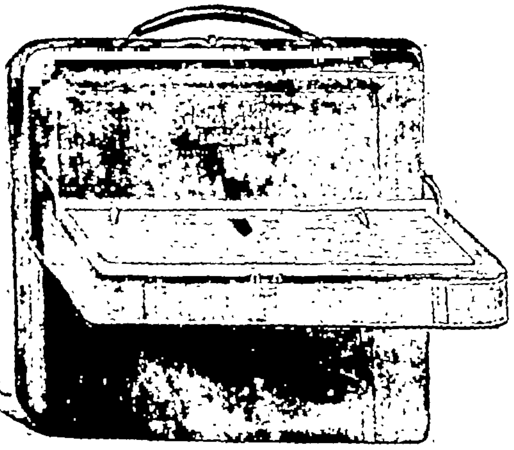
HOSPITAL FOR SICK CHILDREN, GLASGOW.—Dr. Finlayson has just completed a short course of demonstrations at this hospital of cases of Nervous Disease; there were illustrations of tumour of the brain and cerebellum, and a remarkable case of paralysis of the sixth and seventh nerves on *both* sides, with loss of sensibility of the palate, dribbling of saliva, affection of speech, &c., apparently due to a bulbar paralysis. These demonstrations were open to all medical students, and were arranged for the afternoon, as the ordinary visit hour did not seem very suitable for the summer arrangements of the students.

New Inventions.

A NEW OBSTETRIC BAG.

THE accompanying drawing represents a new obstetric bag which Messrs. Arnold and Sons, of West Smithfield, have kindly executed in accordance with my suggestions. Its general construction is as follows.

It is made of a light wooden case covered with morocco. It opens half-way down the centre, each upper half or wing falling outwards on a strong hinge, and having its fall limited to a right angle by two strong quadrants. To prevent the drawing from giving an impression to the contrary, I should mention that the wings will open outwards simultaneously, and not only one at a time as represented. The cavities of the wings are closed by strong leather lids, which are fastened with turn-buttons, and marked respectively A and B. Wing A contains long forceps, catheter, porcupine quill, hypodermic syringe in wooden case with ergotine, pilocarpine and morphia discs. Wing B contains perforator, craniotomy forceps, blunt hook, crotchet, and vectis. The main cavity of the bag, or well, is divided by a vertical partition into two compartments: the one being occupied by two cases of bottles (two four-ounce and four two-ounce); the other by a Higginson's syringe with long tube, a set of Barnes's bags, and a pocket-case in which are blunt and sharp bistouries, dressing forceps, needle-holder, needles, silk, and wire. This latter part of the well is covered in by a flat leather case containing an Aveling's transfusion apparatus, with special forceps and scalpel.



The advantages that this bag, in my opinion, possesses over others now before the profession are—1. Greater durability, owing to its general construction. 2. Avoidance of unnecessary exposure of instruments. On opening the bag no apparatus is visible. 3. Greater convenience, since the different sets of instruments are as far as possible packed together in separate cases or departments according to their functions. 4. Greater safety of the instruments themselves, because (*a*) the indiarubber is carefully separated from the steel; and (*b*), owing to the separate packing of the instruments, some of them need never be disturbed for years, thus escaping the daily dangers of injury to which they are usually exposed.

T. W. THOMPSON, M.R.C.S.,
Late Surgeon, 1st Life Guards.

SANITATION IN CALCUTTA.

AN important outcome of the recent differences between the Lieutenant-Governor of Bengal and the Municipal Corporation of Calcutta has been the formation of a Health Society for Calcutta and its suburbs. The inquiries instituted by the corporation and by the committee appointed by Sir Rivers Thompson brought prominently to public notice the very unsatisfactory state of certain portions of the city and its suburbs, and the resulting high rate of mortality. While in some of the wards in which the water-supply is good and the conservancy efficient, the death-rate has been as low as 12 and 14 per 1000; in other parts, where these conditions have been neglected, it has been 35, and in the still more unfavourably circumstanced suburbs has ranged from 50 to 60, per 1000. With a view to instruct public opinion upon subjects connected with health, the causes of the high rates of sickness and mortality due to preventable disease, and the most efficient measures for their removal, the Public Health Society has been formed. It is proposed to effect this very desirable object by means of lectures on subjects connected with hygiene, by public meetings for the discussion of sanitary questions, by the publication of a journal of health in which the most recent information on all matters bearing upon the subject may be given, and by the formation of a library of works on sanitation. It is the earnest desire of the founders of the Society to bring together by means of it "a body of influential persons representing every class in the community, European and native, who may by sustained effort and combined action, both form and strengthen an intelligent public opinion, and give expression to that opinion in a manner calculated to command attention, and who may thus co-operate with and aid Government and the Municipality in initiating and carrying out sanitary improvements." But the Society propose to introduce a further very important practical measure. The Council "have made arrangements for enabling such householders as desire it to have their premises inspected and a report drawn up, by a capable and properly trained officer, on any sanitary improvements necessary to render them healthy and safe. A competent overseer has been engaged for this purpose, and the charge for inspection and report have been fixed so low as to bring this valuable safeguard within the reach of all classes." The first public meeting of the Society was held on Jan. 29th, in the Imperial Museum, when the chair was taken by Sir Rivers Thompson, the Lieutenant-Governor. A paper was read by Surgeon-Major R. Harvey, of the India Medical Service, on "The Plague, a History and a Lesson," in which he gave an interesting account of the disease from the earliest periods to the present times. He concluded by a warning of the possibility of the plague again finding its way to Calcutta, and of the "congenial soil" which it would there find in the filthiness and unwholesomeness of parts of the city and its suburbs. "Even if we had no fear of plague—and I do not think there is much,—we have our own pet pestilence, cholera, which, though not contagious like plague, is fostered by the same conditions; and we must remember that all zymotic diseases obey in various ways the same laws." We regret that Surgeon-Major Harvey did not take up the subject of the prevention of these existing causes of mortality rather than the history of bygone pestilences, but we have no doubt they will form the subject of future lectures. We look upon the formation of this Society and the manner in which it has begun its work with great satisfaction, and we trust that it may do good and efficient work in the promotion of such measures as will improve the health and diminish the death-rate not only of Calcutta and its suburbs, but of the population of the towns and villages throughout the Presidency.

BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.—The sixty-third annual general meeting of this Society was held on May 29th. Mr. Sampson Gamgee, President, was in the chair, and there was a large attendance of members. The annual report stated that the work of the past year had been satisfactory in regard to the activity, prosperity, and usefulness of the Society. The invested funds at the end of 1884 amounted to £10,705, as compared with £10,515 at the end of the previous year. During the year fifteen annuitants had received grants, varying in annual value from £10 to £40. The number of benefit members is [illegible]. The financial statement showed that the total receipts during the year amounted to £[illegible] 8s. 11*d*. The following elections were made:—President: Mr. C. A. Newnham of Wolverhampton. President-elect: Dr. James Johnston of Birmingham. Vice-Presidents: Mr. Henry May and Mr. R. W. Smith. Drs. Foster and Wade of Birmingham, and Dr. Tibbitts of Warwick, were elected on the Directorate. Treasurers: Mr. Bartleet and Dr. Sawyer. Hon. Secretary: Dr. Thomas Savage. The members afterwards dined together at the Grand Hotel, under the chairmanship of Mr. Newnham.

THE LANCET.

LONDON: SATURDAY, JUNE 6, 1885.

SIR HENRY ACLAND, in his opening address at the recent meeting of the Medical Council, intimated that Inspectors appointed to visit the Final Examinations of the Universities have begun their labours, and would be supplied with all the information necessary for them to undertake their task. There ought to be a great deal of mutual respect between the universities and the Medical Council. The latter body contains eight representatives of universities. All the English universities but one have a separate representative in the Medical Council. The two Irish universities have each a representative; and the Scottish universities are represented, though only imperfectly—that is to say, the universities are grouped for the purpose of representation in the Medical Council; Edinburgh and Aberdeen alternately elect the representative, and Glasgow and St. Andrews. The Scottish universities might reasonably complain of this inequality of treatment; but the English and the Irish universities must admit that they have an amount of representation on the Medical Council fully equivalent to anything they do for the profession of medicine, or can reasonably claim from it or from a body regulating it. Not only is each of the universities of England, with one exception, represented by a separate member, but the President of the Medical Council is Sir HENRY ACLAND, who is identified conspicuously and worthily with the oldest of England's universities. Under these circumstances, in matters of medical education the universities might fairly be expected to defer greatly to the Medical Council, and the latter might fairly be expected to regard the medical regulations and the examinations of the universities with much attention and, if necessary, with a little candid criticism. We are not here defending the constant interference of the Council in regard to matters of general and preliminary education, which it has been trying for years to throw upon the universities and other bodies responsible for national education. We are referring to the strictly medical functions of the universities, and we maintain that in regard to these the Medical Council has its duties of supervision and even of criticism, which the universities ought to recognise and respect. That this is so is apparent from the Medical Act. The eighteenth clause of this Act provides that the Council may require of the bodies mentioned in Schedule A information as to the courses of study and other requisites for obtaining their qualifications. It also provides that members of the Council, or persons deputed by the Council, may attend the examinations of the bodies in Schedule A, making no distinction between universities and medical colleges or corporations. Clause 20 entitles the Council to make representations of defects in the requirements of the bodies to the Privy Council. Of course in a general sense, the right, and indeed the duty, of the Medical Council to take notice of the medical work of the universities is admitted. But it has not been thought to extend further than to see that the universities did not give their qualifications to persons not possessed of the requisite skill and knowledge for the efficient practice of their profession. This is surely not enough; and one of our principal purposes in referring to the commencing work of the Inspectors of the medical examinations of universities is to express the hope that we shall have from these gentlemen a critical and impartial estimate of the value of these examinations—not only as qualifying examinations, but as university examinations. The profession and the public look to universities to carry their examinations and tests decidedly higher than the standard of the mere pass examinations. It is the interest of the universities that this expectation of the public and the profession shall not be disappointed. Medical degrees are given very freely nowadays by certain universities. The University of Oxford even proposes to relieve itself of the duty of examining in Surgery by accepting the examinations for the diploma of the College of Surgeons. These things may be all right; but we want the Medical Council to assure us that they are all right, and that the higher titles of universities really mean higher examinations. The universities that are conscious of higher work will not object to have it testified by the inspectors of the Medical Council. Universities which give those "higher titles," of which Sir HENRY ACLAND lately spoke, which "are of no value at all"—if there are such universities—should be exposed. The sanctity of medical degrees must be recognised; but only so long as they represent what they profess to represent. We shall look for the record of the work of the inspectors of universities with much interest.

◆

THE Committee appointed by the Clinical Society about two years ago for the investigation of the results of Dr. MORTON'S Treatment of Spina Bifida by Injection of a Solution of Iodine in Glycerine, has at last made its report. Owing to its length, it has been read and published only in abstract, and we shall have to wait till the autumn for the full text, which will appear in the next volume of the Society's Transactions. The Committee wisely took a broad view of their task, and set themselves first of all to inquire into the pathological conditions grouped under the term "spina bifida." They have been able to divide them into three classes—meningoceles, myelo-meningoceles, and syringo-meningoceles. Judging from specimens preserved in the museums of London, Glasgow, and Cambridge, myelo-meningocele is the most common condition, and syringo-meningocele the rarest. But in view of the known great frequency of this deformity, and the comparatively small number of specimens in museums, it is open to question how far these collections fairly represent the actual proportionate frequency of these three varieties.

In the pathology of the affection the Committee have been able to settle definitely one or two points which are of considerable importance. First, they have proved by microscopical preparations that the vertical fissure does not involve the spinal cord, for the central canal of the cord can be demonstrated intact in the expanded nervous tissue. Secondly, they have shown that in myelo-meningoceles the spinal cord is flattened out and blended with the sac of the tumour in its median vertical portion, and that the nerves crossing the cavity of the tumour come off from the expanded cord in the usual way, and are not distributed to the sac, as has been erroneously stated. Thirdly, they have found that there is an absence of mesoblastic tissue in the walls of the tumours, in some cases partial, in others entire, and they regard the deformity as due to a want of development of this embryonic layer.

On the clinical side, the inquiry has extended beyond the investigation of cases submitted to Dr. MORTON'S treatment. A large number of cases of all kinds have been collected and tabulated, and these afford means for comparing the results of different kinds of treatment. The most surprising outcome of this part of the inquiry is the success that has often attended severe operations such as ligature or excision of the tumour, measures which have been adopted without an adequate estimate of the nature of the deformity and of the risk of the procedure. The Committee believe that the published records of these measures may be misleading, owing to the cases of failure not being recorded. To some extent no doubt this is true, but it is of course open to question to what extent this applies to such operations as excision more than to injection into the sac. But a still more important consideration is that in the cases thus treated paralysis has not been caused, as would be the result were the spinal cord removed, and in many cases it is expressly stated that the cord or nerves were not in the sac. This not only proves that these cases were examples of meningocele, but their number shows that meningocele is more common than museum specimens indicate. It is another demonstration of the fact that pathology must be studied in a wider field than our existing museums afford. The Committee, however, lay stress upon the fact that it is impossible in any given case to predicate the freedom of a tumour from spinal cord and nerves; in other words, they say that it is impossible to diagnose meningocele from myelo-meningocele. In many cases the surgeon may be certain the cord is in the sac; in other cases, where the tumour is pedunculated, covered by a thick healthy skin, and there are no concomitant nervous phenomena, it may be suspected that the cord is not in the sac, but it is impossible to be sure of this. If this statement be accepted, it follows of course that the surgeon must always act as if the cord were in the sac, as if he were dealing with a myelo-meningocele; and an instant's consideration will show that for this reason ligature or excision of the tumour, or indeed any operation which threatens the integrity of the median vertical portion of the tumour, must be entirely abandoned, and this in spite of the success that has often followed these measures. No doubt those who have practised excision successfully will be inclined to contest this point, and to doubt the impossibility of diagnosing meningocele; in view of the careful investigation and report of this Committee however, we doubt whether such operations can be justified. Turning now to the other side of this part of the report, we learn that the Committee have found that Dr. MORTON'S treatment has been attended with a large measure of success, and it is recommended as the best treatment at present known for this condition. The Committee advise that a careful selection of cases suitable for it should be made, and they urge that it is foolish to practise it where from the presence of grave marasmus or a marked condition of hydrocephalus, even the cure of the spina bifida would not offer a chance of materially benefiting the patient. The treatment is so simple, and, when properly conducted, so free from dangers of its own, that there is a risk of its adoption in cases quite unsuitable for any kind of treatment, with a view, perhaps, of giving the child a chance. Such a course, however, can only bring a valuable measure into unmerited ill repute, and it is to be distinctly deprecated. As to the mode of action of the iodo-glycerine, the abstract report furnishes no information; it contains, however, a clause to the effect that, with one exception, there is no evidence of the cure of spina bifida by this method ever having caused paralysis, and a doubt is expressed whether the subsequent occurrence of hydrocephalus can be fairly attributed to the previous cure of the spinal deformity. Congenital deformities are all extremely important, and no aid that surgery can afford is more welcomed than in their removal or cure. Spina bifida affords no exception; it is common, and is generally attended with early death, and up to the present its treatment has been to a large degree empirical and unsatisfactory. We anxiously await the publication of the full report of this Committee of the Clinical Society, because we think the abstract of it justifies the hope that it does much both to clear up doubts as to the nature of the deformity, and to put its treatment upon a more satisfactory, because scientific, basis.

◆

WHATEVER opinions may be held as to the value of the Report of the Royal Commission on the Housing of the Working Classes, there is no doubt that the printed minutes of evidence will be read by all with the deepest feelings of interest. There has been no lack of effort to obtain information on every point bearing upon the subject of house accommodation for the poor, and upon the relation of this accommodation to their social and moral welfare. Philanthropists, statesmen, clergymen, lawyers, architects, and officers to local authorities and building societies, have been examined, and each has added to the general stock of information which the issue of the volume now makes available for public use. When witnesses have been so numerous, it is not surprising to find that opinions widely apart have been expressed. Thus we find, on the one hand, a demand for fuller legal powers and better rights of inspection; and on the other, the strongest objection taken to State interference of any kind whatever. Again, while some witnesses demand the use of public moneys for the erection of suitable dwellings, others protest against this course as demoralising and dangerous. It is, however, easy to reconcile these apparently different opinions when the experience of the individual witnesses is taken into account. We can sympathise with those landlords upon whose tenants the sanitary inspector may be an unnecessary intruder, but we cannot yield to the opinion that he is not the less urgently required when house owners neglect their duty to their tenants and fail to keep dwelling-houses in habitable condition. The evidence, indeed, points more clearly than the report to the one conclusion that the enforcement of sanitary law and the efforts of the philanthropist must go hand in hand if the condition of the working classes in our large towns is to be benefited. Perhaps no evidence will be read with greater interest than that of Lord SHAFTESBURY, who, speaking with the experience of two generations, is able to bear witness to the enormous improvement which has taken place during this period. Lord SHAFTESBURY has seen a far worse condition of things than that which is now the cause of so much condemnation, and we are at liberty to assume that this has resulted in no small degree from the operation of the Sanitary Acts. The chief problem to be solved, however, is whether suitable dwelling-house accommodation can be provided in sufficient quantity and at a rental which will not unduly tax the weekly earnings of working people, and the evidence of those who have been engaged in making such provision as they could, forms one of the most valuable portions of the volume. London is already learning how this may be done, and it is now being found that it is possible to erect, as a mere pecuniary speculation, tenemented houses of the model kind for artisans; whereas, a few years ago it was thought that such dwellings could only exist as the result of individual benevolence. The formation of companies is doing much, not only in providing dwellings, but in setting an example which builders are slowly following. A few years ago it would have been thought very difficult to find tenants for buildings of the model type, but the rapidity with which those that have been erected have been occupied has proved the contrary. At the present time it is urged that the labouring classes would be unwilling to live under any other conditions than those to which they have been accustomed; but this, too, will be found to be fallacious as soon as suitable accommodation of this class shall have been provided. It will not be long before such buildings have been erected by a company which has been formed for this purpose, and as soon as its success has been proved, it may be anticipated that builders and others will again follow the example that has been set them. But the very moment the State steps in, and at the cost of the community erects dwellings for a class, individual effort will be retarded and great injury done.

Much evidence has been taken on the subject of one-room tenements. It cannot be denied that single rooms will be required by some, and there can be no objection to their use on the score of morality so long as due regard is had for the age and sex of the occupants. The action of local authorities in providing isolation hospitals, baths, and washhouses, as well as mortuary accommodation, is intimately associated with this question. Hope is raised by a perusal of the evidence that such rooms may be supplied at a cost which the labourer will be able to bear. The problem is not altogether solved, but certainly more nearly approaches solution than in past times. A continuance of the improvement in the dwellings of the working classes cannot be accomplished by any one person or any one body, but will be the result of all the forces which have been steadily working for years, and which will doubtless gather fresh strength as the result of the recent inquiry.

AN active correspondence in the Birmingham *Daily Post* amply proves that the management of the local Medical School is just now exposed to much adverse criticism. The evidence at hand is not sufficient to form the basis of an impartial judgment on the questions raised; but it establishes a strong *primâ facie* case for inquiry into the causes of the existing dissatisfaction, and the best manner of remedying it. It is only just to recall that the traditions of the Birmingham Medical School are most honourable and encouraging. Even before the days when Sir WILLIAM BOWMAN was a dresser in the Birmingham General Hospital, under Mr. JOSEPH HODGSON, the local physicians and surgeons had done excellent work. From their ranks have since sprung leaders in almost all departments of medicine and surgery. When the medical examining bodies published their statistical results, the Birmingham School took an honourable place, and held it. The present class of students is a numerous, enthusiastic, and well-conducted body of gentlemen, fully entitled to all that can be done for their higher education. But, unfortunately, the School is so split up into sections that it is not easy to determine who is responsible for any deficiencies that may exist, or to whom to appeal to remedy them. The General and Queen's Hospitals, forming jointly one of the richest clinical fields in the kingdom, are amalgamated for purposes of clinical instruction, their acting honorary officers constituting a clinical board, which appropriates the whole of the clinical fees for its members, and is virtually autocratic. The lectures on botany, chemistry, physics and physiology are given at the Mason's Science College. This is a new institution of very high promise, just now presided over by a distinguished physician, who has munificently presented it with a library of twelve thousand volumes, but not otherwise under the influence of the medical profession. At the Queen's College, which is the parent medical school, the other lectures are given; and there the professors are practically the governing body. It has been their custom, for some years, to reconcile rival claims by appointing two professors to several of the chairs; while some subjects, notably pathology and a few of the leading specialties, appear to have received scant attention. It can scarcely be doubted, that if the Councils of the Queen's and Mason's Colleges and the Clinical Board of the amalgamated hospitals, recognising the solidarity of their own and the students' interests, appointed a representative committee of inquiry, the first step would be taken towards solving the existing difficulties. The authorities of the town and the governors of its hospitals, the medical practitioners and students, have obviously a strong and common interest in the honour and prosperity of the Birmingham Medical School. The materials for organising it are at heir doors. Vested and personal interests may fairly claim equitable consideration; but, if they block the way, they will have to yield to the common and major good.

WE yield to none in sympathy with our brethren of the Poor-law medical service, or in desire to assert their right to a measure of justice which has for many years past been denied to them. At the same time it is necessary to be strictly accurate and politic in the statement of their grievances. We sometimes fear that the avowed champions of their cause are not so careful in these respects as it were well they should be. For example, in reference to the burning question of medical relief and disqualification, which has just now been fanned into a flame by factitious processes, it is abundantly evident that there is much to be said on both sides of an issue hastily raised, and made by *ad captandum* processes of reasoning to appear in a light wholly unnatural to it. The facts are simply these. All are agreed that medical officers appointed for the relief of the poor ought not to be expected to attend persons who are not absolutely indigent. It is a scandal that the most over-worked and worst-paid class of public officials should be taxed in time and strength for the convenience of men who, with their wives and families, are able to earn a fair wage; and it is only just that those who take advantage of the public rates by availing themselves of the services of the Poor-law medical officer should in virtue of a recourse to such relief be deemed to be pauperised, and consequently lose their citizen privilege of the franchise. If some such check as this were not imposed on the unthrifty classes, there would be an indiscriminate abuse of the gratuitous medical advice and assistance provided at the public expense. There can be no sort of question on the score of right and expediency thus far. The point at which difficulty arises is that at which it becomes necessary to define "medical relief" in such a way that, while abuses are prevented, no obstruction shall be thrown in the way of prompt assistance in all cases of severe illness, particularly of the class which it is especially important to the community at large to stamp out. We must not encourage concealment of disease or delay in seeking assistance on the score of a wish to retain electoral privileges. It ought not to be forgotten that the extension of the household franchise to the counties involves the inclusion of an immense class of agricultural labourers in the number of those who vote. These persons are barely able to keep body and soul together on the pittance they earn. Unless an entirely new and well organised system of provident societies can be established, there is not the slightest chance of the majority of these electors avoiding the parish doctor. They form the bulk of his poor patients now; they must do so in the future. If their number can be reduced by the fear of losing the privilege about to be conferred on them, we shall be heartily glad; but it must be distinctly understood that the question is not one of keeping a new class away from the doors of the medical officer, but of getting rid of some at least of his present *clientèle*. There will be no increase of the heavy burden of work that presses on the district medical officer; the only question is whether by any manœuvre his toil can be lessened. This seems to be forgotten or put out of sight by too many of the disputants in this controversy. Moreover, as the Poor-law authority is the sanitary authority in many rural districts, unless the hospitals for infectious diseases are put on a separate footing, the labourer will be disfranchised for allowing his child to be isolated. This must be avoided. The shortest way out of the difficulty would probably be to pass a short Act of Parliament defining "medical relief" on a fair and equitable basis. With this arrangement everybody would be satisfied, and both the public and the profession would be content.

THE death is announced of Dr. W. L. Crowther, of Hobart. He became a Member of the Royal College of Surgeons of England in 1841, and was elected a Fellow in 1874. He was one of the few recipients of the Gold Medal of the College, given for special services to the Museum. For many years he was Surgeon to the Hobart Hospital, but had lately devoted himself chiefly to politics. He was sixty-eight years of age, and the cause of death was peritonitis, from which he had been suffering for about a fortnight.

Annotations.

"Ne quid nimis."

THE GORDON MEMORIAL.

THE scheme originally proposed by Sir E. Inglefield, and provisionally accepted by H.R.H. the Prince of Wales and the members of the Gordon Memorial Committee, to found and endow a hospital at Port Said, with the object of perpetuating the memory of the "dauntless Christian hero of Khartoum," has been given up in consequence of the unfavourable reports which have been received concerning it. Two Royal Engineer officers and an officer of the medical staff reported that the site proposed for the hospital at Port Said was in every respect unsuitable, and that its sanitary conditions were as bad as could possibly be imagined. The Committee, after a careful consideration of these reports, resolved that the proposal to erect a great hospital at Port Said as a national memorial to General Gordon must be abandoned. They do not appear to have been prepared to recommend anything else instead of their abandoned scheme but, on the motion of Cardinal Manning, seconded by Lord Napier of Magdala, it was resolved: "That the members of this Committee be invited to submit in writing any suggestions they may desire to make for the appropriation of the fund for the consideration of the subcommittee, together with the applications and suggestions already in the hands of the secretary, and that the subcommittee be requested to bring up their recommendations on the subject to this committee at their next meeting." The task thus devolved on the subcommittee is an important but difficult one, for we have no doubt they will have plenty of suggestions, possible and impossible. One advantage of the delay will be that time will be afforded to ascertain how far any scheme which may appear advisable to them is likely to be capable of practical application. Of the many proposals which have already been made, and will doubtless be brought before the subcommittee, there is none which strikes us as more in accordance with Gordon's character than that of an institution for the redemption of some of our waifs and strays by affording them a chance of being trained to means of earning an honest livelihood. The success which has attended some of those institutions which already exist for the homeless and destitute is certainly encouraging, but they are far too few in comparison with the numbers for whom they are required. The interest which Gordon took in this class may be accepted as an indication of the work which he would have been anxious to promote and which therefore would form an appropriate memorial of him. Some steps have been already taken in this direction, independently of the committee, with a view to establish what it is proposed to call the Gordon Boys' Camp. The amount at the disposal of the committee appears to be only about £17,000, but if some such scheme were taken up by the Prince of Wales and the committee of the fund, and were brought before the public in a practical and business-like manner, we have no doubt that money would be forthcoming to carry it out in a manner in every way worthy of the great and good man whose name it is proposed in this manner to perpetuate.

DEATHS FROM CHLOROFORM.

AN inquest was held at Guy's Hospital on May 27th, on the body of a man, aged twenty-four, who died from the effects of chloroform, which was being administered for the purpose of aiding in the reduction of a dislocated humerus. The post-mortem examination revealed nothing more than "slight disease of the large vessels of the heart." In fact, the medical evidence was to the effect that there was no organic disease sufficient to account for death. There seems no reason to doubt that the deceased succumbed to the toxic action of chloroform, promoted, it may be, by a certain amount of shock incidental to the operation. On the 31st ult. Dr. Danford Thomas conducted an inquiry into the circumstances connected with the death of Rebecca Townsend, aged fifty-three, which happened at the Middlesex Hospital whilst the deceased was being anæsthetised, with a view to abdominal section. The heart was examined previously, and found to be "quite sound," but the autopsy revealed "enlargement of the heart and liver, and disease of the other organs." Such cases illustrate well the dangers to be apprehended from chloroform narcosis. In the former of the two it may be said, however, that there was nothing to lead to the supposition that the danger would not in all probability be escaped, for the patient was young and free from visceral complications. The latter case was instructive, inasmuch as it showed that, in spite of careful examination immediately before the induction of anæsthesia, grave structural alteration of the cardiac tissue may pass undetected. It may be fairly assumed that when a patient has reached the age of fifty years the integrity of the vascular system is more or less undermined, and experience teaches that the extent of the lesion may be out of all proportion to the physical signs. Age, then, is always an important factor in estimating the propriety of chloroformisation. The rule generally laid down is that if the operation is severe and likely to be followed by dangerous shock, it is proper to give an anæsthetic if the operation is justifiable. The latter question fortunately does not come within the province of a coroner's jury, who could never be allowed to discuss and adjudicate upon a purely technical matter. For that reason it behoves every surgeon to weigh carefully the evidence in favour of and against the patient being anæsthetised, and also to select the anæsthetic least dangerous to life, which is sufficient for the purpose of his operative procedure. It is a noteworthy fact that death from chloroform has occurred with somewhat unusual frequency when the drug has been inhaled prior to the reduction of a dislocation. There being as a rule no external wound complicating this accident, one is apt to under-estimate the amount of shock produced by the violence, which must really be considerable, and continued so long as the dislocated bone keeps the trunk nerves on the stretch. Again, there is always an uncertain quantity in the "personal equation," which experience alone can give a clue to; and unfortunately this is not always available. In the former case, related above, there is sufficient evidence to show that the "personal equation" was highly developed; or, in other words, that the deceased was peculiarly susceptible to the action of the poison on the cardiac nervo-muscular dynamism.

VACCINATION AND SMALL-POX.

IT is not a little remarkable that while anti-vaccinationists are constantly accusing the supporters of vaccination of disingenuousness in dealing with vaccination statistics, it is scarcely possible to find any contribution from the opponents of vaccination that is not obviously open to similar charges. Fallacious statements are made in the interest of anti-vaccination which, even if met by the most unanswerable rejoinders, are never withdrawn or even modified. Mr. Charles H. Hopwood, Q.C., who is at any rate a consistent opponent of vaccination, recently published a letter in the *Standard* which contained, among other assertions, the following paragraph:—"May I add that the figures from the Registrar-General's returns show that, taking all ages above two years, the death-rate of the vaccinated is 13·76, and of the unvaccinated 13·15?" Here is a statement made by an M.P., on the asserted authority of the Registrar-General's returns, showing that the mortality of the unvaccinated from small-pox is rather less than that of the vaccinated! This statement, with its authority, will doubtless be printed and disseminated widely by the agents of the Anti-vaccination Society. It is needless in these columns to dwell upon the fact that such a statement is not only false in substance, but that it has no shadow of support in any returns of the Registrar-General, which tell a very different tale. A correspondent in the *Standard* has since pointed out that the Registrar-General's returns show that the mortality among the unvaccinated in England and Wales from small-pox is twenty-nine times greater than that among the vaccinated. Another correspondent points out that the statement quoted by Mr. Hopwood, and said to be based upon the Registrar-General's returns, was taken from the translation of a passage from a German report, purporting to be based upon the experiences derived from a population of 60,000 officials and workmen employed on the Imperial Austrian State Railways. The translation from the German was by Mr. Hume-Rothery, the late President of the Anti-vaccination Society. Mr. Hopwood, it is true, has since acknowledged his error in giving the Registrar-General's returns as his authority for the statement that the mortality from small-pox is greater among the unvaccinated than among the vaccinated. He does not, however, even allude to the fact that the returns of the Registrar-General give results diametrically at variance with those quoted by him on the authority (as he says, preferred by him) of an unofficial German report containing the observations of one observer, who purports to have discovered that vaccinated persons suffer more severely than the unvaccinated, and revaccinated persons more than the vaccinated. The Registrar-General's figures, on the other hand, are based upon the combined observations of more than twenty thousand observers, and are thus comparatively free from the defect of possible individual partiality. Mr. Hopwood's claim of silent admission of other statements in his letter, many of which are mere assertions, is not worth discussing.

PHYSIOLOGY OF LACTIC ACID, CREATINE, UREA AND GLUCOSE.

IDIOPATHIC diseases probably owe their obscure nature largely to our want of knowledge of the intimate chemistry of the body. A complete knowledge of physiological chemistry would imply a perfect understanding of life in so far as we are capable of understanding anything. Hence the importance of all studies tending to elucidate this subject. In a pamphlet on the origin and formation of lactic acid, creatine, urea, and glucose in muscular tissue, Dr. Latham has attempted in an ingenious manner to throw some light on processes of metabolism. He attempts to show that albumen is a compound of cyan-alcohols united to a benzine nucleus—the cyan-alcohols are supposed by him to be derived from the various aldehydes, glycols, and ketones; that lactic acid may be obtained in two ways, either from $C_2H_4\left\{\begin{matrix}OH\\ON\end{matrix}\right.$ or from changes and condensation in $CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ from which latter molecule creatine and creatinine may also be derived; that urea may be obtained from one series of cyan-alcohols with the production of a cyan-alcohol higher in the series. We have not the space to follow Dr. Latham through the various formulæ by which he is led to the above conclusions. Whilst we feel strongly that his attempts are deserving of careful consideration, they can, however, only be regarded as tentative. A few years ago Dr. Latham showed how, by a combination of cyan-alcohols, bodies might be obtained having the same composition as that given by Schutzenberger for albumen. The chief objection to the formula which he then suggested was "that it consists of a large number of molecules in *molecular*, as distinguished from *atomic*, combination; and, on the whole, organic molecules seem to have extremely little tendency to enter into this kind of combination." Dr. Latham now submits a formula which, by combining the cyan-alcohols with a benzine nucleus, gives rise to a body having the same composition as albumen.

THE GRESHAM COLLEGE: AN ARREST OF DEVELOPMENT.

A LETTER published in a daily *contemporary* on the Gresham Lectures has directed timely attention to a public trust, the present usefulness of which its firmest supporters will hardly venture to extol. Gresham College was designed by its enlightened founder to be an "epitome of a university in London." It is not perhaps his fault that it has remained an epitome of the barest kind. He laid the foundation of a university by forming and endowing a nucleus or nuclei of instruction in each of the recognised departments of learning, and he left it to posterity to develop the structure. Had the bequest been made in our own time, it would probably have shared in the general advance in organisation which has aided the efforts of other teaching bodies. As events have proved, the Gresham lectureships, locked up and isolated by restrictions, and devoid of scholastic method, have been of little service either in training pupils or encouraging research. Like mummy wheat, they contain the germs of successful growth, but they have not sprung up for want of the needed contact with soil and moisture. Of late years various plans have been suggested by which their dormant life might be awakened to activity. Mr. Goschen's suggestion, that their endowments should be transferred to the University Extension Society, is one of these. Metropolitan teaching bodies have in their turn been proposed as the natural heirs of the same property. Should any one of these amendments be carried out, it is evident that alterations will have to be made in executing the expressed intentions of the founder. No injurious change need, we think, be introduced; and the original idea would be consistently maintained if the "epitome" of Sir Thomas Gresham could be developed into an efficient teaching university for the whole of London. The gratis attendance provided for by the terms of the bequest might be modified, in the case of the lectures specially mentioned in it, by the imposition of a nominal fee sufficient to ensure that only *bonâ-fide* students should attend them. The methods of instruction could be assimilated to those of other universities. Understanding the public spirit of our time and country and the zeal for education of the merchant companies, we do not despair that they will find means of moulding to full shape and use the too long embryonic form of this large and wise intention.

BELLADONNA POISONING.

ON Friday, May 29th, six boys, aged from six to nine years, were taken to St. Thomas's Hospital suffering from symptoms of poisoning by belladonna. Between 12 and 1 o'clock they were playing together with others, when a boy about fourteen accosted them and asked if they would like some "Spanish"; on their replying in the affirmative, he gave them some black fluid out of a bottle. All those who took any of it became ill, and when seen by Mr. Robinson, the house-physician, two hours later, presented very similar symptoms. Two were able to return home, their symptoms being of slight character; but four were admitted. One aged nine, who suffered most, presented a flushed excited appearance, his eyes being bright and pupils widely dilated; he refused to take anything; there appeared to be some loss of power in the legs: he had attacks of rigidity of the limbs, between which he tossed about. In the evening he complained of dry throat, double vision, had hallucinations, and frequent micturition. He was delirious up to 4 o'clock the next morning, when there was still dryness of the throat, dilatation of the pupils, and an erythematous rash on the arms and legs. He gradually recovered, without intestinal symptoms. Each boy was given an emetic of sulphate of zinc, after the action of which the stomach was washed out with warm water. A quarter of a grain of morphia was injected subcutaneously, and the sleepy condition induced was counteracted by forced exercise. In the two most severe cases coffee was given per rectum. It was not possible to ascertain the exact character of the fluid taken, but a piece of broken bottle was found which was stated to have been part of that from which the fluid had been given, and to this some sticky sweet-smelling material was adhering. It was not, however, taken to the hospital for examination. The boy who "treated" the others was not again seen, and there was no clue as to the possession of the poison; but from the frequency with which belladonna is prescribed for inflammatory conditions in our out-patient departments, it is not improbable that it was obtained from one of the large hospitals.

SMALL-POX AT THE EAST-END.

AT the meeting of the West Ham Board of Guardians on the 28th ult., the report by Dr. Moir, medical officer of the Small-pox Hospital, on the second series of 1000 cases of small-pox treated in the Board's Hospital at Plaistow was read. His previous report was made in February, 1882. The epidemic had been more severe and protracted than that of 1881, but the house-to-house visitation instituted by the guardians had already been of the greatest service in increasing the number of vaccinations and revaccinations, and would, in his opinion, prevent the spread of the disease in the future to such an alarming extent as it had assumed in the past through the neglect of those simple and efficient precautions. In all the 2112 cases treated in the hospital, no death from small-pox had occurred after revaccination. At the same meeting, Dr. Kennedy submitted a report on the house-to-house visitation which had been carried on under his supervision in the parishes of West Ham, East Ham, and Little Ilford. The visitation extended from March 30th until May 14th, and during that time 25,257 houses were visited, and the statistics of 142,220 persons were obtained. Of the above persons, 140,186 were found to have been vaccinated, or 98·6 per cent. of the whole; 25,102, or 17·6 per cent., were found to have been revaccinated; 2034, or 1·4 per cent., were found to be unvaccinated. Out of 140,186 who had been vaccinated, 6232, or 4·4 per cent., had had small-pox at some time during their lifetime; and out of 25,102 who had been revaccinated, only 25, or ·10 per cent., had had small-pox at some time during their lifetime.

GASTRIC DILATATION.

A CASE of excessive dilatation of the stomach is mentioned in the *Vrach*, which occurred in the clinic of Professor Koshlakov of St. Petersburg. The patient was a peasant aged forty, and had been ill for three years. It was found that six litres of water could be introduced into the stomach without occasioning the man any inconvenience. The same journal records the case, by L. Scheffer, of a peasant, aged forty-nine, with intestinal obstruction, who, after the stomach had been twice washed out, passed a stool containing ascarides. Two grains of santonin were then given, with jalap, and about twenty round worms, which had been the cause of the obstruction, were passed.

OBLITERATION OF ONE LUNG, WITH DISPLACEMENT OF THE HEART.

At the closing meeting of the Islington Medical Society, on the 26th ult., Dr. Glover gave the particulars and showed the specimens of two very striking lesions in the case of a man aged sixty-three, whom he had known for several years as a dispensary patient and otherwise. The most noticeable peculiarity was the complete displacement of the heart. It occupied the right side, and beat between the fourth and fifth ribs. This fact had been observed thirty-five years ago by Mr. Jackson, one of the oldest members of the Society, and the patient had been examined by many physicians, amongst others by Dr. Austin Flint, who came to the conclusion that there was no transposition of organs—a conclusion verified by the post-mortem. But the autopsy revealed another lesion, which was as remarkable as the malposition of the heart. This was the almost complete absence of the right lung. It had to be long sought for ere it could be found, and was then discovered as a very hard shrivelled substance, in shape something like a sausage. On being cut into, it was found to consist almost entirely of thickened pleura, the pleura being at points half an inch thick. The lung substance was nearly destroyed, not with intersecting bands of fibrous tissue, but by this envelope of thick pleura. The left lung was correspondingly large. No history of pleurisy could be traced in the patient's life, and no history of consumption in that of his family. He had always been weak and slight. His mother always had noticed "a beating on the wrong side." He used to have severe bleedings at the nose. His chief troubles had been cough and rheumatism. He died in the Islington workhouse of broncho-pneumonia. It is common to say that a person has lost a lung, but here the statement was a literal expression of the fact, though the patient contrived to live without it, and with his heart on the wrong side, for sixty-three years.

DEATH CERTIFICATES.

Mr. J. C. Malcolm, Borough Coroner of Chapel Allerton, during the holding of an inquest recently, is reported to have delivered himself as follows: "It was not an uncommon thing in Leeds for some medical men to certify that deaths had arisen from natural causes where they had actually resulted from violence or accident." This may or may not be the case; but before we can join the coroner in his sweeping denunciation, we should like to know whether he believes that the certificates of the Leeds doctors are given with the knowledge that they are false, or even carelessly, without their taking the trouble to ascertain the truth of the facts "certified." The whole question turns on this. We yield to no one in advocating the advisability and insisting on the necessity of all death certificates being rendered in unambiguous language and with the strictest accuracy. Nothing is more detrimental to the cause of pathology and scientific medicine than that the proximate causes of death should be treated lightly, as though they were of no practical use.

THE TUBERCLE BACILLUS.

Dr. Fütterer gives the result of some examinations he has made of tuberculous organs with respect to the distribution of bacilli in them (Virchow's *Archiv*, Bd. 100, Hft. 2). In caseous broncho-pneumonia, several colonies of bacilli were met with in each of 200 specimens examined, and disposed mostly in an arborescent manner like the smallest bronchial divisions. The colonies covered areas as large as from three to five alveoli, and were most abundant where softening was in progress. In miliary tuberculosis with desquamative pneumonia, bacilli were found in thirteen out of sixty sections examined, in masses within the tubercles, and in one specimen within a thrombus in an artery. In miliary tubercle of the liver, they occurred around vessels, but not within them. In tubercle of the kidney, bacilli were found around and within bloodvessels, in a glomerulus, and once within fibrinous exudation in a convoluted tube. In no instance did he see bacilli within giant cells. He believes that the bacillus stains variously according to its stage of development, which may account for its being overlooked occasionally. Its preponderance in softening masses indicates that it is the cause of the softening process, which he compares with putrefaction, and this also explains the abundance of bacilli to be detected in the sputum.

THE PARKES MUSEUM.

The Council of the Museum have determined to hold during the summer months, when lectures are impracticable and unattractive, a series of annual exhibitions devoted to some limited subject having reference to hygiene. The first of these exhibitions is to be opened on Monday next, when will be displayed a complete series of the inventions of Mr. Fletcher of Warrington, for the domestic use of gas. Many of Mr. Fletcher's inventions are well and favourably known to the public, but at the forthcoming exhibitions several novelties will be on view, and all the typical exhibits will be shown in action. The articles will include gas cooking and heating stoves, instantaneous water heaters, washing and drying machines, grillers, hot plates, ranges, confectioners' ovens, coffee roasters, workshop tools, &c.; and a professed cook, Miss Young, will be in attendance to explain the apparatus, and to give, in addition, a formal lecture daily on the art of cooking by gas. There can be no doubt that the use of gas for domestic purposes has a very great future, and with regard to much of his apparatus, Mr. Fletcher is, we believe, able to demonstrate that it is economical, expeditious, and cleanly. The Council of the Parkes Museum, in inviting an individual inventor to display his inventions in their building may seem to be taking no little responsibility upon themselves; but it must be remembered that the space at their disposal is far too limited for anything like a complete gas exhibition, and they have, we think, judged rightly in furthering as a first experiment an adequate exposition of the inventions of one gentleman of acknowledged repute, rather than the inadequate display of the apparatus of many inventors. The exhibition will remain open for three weeks.

SOUTHBOROUGH WATERWORKS.

We are glad to learn that Southborough has at last obtained the priceless boon of a good supply of excellent drinking-water. The report of Dr. Frankland declares it to be of excellent quality for drinking, and being also very soft it is well adapted for washing. The local board of the town have had to overcome considerable difficulties, including opposition from a section of the ratepayers who dreaded the effects of costly works on the rates. Seeing, however, that Southborough, like its neighbour Tunbridge Wells, is growing more of a residential place and less of a seasonal resort year by year, it is certain that the local board have acted for the best interests in securing a pure water-supply. Owing to the nature of the geological formation, and the fact that many of the springs are ferruginous and therefore unsuitable for dietetic purposes, the quantity of water of a suitable nature in the neighbourhood is limited. The spring which the local board have secured diminished very considerably during the exceptional drought of last year, as was to be expected; but at its lowest would have supplied ten gallons a head per diem for all who are likely to use it for some few years to come, without the assistance of any stored water. As, however, the population of Southborough has trebled almost within the space of a single generation, the question of storing the surplus of the rainy season for the wants of the dry season must soon arise. The opening ceremony was performed by Mr. Deacon, who, as lord of the manor, had granted a portion of the common on which to erect the pumping station. The day was observed as a general holiday, the tradesmen closing their shops at midday and a treat being given to the school children, while the local board and several of the gentry and tradespeople of the town met at a public luncheon.

XANTHELASMA.

THE histogeny and histology of xanthoma or xanthelasma have received fresh consideration at the hands of Dr. Karl Touton of Wiesbaden, who has published a long essay in the *Vierteljahresschrift für Dermatologie und Syphilis.* He regards xanthoma as a tumour in the narrow sense of the word. It is a sharply defined, independent new growth, composed of elements which do not normally exist in the part in which it grows—that is, the cutis vera. Xanthomata may be mixed tumours. Touton would speak of fibro-xanthoma, sarco-xanthoma, cystadeno-xanthoma, and myo-xanthoma. The cells of which the xanthoma is composed are described as having a sharply-defined membrane, with finely granular or faintly fibrillated contents and large round or oval nuclei. These characters are obscured by the presence of large globules of fat. The fatty infiltration is believed to commence as soon as the development of the cells themselves—a belief which is said to be strengthened by an *observation of* Colin, to the effect that in the majority of cases the small flecks of xanthelasma have a citron-yellow colour, even when they first appear. The article to which we refer contains an excellent account of the literature of the subject.

CORONERS' INQUESTS AND MEDICAL EVIDENCE

ON May 27th an inquest was held at the Royal Hotel, Worksop, before Dr. Housley, district coroner, touching the death of a man aged sixty-four years, who died without having had recent medical assistance. The case is of interest on account of the extraordinary course taken by the coroner, who is stated to have refused to allow the medical man who was called in to see the body a fee for his evidence on the grounds that he (the coroner) "only requested the evidence of the doctor as a common witness." We earnestly hope that our informant—the *Retford News*—has misreported the actual occurrence, for we can scarcely believe that a medical coroner would take such high-handed proceedings. On the *assumption* that the report before us is a true one, we should like to ask Dr. Housley whether he considers it such an easy matter in all cases to say whether life has actually ceased or not. If it has *not*, the body is not within the jurisdiction of the coroner. When scientific men have laboured, without success, *for centuries* to discover an infallible sign of death which shall at *all periods* be within reach of the observer, surely the question requires some one other than "a common witness" to determine it.

THE BRITISH MEDICAL ASSOCIATION.

THE fifty-third annual meeting of the British Medical Association will be held at Cardiff on Tuesday, July 28th, and following three days. An address on Therapeutics will be delivered by Dr. W. Roberts, Consulting Physician to the Manchester Royal Infirmary; an address in Surgery by Mr. John Marshall, Professor of Surgery in University College; and an address in Public Medicine by Mr. T. Jones Dyke, Medical Officer of Health for Merthyr Tydvil rural and urban sanitary districts.

THE TREATMENT OF FEVER AS A SYMPTOM.

WHILE the chief object of all medical treatment is necessarily to eradicate disease by attacking its very beginnings, there are times in which the relief of a pressing symptom may constitute the first important step towards recovery. Fever is such a symptom. How often does one find that, even in the presence of an active morbid cause, the mere remission of temperature for a certain period assists the physician, by obtaining rest for his patient, by gaining time, by quieting irritability in the neighbourhood of a source of mischief, and so converting an acute into a subacute or chronic process. These effects appear in many diseases which are said to run an unvarying course—in typhoid fever and early tuberculosis, for example; and there are good physiological reasons why the abatement of fever in itself should materially aid and tide over other efforts of nature or of art which are designed to cut the root of unhealthy action. It becomes, therefore, a matter of interest to inquire in what way a fall of temperature can thus react upon the local processes which determine the course of fever, and that fever does depend on local causes may probably be accepted as an axiom. All its features tend to show that it is a nervous disorder which acts along the lines of the vaso-motor system, that its method is reflex, and its result a destructive metabolism, which reveals itself in general emaciation, and is most intense at the original seats of morbid irritation. The aim of antipyretic measures must therefore be to allay this nervous overwork by opposing a buffer to the repeated shocks of peripheral stimuli, and this may clearly be accomplished in more ways than one. Thus it is frequently possible, by using narcotics, to lull the excited cerebro-spinal centres generally, and so to weaken their response to provocation. By another agency the constricting influence of the vaso-motor centre may be specially and directly inhibited and the circulatory system proportionally eased, as would seem to be the case when salicylates are employed. In this case, also, the harassed nervous centres share the general rest. The heat-regulating mechanism, too, if it exist as a separate factor, may be restrained by similar means, when its disordered forces would otherwise result in riotous excess of tissue change. In any case, the reduction of fever, besides preventing general loss of power and substance by wasteful molecular action, is directly beneficial in another way. By depleting areas which border on the causal irritant or its habitat, and the intense congestion of which magnifies the force of stimulation, it must react as a sedative at the very source of disease. These observations suffice to show why antipyretics possess a real value even in such diseases as continuous fevers. Apart from the aid they render to the further resources of medical skill, and apart from their action on septic germs, they often appear, by the rest which they procure alone, to constitute the chief element in the cure of febrile disease.

COUNTY COURT MEDICAL ACTION AT BATH.

THE *Bath Herald* of May 23rd gives a full report of an action by Mr. Algernon Sudlow of Castle Combe for the recovery of a small bill for medical and surgical services to the family of Mr. Henry Taylor. The chief services were setting a collar-bone and attending the case, for which 21s. was charged, and eight visits to a case of diphtheria, for which the sum of £1 16s. 6d. was charged. In the latter case Mr. Sudlow was summoned at night and found the child *in extremis.* He tried to detach some membrane from the throat with a brush dipped in a lotion, when the child convulsively closed the jaws and the brush was detached from the handle. It was soon removed from the mouth, but the child was found to be dead. The objection to pay the moderate medical bill was founded on this latter incident, which was of course to be regretted, but was in no way the fault of the medical attendant. We are sorry to see that Mr. Hooper of Ford, surgeon, gave evidence for the defence and questioned the diagnosis and treatment. He would not have used the brush because he thought the case hopeless. The judge made short work of this medical argument, and entirely vindicated the doctor's treatment and charges in what he properly called a battle between skill and death. It is always a pity when patients in an ungenerous spirit seek to evade payment of medical bills. We notice the case with satisfaction as one more instance of the usefulness of the county court in upholding the just claims of an underpaid profession.

CHOLERA IN SPAIN.

THE Spanish Government, which last week interdicted Dr. Ferrán from continuing his "cholera vaccination" pending further inquiry, has lost no time in appointing a Royal Commission for the latter purpose. The Commission commenced proceedings at Valencia on the 29th ult., and obtained evidence concerning the existence of suspicious cases of cholera in the district since the end of March, the number having greatly increased during the past fortnight. Dr. Ferrán was authorised to repeat his inoculations in places visited by the Commission; but it may be doubted if the members are sufficiently acquainted with microbiology to be competent to pronounce an authoritative opinion. Later advices state that the Commission has already reported that cholera prevails, and that the authorities are taking measures to limit the spread of the malady.

TOLERANCE OF MORPHIA IN PERITONITIS.

AT a meeting of the Cincinnati Medical Society in April Dr. Eichberg reported a case of perityphlitis and peritonitis in which during six weeks 340 grains of sulphate of morphia were given and for twelve days of this time as much as half a grain every hour or twelve grains per diem. The patient recovered. Another feature worthy of notice was that after the failure of soap-and-water enemata two ounces of castor oil mixed with four of olive oil proved effective. During the discussion of the paper Dr. Taylor said that the value of morphia in peritonitis depended on the inflammation not being of septic origin, in which class of cases it was useless. He had himself given thirteen grains in seven hours.

REMANDING LUNATICS TO WORKHOUSES.

MR. BARSTOW, the sitting magistrate at Clerkenwell, thinks he has solved the difficulty about remanding lunatics to workhouses by making a *deferred* order for the admission of a lunatic to an asylum and meanwhile ordering the lunatic to be detained in the workhouse. The question arises whether the effect of this form of order is to *compel* the master of a workhouse to admit the lunatic, or whether it simply removes the hesitation to admit because there is a guarantee that the lunatic will not remain long.

"SINGULAR MEDICAL EVIDENCE."

SUCH is the heading of the description of an inquest recently held by Sir J. Humphreys on the body of a man who succumbed to injuries received in "the fatal fight at Poplar," given by our contemporary, the *Echo*. If one or two of the facts recorded were really deposed to by the surgeon who made the post-mortem examination, we should be inclined to subscribe to the opinion that they were, to say the least, somewhat unusual. Mr. Leslie is reported to have said that about *one pint and a half* of thick fluid blood was found beneath the skull cap. His evidence we think has been either misrepresented, or he used the expression as a figure of speech. At the same time we entirely agree with Mr. Leslie that shock produced directly by a blow, and indirectly by mental excitement, must be admitted as a possible factor in causing extensive effusion of blood within the skull. But, apart from this consideration, there is strong circumstantial evidence that the meningeal hæmorrhage was of traumatic origin, for the scalp was markedly ecchymosed, and there was much sanguineous effusion between it and the bone.

THE COMING ELECTION AT THE COLLEGE OF SURGEONS.

IN addition to Mr. Savory, who offers himself for re-election, there are at present only three candidates for election to the Council of the College—Messrs. F. J. Gant, G. Cowell, and Oliver Pemberton. We understand that it is not the intention of Mr. T. Holmes to seek re-election. Applications must reach the secretary on Monday next.

PROPOSAL TO RATE HOSPITALS IN LIVERPOOL.

IT is devoutly to be hoped that the proposal to rate hospitals in Liverpool will be abandoned. How can such a proposal be justified? The medical institutions relieve the rates. By saving the health and life of breadwinners, or by receiving those cases which otherwise would have to be treated in Poor-law infirmaries, they indirectly and directly save the rates. It is alleged that sixty-four charities in Liverpool do so to the amount of £144,000. To tax them would be to discourage all the amenities of hospital charity, which would be a grievous misfortune in any town, but especially in such a town as Liverpool.

DEATH OF J. MONCRIEFF ARNOTT, F.R.S.

THE death is announced, at the age of ninety-one, of James Moncrieff Arnott, F.R.S., F.R.C.S., Surgeon Extraordinary to the Queen. The deceased gentleman occupied a seat at the General Medical Council Board from 1860 to 1865, and was for many years a member of the Council and of the Board of Examiners of the Royal College of Surgeons.

HEALTH MATTERS IN PERU.

THE authorities of Trujillo, an important city in Peru, have, we are glad to learn, been bestirring themselves to improve the sanitary condition of the locality; the refuse heaps which used to be allowed to poison the suburbs have now disappeared, and a healthy promenade is to be laid out with rich and fragrant plants on what was formerly little better than a great cesspit. A new hospital, too, is being built, and will be a marked improvement upon the old one. A complaint is made in the local medical journal that the investigation of such circumstances as the death of a woman in labour, where an irregular practitioner had violently manipulated a shoulder presentation, is extremely difficult in Peru.

HÆMOPTYSIS IN SYPHILIS.

DR. A. W. REYES, in the *Eco Cientifico*, a Cuban medical journal, mentions some cases of hæmoptysis occurring in the second stage of syphilis during treatment by the green iodide of mercury. In one case the hæmoptysis disappeared when the iodide was stopped, and recurred each time this drug was recommenced, so that Dr. Reyes suggests that in some persons the plasticity of the blood is so diminished by this preparation that either by its independent action or by its augmentation of that of the disease it produces a fatty degeneration of the capillaries of the respiratory passages, so giving rise to rupture and hæmorrhage.

DEATH OF SIR WILLIAM MUIR, K.C.B.

WE regret to have to announce the death of Sir Wm. Muir, M.D.Ed., K.C.B., late Director-General of the Army Medical Department, which took place, after a long illness, on the 2nd inst.

RABBETH MEMORIAL FUND.

THE final meeting of the committee of this fund was held at King's College on June 2nd, and the treasurers were empowered to divide the balance of £800 between the Royal Free and King's College Hospitals.

IT is rumoured that his Excellency Earl Spencer will shortly appoint a commissioner to inquire into the management of the House of Industry Hospitals in Dublin.

Pharmacology and Therapeutics.

EXPERIMENTAL RESEARCHES ON ANTIPYRIN.

PROFESSOR GIUSEPPE CESARI has published the results of some important researches on antipyrin made in the laboratory of experimental pharmacology in the University of Modena. In frogs, a single dose of from three to four centigrammes injected under the skin produced in about a quarter of an hour dilatation of the pupil. Reflex irritability was at first diminished, then gradually increased; the respirations became slower and then irregular, being finally arrested. At last mydriasis appeared, together with some exaggeration of reflex irritability, persisting for several days. With doses of from five to ten centigrammes the mydriasis set in rapidly and was more complete; there were paralysis, spasmodic contractions, mostly of a tonic type in the anterior and of a clonic in the posterior extremities, exaggeration of reflex, suspension of respiration, and insensibility of the cornea; finally, death, with arrest of the heart in diastole, occurred in from two to twenty-four hours. In rabbits, as much as sixty centigrammes in one dose, or in two doses at an interval, did not occasion much disturbance to the animal; generally the antithermic action showed itself in about half an hour. Injected in doses of a gramme, in an hour the temperature was decidedly diminished, and in from one to two hours it was greatly reduced; there was muscular twitching, general tremor, wagging of the head, suspension of reflex, and slight paralysis of the limbs, especially of the anterior extremity; these phenomena disappearing one after another in six or seven hours after the injection. When two or more grammes were injected in a single dose the antithermic action was more rapid and more powerful, reducing the temperature nearly 4° C.; there was complete dilatation of the pupil and marked hyperæmia of the ear; collapse occurred quickly, and in one or two hours after the introduction of the drug the animal was seized with convulsions, increasing in severity and duration, mostly of a tonic character in the anterior and of a clonic in the posterior extremities, which convulsions were repeated with still greater intensity on the application of the interrupted galvanic current, with marked retraction of the head on the back. In these doses antipyrin generally caused death in rabbits in about five hours. In dogs, antipyrin, injected in doses of from two to three grammes, caused in an hour or rather more a copious white salivary secretion, accompanied by attempts at vomiting, and then by vomiting of alimentary substances, with more or less prostration, general trembling, especially of the posterior limbs, whining, and fits of restlessness; then dilatation of the pupil was observed, extreme and persistent with a three-gramme dose, in which case the reduction of temperature was somewhat greater than if a dose of from a few decimals to two grammes was given, between which limits the reduction varied but little. The respirations and cardiac beats gradually increased, and sometimes returned simultaneously almost to normal. In the human subject, antipyrin administered by the mouth in doses of from one to two grammes, repeated till four grammes had been taken during the space of at least three or four hours, always reduced the temperature from a few decimals to 2°. There was often produced almost immediately a sense of heat in the face, sometimes a slight moisture of the skin, and more rarely sweating. In exceptional cases it produced a kind of coryza of short duration, and vomiting. The pulse and respirations rose and fell with the temperature. The drug could be detected in the urine.

VERBASCUM.

From time immemorial verbascum has enjoyed considerable reputation as a remedy for phthisis. The Irish peasants employ by preference the leaves of the large Verbascum thapsus. They use 100 grammes of the fresh leaves or thirty of the dried in a litre of fresh goat's milk: this mixture, allowed to macerate for ten minutes, is then filtered, sweetened, and drunk warm. Two or three litres are consumed every day. Dr. Quinlan has tried this treatment for a period of two years in 127 patients. He believes that in the premonitory and "pretubercular" stage of consumption the remedy possesses curative and nutritive properties more marked than those of cod-liver oil, and nearly equal to those of koumiss. The increase of body weight is certainly due to the verbascum, since the milk alone does not yield the same results. The remedy effectually relieves cough, checks diarrhœa, and alleviates all the symptoms of consumption except the sweatings. The leaves smoked like tobacco relieve the symptoms of irritation of the respiratory passages.

MYOCTONINE.

Myoctonine and lyaconitine are the names given to two substances separated from the yellow-flowered Aconitum lycoctonum by Messrs. Dragendorff and Spon (*Pharmaceutical Journal*). Myoctonine has been physiologically investigated by Herr Salmonowitz. It is a yellowish, bitter, amorphous powder, which dissolves easily in chloroform, absolute alcohol, and benzene. It is a powerful poison, resembling curare in its action, and acts mostly energetically when introduced directly into the circulation.

WALNUT-TREE BARK.

J. C. Ugaz, writing in the *Cronica Médica* of Lima, calls attention to the vesicating property of the inner bark of the walnut-tree. He cut a square of about two inches each way, stripped off the outer bark, macerated it in vinegar for a quarter of an hour, and applied it to his arm on going to bed. He was disturbed in his sleep by the discomfort produced, but, wishing to carry out the experiment, controlled himself. After about an hour he awoke in severe pain, and tore off the bandage and piece of bark. In the morning there was no pain, but three large blisters filled with serum and covered with a blackened skin had appeared. The writer also applied the bark to the lip of a boy suffering from hypertrophic lupus, and dusted the blister with calomel. He did not see the boy for eighteen days, and when the latter returned he was completely cured. Señor Ugaz asks, "Can walnut and calomel be specifics for lupus?"

EUODIA LONGIFOLIA.

The *Pharmaceutical Journal* states that the leaves of a rutaceous plant, Euodia longifolia, a native of Fiji, have been successfully employed by native women as a preventive of miscarriage. The infusion of the leaves is used for several months previous to parturition. It is made in a most effectual manner by rubbing the leaves into a pulp with cocoa-nut milk, adding more liquid and then straining, the resulting greenish mixture forming the medicine.

PURGATIVES.

The plant Leonotis leonurus, a native of Turkey and the Cape, possesses purgative properties, and is used in the form of decoction as an emmenagogue. The leaves of Ipomœa pandurata also contain a purgative resin.

CORNUTINE AND ERGOTININE.

In a recent memoir M. Kobert announced the discovery of three new principles in ergot of rye—ergotinic acid, sphacelinic acid, and cornutine. Kobert did not state that he had prepared these three bodies in a state of chemical purity, but maintained that each had a special physiological action. M. Tanret has re-investigated the question. According to him, cornutine is but ergotinine somewhat altered by exposure to the air. If an acidulated solution of ergotinine be exposed for a longer or shorter time to the air, it becomes more and more coloured, and acquires all the characters of cornutine. The transformation takes place more rapidly under the influence of heat. The experiments of M. Dujardin-

Beaumetz, M. Budin, and Chahbazian prove that ergotinine is a powerful medicinal agent, the administration of which may be attended by severe toxic effects.

COCAINE AS AN ANODYNE.

If a saturated solution of hydrochlorate of cocaine in strong nitric acid be applied to the skin, instead of the painful smarting of the acid alone, a slight pricking sensation is the only sensory effect produced. An eschar is formed, but takes a longer time to appear than if the nitric acid be used alone. These results have been obtained by Messrs. Randolph and Dixon (*Pharmaceutical Journal*).

AGARICIN IN THE SWEATING OF PHTHISIS.

Professor Masius of Liège, in a clinical lecture recently delivered, mentions the favourable results he had obtained by the use of agaricin in the excessive sweating of phthisis. He began with a single dose of five milligrammes, and followed this up with increased doses of ten and eleven milligrammes. In some cases the five-milligramme dose was ordered morning and evening.

THE BACILLUS OF CHOLERA.

DR. E. VAN ERMENGEN, who was despatched by the Belgian Government last year to investigate the cholera at Marseilles, has published his report,[1] with many additions and illustrations, forming a monograph of some 350 pages. We have previously had occasion to mention Dr. van Ermengen's researches, which entirely corroborated the conclusions arrived at by Dr. Koch; and the volume before us practically consists of a thorough and extensive survey of all the facts which bear upon the famous "comma bacillus," including detailed analysis and criticism of the numerous observations made by others upon the subject during the past year. The first part of the report consists of an account of the manner in which the author fulfilled his mission. His first business was to proceed to Paris, where he visited M. Pasteur's laboratory, and was shown many preparations by Dr. Roux, who had recently come from Toulon, where he had been studying cholera with M. Strauss. Their specimens exhibited the comma-shaped bacillus of Koch, but they declared that such organisms were not invariably present in the choleraic intestine and evacuations. Arrived at Marseilles on the 10th of August, Dr. van Ermengen was enabled to pursue his researches in the laboratory that had been placed at the disposal of MM. Nicati and Rietsch. He thus arrived at the conviction that the "microbe of Koch possesses specific characters, as shown on cultivation," and on his return to Belgium he proceeded to Berlin, where he completed his knowledge of the subject under the guidance of Dr. Koch. He then devoted his whole time to the task of verifying and extending his researches, the result of which is to be found in the pages of the report, which we may briefly summarise.

The morphological characters of the bacillus are fully described, and the variations in them according to the nature of the media in which the organism is cultivated and the stage of its development. The author expresses a preference for methyl-blue staining, and appends numerous photograms of the actual preparations. The microbe, in his opinion, is more allied to spirillum than to other bacteria; and he points out that it is endowed with very active motility, which is much influenced by temperature. For the movements, mostly undulatory and best seen in broth or serum cultures, are arrested by a temperature of about 16° C., whilst they are very active at the temperature of the blood. The characteristic appearances shown in the gelatine cultures are of course dwelt upon, and also the behaviour of the microbe when cultivated in other media, as agar-agar, coagulated serum, and fluid media, as broth and fluid serum. Although the appearance of these fluid cultures is not distinctive, they are useful for showing the rapidity with which the comma bacilli may develop. He also succeeded in cultivating the microbe in milk, potato, and slightly acid fruits, but found that it did not grow in wines and beers rich in alcohol, or containing a certain amount of acetic acid. The biological characters of the micro-organism are next discussed; its remarkable power of multiplication, and its vitality under favourable conditions of temperature and moisture. A limit is, however, soon placed to this fecundity by the absence of oxygen or the noxious influence of putrefactive changes. The influence of chemical agents, of especial importance in estimating the value of disinfectants, is also described. The author has not been able to ascertain that the organism produces spores, for he shows that the bodies simulating such spores are infertile and probably degenerate fragments. Nor does he think it necessary that they should possess this mode of generation in view of the conditions under which they exist; and he regards the absence of sporulation as a further mark of distinction from the class of bacilli, and of alliance with that of the spirilla. A long note at the end of the volume again discusses this point, to which greater prominence has been given by the statements of Ferran. Dr. van Ermengen has taken the pains to investigate Ferran's work, and is enabled to confirm some of his statements, which go beyond those of Koch in a demonstration of a complete developmental cycle of the comma bacillus when cultivated in a special manner. The inferences drawn by Ferran from observing the presence of globular bodies in connexion with the spiral filaments—viz., that there is evidence of spore formation and a mode of reproduction which entitles the microbe to a higher place in the class of fungi than the schizomycetes—are not admitted by van Ermengen, who cautiously says that the matter is open for further investigation. As to Ferran's alleged discovery of an attenuated virus that is capable of conferring immunity on inoculated subjects, we are told that a commission of inquiry has been appointed by the Brussels Academy of Medicine. "And if," writes van Ermengen, "these discoveries be proved to be true, then the pathogenic power of Koch's comma bacillus will henceforth rest on demonstrations which will be beyond cavil, for it will have been proved upon man himself. As to the discovery of a preservative cholera vaccine, which to some may seem too good to be true, may it one day be established with all needful experimental rigour, and shed eternal honour on the microbiologist who was the first to foresee its probability!" Returning to the body of the work, we find a discussion of the proofs upon which the cholerigenic powers of the bacillus are based, with the remark that if such proofs solely rested upon the inoculability of animals, the microbic nature of many diseases would still be doubtful. The first place in such testimony must, however, be accorded to the invariable and exclusive occurrence of the bacilli in relation to cholera. Inoculation experiments have, however, advanced the subject beyond this stage, for, setting aside Ferran's assertions as being yet unconfirmed, there has been accumulated abundant evidence of successful inoculations in guinea-pigs. Many of these are quoted by van Ermengen, who has contributed much to the question himself. He then proceeds to discuss the arguments and facts advanced against Koch's doctrine, especially those of Lewis, and of Finckler and Prior. He demonstrates, what is now generally accepted, that the curved organisms described in other conditions and diseases than Asiatic cholera, by these and other observers, differ notably in their biological characters from the bacillus of Koch. In a supplementary note Emmerich's discovery of a bacterium in the blood and tissues of choleraic subjects is subjected to detailed criticism; but the observations of Drs. Klein and Gibbes are held to be sufficiently refuted on the same grounds as those on which the statements of Finckler and Prior are met.

Dr. van Ermengen in the third part of his work proceeds to show how the adoption of the comma bacillus as the cause of cholera harmonises with known facts of the disease; and he employs for this purpose a sort of running commentary upon an address of the epidemiologist, Dr. Lefebvre, before the Brussels Academy, which embodied the accepted teachings on the pathogeny of the disease. This most interesting chapter, which space will not allow us to abstract, is followed by another on the practical deductions from the adoption of Koch's teaching. First, there is the need for the institution of bacteriological laboratories and the instruction of medical officers in the methods of detection and verification of micro-organisms, on the view that Koch's discovery his furnished the means of making a certain diagnosis of the disease and of enabling the authorities to be warned of the occurrence of cholera in time to take measures for preventing its spread. Such measures would include a strict supervision of the frontier, compulsory notification of suspected cases, the formation of sanitary committees, the appointment of public disinfectors, institution of hospitals, prohibition of imports of fruits, vegetables, &c., from infected countries, and the rigorous supervision of laundries, dairies, &c. The various modes of disinfection are discussed in detail: physical agencies—as desiccation, dry and moist heat; chemical agents, including gaseous disinfectants—as bromine and chlorine, and fumigations with sulphur, &c.; fluid disinfectants, restricting the term only to those agents which within half an hour destroy all choleraic microbes under all circumstances—as corrosive sublimate and carbolic acid, sulphate of copper, chloride of lime and sulphate of iron, salicylic, boric and thymic acids, laudanum (1 per cent. kills the bacilli), and chloroform (1 in 30 or 40), alcohol (1 in 10). Observations follow confirmatory of Koch's statement as to the destructive action of putrefaction upon the comma bacilli; and the less need for vain attempts at disinfecting latrines with the view of destroying the cholera virus. The importance of disinfecting the excreta, for which a 5 per cent. solution of carbolic acid is advised, and the need for obtaining pure supplies of water and food, are insisted on. The whole argument is summed up in conclusions which we regret not to be able to reproduce in detail. Suffice it to quote the following:—

---

[1] Recherches sur le Microbe du Choléra Asiatique. Rapport présenté à M. le Ministre de l'Intérieur. Par le Dr. E. van Ermengen. Paris: G. Carré. Bruxelles: A. Manceaux. 1885.

"17. The discovery of the comma bacillus is of the greatest importance for diagnosing choleriform attacks of doubtful nature which are produced at the commencement of epidemics, and for the institution of prophylactic measures, the more efficacious because such early diagnosis enables them to be undertaken in time.

"18. The application of bacterioscopic processes for the diagnosis of true cholera does not present any serious practical difficulties, and it would be extremely desirable, in view of the serious threats of an invasion of Belgium by cholera, that a sufficient number of medical men appointed to the sanitary service should be initiated therein with as brief delay as possible.

"19. The knowledge of the biological properties of the choleraic microbe, of its feeble resistance to desiccation, and of the absence of a stage of spore-formation, affords valuable facts for prophylaxis. It places a limit on the excessive use of disinfection, and puts us in possession of the simplest and surest means of combating its effects."

The monograph is furnished with several appendices, and it is further admirably illustrated. Whatever be the final outcome of the question, this work of Dr. van Ermengen's will rank as one of the most important contributions to the history of the scientific investigation of the pathogeny of cholera.

THE SANITARY CONFERENCE AT ROME.

SINCE our last notice of the proceedings of the International Sanitary Conference at Rome some substantial work has been done by the Technical Commission, which is preparing a series of resolutions for submission to the entire Conference, when this body, which includes the diplomatic representatives, meets again. After voting that quarantine measures by land were impracticable and hence useless, the Commission proceeded to discuss the question of maritime quarantine. The discussion on this point was maintained at considerable length, the actual proposition before the Commission being one by Dr. Sternberg (United States of America), to the effect that an arbitrary time quarantine for vessels arriving from infected or suspected countries was not justifiable. During the course of the discussion, which took place on Monday, May 25th, Dr. Koch (Germany) suggested that a difference should be made between ordinary passenger ships and vessels conveying either troops or emigrants in large masses. Later on, the English and Indian delegates, who were evidently in sympathy with the proposition of Dr. Sternberg, were requested to explain the system which in England had superseded quarantine; and the system of medical inspection coupled with the immediate isolation of the sick was then fully set out by Dr. Thorne Thorne (Great Britain), who contended that his country was the only one that had loyally carried out the full intentions of the Vienna Conference of 1874 in this respect. Sir Joseph Fayrer (India) maintained that there was no proof that a vessel sailing from India had ever conveyed cholera into any European country. Dr. Rochard (France) held a different opinion, but on being asked by the Indian delegates to name the circumstances justifying this view, no answer was apparently forthcoming. Several delegates, such as the Brazilian, felt that the subject required further elucidation and study.

At the sitting of Wednesday, May 27th, Dr. Proust (France), with a view of defining more precisely the points to be debated, submitted a scheme dealing first with the measures of prevention at the ports of departure, then with the sea passage, and lastly with the ports of arrival. This being unanimously accepted as the basis of discussion, Dr. Sternberg (United States) proposed that in all ports medical officers appointed by the consuls should have power to inquire into the sanitary state of the port and shipping. Owing to the abstentions this was lost. Dr. da Silva di Amado (Portugal) proposed that, since the consuls had to endorse the documents relating to the freedom from disease in ports, they ought to be allowed to take part in the inspection of the sanitary state of vessels leaving for the ports of countries they severally represented. The abstentions were again numerous, but a small majority carried the proposition. Dr. Proust's proposals were next considered. The first related to measures of sanitation to be adopted at ports of departure whenever cholera was prevalent. The lading of vessels was only to be effected after cleansing, and, if need be, disinfection of the holds, &c.; and the medical officer of the ship, who in the case of all infected ports was to be approved and maintained by the Government, was, together with the captain, to certify as to the proper sanitary state of the vessel. Passengers were always to be examined before embarking, and all sick of cholera or suspected persons were to be refused. Luggage, linen, &c., was to be carefully looked after, and, if need be, disinfected, the clothing of persons having suffered from cholera being always disinfected. Any case of cholera occurring on board during the stay in the port was to be immediately removed to hospital, cleansing and disinfection of the ship, &c., to follow.

On Friday, the 29th, a number of resolutions were passed with reference to the action to be taken as to suspected ships during the sea passage. They related mainly to measures of cleanliness, disinfection, and ventilation, and received an all but unanimous assent. These resolutions were followed by others relating to ships actually suffering from cholera during the passage, and they were in the main such as have long been adopted in this country.

At the sitting on Saturday, the 30th, a series of proposals formulated by a subcommittee with reference to the passage of vessels from the East to the Mediterranean by the Red Sea and the Suez Canal, were submitted for discussion. They were taken *seriatim*. The first related to a compulsory medical inspection at Suez by an officer to be appointed by some International Commission, and who would have authority to decide if the vessel was to be regarded as "suspect" or not. If not, it would at once pass the canal freely. The British and Indian delegates opposed this. Sir Joseph Fayrer explained that he and his colleagues were in no way opposed to inspection for the mere purpose of ascertaining the state of health on board; but he refused to allow that any locally appointed medical officer should supersede a British medical officer in deciding whether anyone on board an English ship was suspected of having some choleraic affection or not. Sir G. Hunter demanded that British ships should, under all circumstances, have free passage through the Suez Canal, provided they did not touch the shore. This was refused. Dr. Thorne maintained that the proposal of the subcommittee was not one of inspection only, but that it was the first step towards the imposition of quarantine, which England had opposed, and which had been proved to be useless. The proposal was, however, carried by a large majority of delegates. Later on it was proposed that if the visiting medical officer suspected any case of cholera on board any ship, all passengers and crew should be landed, and that the ship should be detained for five days to see if any further case occurred. Dr. Lewis at some length contended that the danger did not lie in shipping, and that although cholera always prevailed in India, a country with which Australia was in constant communication, yet that the disease had never been conveyed to Australia. Other delegates demanded a much [illegible] period than five days, the Spanish delegate insisting on at least ten days after the last case had occurred amongst those landed. Sir Joseph Fayrer once more offered all information at Suez, so that local officials could report to their respective Governments, and Dr. Thorne maintained that if vast masses of passengers and crews were landed in the horrible lazarets of the Red Sea shore, disease would not be stayed, but spread; also that we had no right to deposit in the midst of Egyptian populations that which we feared to receive on our own shores. The Conference had, however, decided in favour of the quarantine system, and the detention of all passengers with suspected cases on board was carried by a large majority. Some abstained from voting.

Several subcommittees are at work daily, as well as the Technical Commission. The subcommittees are dealing with disinfectants, regulations as to small vessels, pilgrimages, &c.

On Wednesday, the 27th, his Majesty the King of Italy gave a State banquet to the members of the Conference. Before the banquet the presentations were made, and the king then conversed for some time with each of his guests. The diplomatic corps and the officers of the king's household attended the dinner.

POOR-LAW MANAGEMENT IN ST. PANCRAS.

MR. T. ECCLESTON GIBB, who has just resigned the office of clerk to the guardians of St. Pancras, has issued an interesting statement on Poor-law management in that parish during the last five years. In this period much effort has been made to prevent out-door relief becoming the means of pauperising those who are in necessitous circumstances. In the form of medical out-door relief State aid presents the first opportunity for the poor to become dependent; it is, as Mr. Gibb says, the first downward step in the career of pauperism, and the need for intelligent relieving officers is therefore urgent. During the last five years the amount expended upon out-door relief has been gradually reduced by more than one-third. This reduction has been brought about by a rearrangement of the duties of relieving officers, giving better opportunity for a more thorough investigation into the condition of those applying for assistance, by a recognition of the principle that destitution and not simply poverty is the only claim to relief that the law recognises, and further, by offering to applicants admission into the workhouse, instead of granting a dole which is in practice insufficient for their maintenance. The effect has naturally been to increase the expense of in-door relief, but Mr. Gibb tells us that scarcely one-fifth of the applicants for relief who were offered an order for the workhouse accepted it, the remainder, with few exceptions, having gone on without any relief at all. The extra cost has not therefore been excessive, and in its effect upon the parish has been distinctly beneficial, for while the cost of out-door relief falls upon the parish, that of in-door relief is partially chargeable to the common poor fund. The same principle has been adopted in the case of widows with children; it has often been found sufficient to remove one or two of the children to the schools at Leavesden to enable the mother to maintain the rest of her family; and this is obviously a far better course than the administration of out-door relief, which would educate all the children in the knowledge that they could always rely upon the same agency for assistance whenever it was required. Here, again, the operation of the common poor fund is beneficial in encouraging the guardians to maintain children in suitable schools, for while the cost of maintenance under these circumstances, together with a share in the salaries and other expenses, is chargeable upon the common fund, every child maintained in the workhouse deprives the guardians not only of fivepence per day in respect of each child, but also the amount which might have been recovered had the place of the child in the workhouse been occupied by an adult.

After referring to the savings thus effected, Mr. Gibb points out how they have been lost by an increase of expenditure over which the guardians have no control; thus, the sum paid to the Metropolitan Asylums Board has during the last four years been at the rate of more than £10,000 a year more than in the previous four years; and the whole of this has arisen through that Board receiving into its hospitals for infectious disease persons who were not paupers. Again, the care of lunatics has during the latter period entailed an increased cost of over £2000 a year.

Mr. Gibb leaves his readers to draw their own conclusions from his story. Upon the judicious administration of poor relief depends whether the assistance given to necessitous persons shall be beneficial or responsible for considerable harm: It is within the power of the ratepayers to elect representatives who will properly appreciate their duties in this respect, or, as often in past times, to leave the control of poor relief in the hands of those who will receive in payment of rent the sums which have been given to the poor.

IRISH MEDICAL ASSOCIATION.

THE annual meeting of this Association was held on the 1st inst., the chair being occupied by the President, Dr. Hemphill. The Council in their report referred to the Medical Act Amendment Bill, and to a revision of the law relating to superannuation of Poor-law medical officers, neither of which do they expect will come before Parliament this session. The question as to whether medical officers of health are entitled to special remuneration for inspecting labourers' dwellings and reporting on their condition has, after a prolonged struggle and considerable expense, been finally settled in a satisfactory manner by the Court of Appeal. The report also referred to several cases in which prison surgeons were summoned from country districts to give evidence before the Prisons Commission in Dublin, and were compelled to pay the substitutes appointed to discharge their duties *during their absence, and this though in one* instance the judge of assizes ruled that the authorities, and not the surgeon were liable. The report was adopted, also the following resolutions:—

"That the council be instructed afresh to continue to urge the Government to adopt the amendments of the Medical Act Amendment Bill approved of by this Association, including one securing uniformity of final examination fee, and that, in the event of such amendments as seem to them necessary not being introduced into the future Bill, the support of this Association shall not be given to that measure. That this Association, having observed with great regret that, in consequence of the persistently continued opposition given to it by certain members for Irish constituencies, the Union Officers' Superannuation Bill has not been pressed upon the attention of Parliament, again asserts its opinion that the Poor-law medical officer is entitled, in equity, to receive a pension, as a matter of right, whenever he shall be incapacitated from the discharge of his duty. *This Association therefore earnestly* urges the Government to exercise its influence to pass a measure so generally approved and admittedly so just in its principle; and furthermore desires that the council will continue to use its best endeavours to have such a measure promoted on every opportune occasion. That this Association desires to express its great gratification at the success of the measures taken by the council in establishing in the law courts the right of medical officers of health to payment for their services under the Labourers (Ireland) Act, as well as in vindicating many other principles important to the profession in Ireland."

The members and several guests dined together in the Albert Hall of the Royal College of Surgeons in Ireland, presided over by the President for the ensuing year, Dr. Edward Hamilton.

CHOLERA IN JAPAN.

THE report of the director of the Central Sanitary Bureau of Japan upon the epidemic of cholera which occurred in that country in 1879 has just been published. It contains a short history of the disease in Japan in that year, an account of the operations then carried out by the Home Department in connexion therewith, and the imperial decrees and Government notifications *bearing on* the same subject. The disease first showed itself on March 14th, and the last case occurred on December 27th; the first appearance of cholera in Japan having been in 1877. The total number of persons attacked was 162,637; *the* deaths amounted to 105,786. The original returns from each of the prefectures are so diffuse that their compilation would form a bulky volume, *consequently* only certain items have been selected from them and published in this report. All the original returns, however, are kept in the Sanitary Bureau for reference. The decrees published by the Government with the view of checking the spread of the disorder contain precise directions as to the immediate notification of the existence of a case of cholera to the local authorities of the place in which it has occurred, rules as to quarantine, the removal and disposal of the dead, and the disinfection of all polluted articles, for which latter purpose the inspecting officers in a locality infected with cholera were directed at any time to furnish to an applicant any of the various kinds of disinfectants at a certain fixed price; the poor, however, were to be supplied gratuitously. At the close of the epidemic rewards were granted to the officials who had had the management of affairs connected with the precautionary measures, and compensation to those who had been attacked by the disease, and the expenses incurred in the burial of officials who had been carried off by it were refunded to their families. The reason for the adoption of these rules was that it had been found that a large number of such officials had either died of the disease or had undergone great sufferings from it. Substantial recognition of their services was also awarded to all medical men who had been attacked with cholera while devoting themselves to their duties of attending upon and treating patients suffering from the disease.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bedford Union Rural Sanitary Authority.—The annual report states that the estimated population of this district is 23,670, and the death-rate for 1884 is a fraction over 16 per 1000, the deaths of children under one year being as low as 18 per cent. of the total deaths; the birth-rate was 31 per 1000. Under the heading of diseases of the year, Dr. Prior gives a brief account of the mortality from the principal zymotic diseases. Small-pox and measles have been comparatively absent; scarlet fever has prevailed in several parishes, but only two deaths have been registered from this cause; diphtheria caused fifteen deaths, Dr. Prior stating that some of these might have been prevented had parents been willing to allow their children to be moved to hospital. Four outbreaks of enteric fever occurred during the year; in each case it is believed that the disease arose as the result of impure drinking water. The report of the sanitary condition of the district is somewhat meagre.

Northampton.—The death-rate of this borough in 1884 was 17·8 per 1000 calculated upon an estimated population of 55,930; the birth-rate was 34·36 per 1000. Diarrhœa caused an increased death-rate among children under one year of age, the proportion of deaths at this period of life to deaths at all ages being 35·8 to the 100. Small-pox caused no death, but one case was imported from Homerton, giving rise to two others. With the exception of diarrhœa, already mentioned, the deaths from zymotic diseases were few, typhoid fever and diphtheria, however, prevailed somewhat more extensively than in previous years. Reference is made to the failure of the water-supply to the town during the summer months; for days together in some parts the inhabitants could not procure any water at all; the control of the town water-supply having passed into the hands of the Corporation, Dr. Cogan urges upon the Council the necessity for making further provision. The sewers in several streets have been reconstructed, evidently not before this was required. Improvements and alterations have been made in a number of houses, and in many others the drains have been connected with the sewers. Dr. Cogan calls attention to the need for controlling the drainage in newly built houses on account of the frequent nuisances therein arising from drainage defects, and he recommends the Council to adopt building regulations similar to those published by the Local Government Board. During the year a considerable number of nuisances have been abated, relating chiefly to defective drains, dirty houses, and the improper keeping of animals. Various kinds of diseased meat were destroyed as being unfit for human food, and two persons were convicted for exposing for sale meat in this condition.

Hexham (Rural).—The Hexham Union comprises a population of 34,086, of which all but 5919 inhabitants of the town of Hexham are under the jurisdiction of the rural sanitary authority. In consequence of the appearance of cholera in Europe, attention has been given in this district to the water-supplies, and during the summer in some villages work was carried out with the object of increasing the amount. Small-pox and typhus fever were almost absent, only one case of each being reported during the year. Enteric fever, scarlet fever, and diphtheria were, however, more prevalent, although not appearing in epidemic form. The death-rate during the year was 16·1 per 1000, deaths from diseases of the zymotic class being 8·4 per cent. of the total deaths and 1·3 per 1000 of population; the deaths of children under one year of age being 20·4 per cent. of total deaths.

Llanelly (Rural).—Dr. Thomas gives a brief account of the procedure adopted in this district for dealing with infectious diseases, and regrets the absence of any hospital in which cases can be satisfactorily isolated. Disinfection is, however, carried out, and infected bedding and clothes burnt when necessary. Referring to the bye-laws which provide for the removal of all privy accumulation once a week, and of house refuse twice a week, he urges the strict enforcement of these regulations. Several cottages in which typhoid fever appeared were found in so unsatisfactory a condition that they had to be closed and demolished. An outbreak of diphtheria occurred among children attending a school which was found in a bad sanitary condition, especially as regards the privies and the ventilation; these were remedied, and no subsequent cases occurred. Dysentery also broke out among the children of a farmhouse, which was attributed to the drinking of drainage-water from some marshy land. Phthisis was prevalent, the result, Dr. Thomas believes, of living in "damp, dark, ill-ventilated cottages." An interesting story is told of the pollution of drinking water by its passage through galvanised iron pipes, the carbonic acid of the water dissolving the zinc; analysis showed that in each gallon of this water there were 6·4 grains of carbonate of zinc in solution. The death-rate for the whole district, which has a population of 26,800, was 15·66 per 1000 during the year; that of children under one year being 12·36 per 100 births, and 26·92 per 100 deaths.

Kingston-on-Thames (Urban).—The report on the sanitary condition of the borough of Kingston-on-Thames during 1884 shows that, based upon an estimated population of 21,912, the birth-rate was 32·4, and the death-rate, after excluding those deaths in the union workhouse not belonging to the borough, 16·3 per 1000. This death-rate showed a slight decline from the rates recorded in the borough in the preceding three years, which were 17·0, 16·7, and 16·9 respectively. The mean rate in the six years 1879-84 was 17·2, which is a comparatively low rate for an urban district, but cannot be estimated at its true value without due consideration of the age distribution of the population and the calculation of death-rates at groups of ages. The rate of infant mortality, measured by the proportion of deaths under one year to registered births, was equal to 122 per 1000, which is disproportionally high compared with the death-rate at all ages. This comparatively high rate of infant mortality appears to have been due partly to the epidemic prevalence of measles in the spring and to excessive diarrhœa fatality in the summer. The death-rate from zymotic diseases was also higher than it should be in a population having a rate from all causes not exceeding 16·3, and was equal to 2·37 per 1000; the zymotic rate, however, was somewhat lower than the rate from the same causes in the outer ring of metropolitan suburban districts, or in England and Wales generally. The 52 deaths from zymotic diseases in Kingston last year included 16 from measles, 17 from diarrhœa, and 9 from diphtheria. The mortality from measles and diphtheria exceeded the average for all England, while that from all the other zymotic diseases was below the average. The medical officer of health (Mr. E. M. Shirtliff) again points out the disadvantages under which the sanitary organisation of the district labours through the want of hospital accommodation for infectious diseases and of a disinfecting oven. Apart from the constant risk of the importation of small-pox from London, hospital accommodation affords the only really efficient means for controlling an outbreak of scarlet fever. The high rate of mortality from diphtheria is attributed to the escape of sewer gas into the houses, through inefficient ventilation of sewers, and of soil-pipes in the house.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 4893 births and 3590 deaths were registered during the week ending May 30th. The annual death-rate in these towns, which had been equal to 20·4 and 21·1 per 1000 in the preceding two weeks, declined again last week to 21·0. During the first eight weeks of the current quarter the death-rate in these towns averaged 21·9 per 1000, against 22·7, the mean rate in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 14·6 in Brighton, 15·5 in Halifax, 15·7 in Derby, and 17·8 in Nottingham. The rates in the other towns ranged upwards to 28·5 in Cardiff, 28·7 in Blackburn, 29·6 in Newcastle-upon-Tyne, and 34·3 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 463 and 510 in the previous two weeks, declined again to 487 last week; they included 174 from measles, 125 from whooping-cough, 56 from diarrhœa, 43 from small-pox, 32 from "fever" (principally enteric), 31 from diphtheria, and 26 from scarlet fever. These zymotic diseases caused the lowest death-rates last week in Brighton and Bolton, and the highest in Blackburn, Preston, and Cardiff. The greatest mortality from measles occurred in Manchester, Birkenhead, and Newcastle-upon-Tyne; and from whooping-cough in Oldham, Preston, Cardiff, and Blackburn. The death-rates from "fever" and scarlet fever were exceptionally low. The 31 deaths from diphtheria in the twenty-eight towns included 17 in London, 4 in Cardiff, and 3 in Portsmouth. Small-pox caused 69 deaths in London and its outer ring (inclusive of 17 in the metropolitan asylum hospital ships and camp at Darenth), 1 in Bristol, 1 in Manchester, 1 in Sheffield, 1 in Hull, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had steadily increased in the preceding nine weeks from 830 to 1374, further rose to 1389 at the end of last week; the admissions, which had ranged between 354 and 211 in the previous four weeks, were 272 last week. The Highgate Small-pox Hospital contained 72 patients on Saturday last, 23 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 291 and 305 in the preceding two weeks, were 302 last week, and exceeded the corrected weekly average by 15. The causes of 86, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Nottingham, Brighton, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Hull, Oldham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 23·4 and 21·2 per 1000 in the preceding two weeks, further declined to 20·5 in the week ending the 30th ult., and was 0·5 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·3 and 16·1 in Dundee and Aberdeen, to 22·9 in Paisley and 24·9 in Glasgow. The 500 deaths in the eight towns showed a further decline of 17 from the number returned in the previous two weeks, and included 27 which were referred to whooping-cough, 11 to measles, 10 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 4 to scarlet fever, 1 to diphtheria, and not one to small-pox; in all, 59 deaths resulted from these principal zymotic diseases, against 55, 79, and 67 in the preceding three weeks. These 59 deaths were equal to an annual rate of 2·4 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had declined in the previous five weeks from 30 to 22, rose again to 27 last week, of which 14 occurred in Glasgow, 5 in Edinburgh, and 3 in Dundee. The 11 deaths from measles also showed a further decline from recent weekly numbers, and included 9 in Glasgow. The deaths referred to "fever" and diarrhœa were not only fewer than those in recent weeks, but were below the average for the season; the 6 from "fever" included 3 in Edinburgh and 2 in Leith. All the 4 deaths from scarlet fever occurred in Glasgow, and the 1 fatal case of diphtheria in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 95 and 107 in the preceding two weeks, declined to 87 last week, and were 11 below the number returned in the corresponding week of last year. The causes of 68, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 35·0 and 31·2 per 1000 in the preceding two weeks, further declined to 25·7 in the week ending May 30th, and was lower than in any previous week of this year. During the first eight weeks of the current quarter the death-rate in the city averaged, however, no less than 31·7 per 1000, the mean rate during the same period not exceeding 20·6 in London and 18·3 in Edinburgh. The 174 deaths in Dublin last week showed a further decline of 37 from the high numbers in recent weeks, and included 13 which were referred to measles, 3 to "fever" (typhus, enteric, or simple), 3 to scarlet fever, 2 to whooping-cough, and not one either to small-pox, diphtheria, or diarrhœa. Thus, 21 deaths resulted from these principal zymotic diseases, against 34 and 33 in the preceding two weeks; these 21 deaths were equal to an annual rate of 3·1 per 1000, the rate from the same diseases last week being 3·1 in London and 2·3 in Edinburgh. The fatal cases of measles in Dublin, which had been 14 and 17 in the previous two weeks, declined to 13 last week. The deaths from "fever" and scarlet fever also showed a considerable decline from the numbers in the previous week. Five inquest cases and 6 deaths from violence were registered within the city; and 55, or nearly a third, of the deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable decline last week. The causes of 21, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Amongst the officers invalided from the Nile who embarked at Sawakin on the 30th ult. in the *Jumna* were Surgeons H. P. Birch and F. H. Treherne, of the Medical Staff.

War Office.—Army Medical Staff: Brigade Surgeon Jas. Henry Jeffcoat is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major John Wallace is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon John Mulrenan, M.D., has been placed upon temporary half-pay on account of ill-health; Surgeon-Major Edward Hopkins is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Alexander Allan, M.D., to be Brigade Surgeon, vice William Gerard Don, M.D., granted retired pay; Surgeon-Major James Ferguson is granted retired pay, with the honorary rank of Brigade Surgeon.

Admiralty.—The following appointments have been made:—Fleet Surgeon Thomas H. Knott, to the *Oregon*; Staff Surgeon Francis R. M. Loftie, to the *Leander*; Surgeons Leonard H. Kellett and James M'C. C. Martin, additional, to the *Duke of Wellington*; Surgeon Joseph W. Whelan, to the *Indus*.

India Office.—The Queen has approved of the following promotions among the Officers of the Staff Corps and Indian Military Services made by the Governments in India:—Surgeons David Wilkie, William Edward Bonsall Moynan, M.D., Denis Peter Macdonald, M.D., Oswald Baker, Frederick William Wright, of the Bengal Medical Establishment; Surgeons William Richard Browne, M.D., Mark Robinson, Arthur Henry Leapingwell, of the Madras Medical Establishment; and Surgeon Septimus Jesse Goldsmith, of the Bombay Medical Establishment—to be Surgeons-Major. Surgeon-Major Thomas Beaumont, M.D., of the Madras Medical Establishment, to be Brigade Surgeon.

Correspondence.

"Audi alteram partem."

THE LECTURES OF WILLIAM HARVEY.

To the Editor of THE LANCET.

SIR,—Early in February of the present year you were good enough to publish an appeal from me to the medical profession to assist in the reproduction of the original MS. notes of William Harvey's lectures, delivered in the Royal College of Physicians in and after 1616. The response to the appeal shows that the subject excites considerable interest, not only on both sides of the Atlantic, but at the Antipodes. The College of Physicians at its last comitia appointed a committee, consisting of Dr. Johnson, Dr. Payne, Dr. Norman Moore, Dr. Stone, and myself, to superintend the reproduction of the lectures in autotype facsimile, and has guaranteed the cost of 100 copies. A printed transcript will be furnished with each page of the autotype; the bad handwriting, the curious phraseology, and the abbreviations used by the great physiologist rendering some interpretation necessary. The lectures contain the first suggestions of Harvey's discovery of the circulation, so that this MS. may be regarded as the most interesting monument of natural science. The number of copies to be produced will be limited to 500. Messrs. Churchill have liberally undertaken to publish the work, without the usual commission, as soon as 350 copies are subscribed for. At least 200 more subscribers are required before the work can be put in hand. Dr. Weir Mitchell of Philadelphia, who already sends the names of ten subscribers and promises more, says, energetically, that "the thing must be done." We now hope, as the College of Physicians has extended its ægis over the undertaking, that with your further kind aid we may soon be enabled to say that "it will be done."

I beg to remain, Sir, faithfully yours,

Manchester-square, May 10th, 1885. EDWARD H. SIEVEKING.

P.S.—Any communications on the subject may be addressed to me, or to Messrs. Churchill, 11, New Burlington-street, London, W. I may add that the cost of each copy, including the transcript, and bound, will be £2 2*s.* to subscribers and £2 11*s.* 6*d.* after publication.

DEATH BY HANGING.

To the Editor of THE LANCET.

SIR,—Will you allow me to say, with reference to Dr. Kinkhead's interesting paper on this subject in your issues of April 11th and 18th, that I have seen four cases of death by hanging in soldiers, two of which were suicidal and two by sentence of a general court-martial, and that, so far as I can remember, the appearances of all these were very similar. There was the same pallor or lividity of the face, the same composed expression of the countenance, and the same absence of any trace of suffering or struggle on the part of all of them. The vertebræ were neither broken nor dislocated in either of the two suicides, and I believe they were not disturbed or injured in the case that was disposed of after this fashion under my own immediate observation. I was not near enough to the other to satisfy myself on this point one way or the other; and in neither was there, so far as my memory serves, any inquiry as to whether there had been any escape of fæces or semen. I have an impression, however, that discharges of this kind are neither invariable nor uniform after death from suspension of this kind, and a good deal will depend, I think, in this, as in other conditions of the subject, on the length of the rope and the age and weight of the body.

I have seen several natives of India despatched in this way, but have kept no notes of any of them; and the younger or the lighter the victim was, the lesser proportionately was the disfiguration produced in his remains afterwards. A more composed or less disfigured corpse than that of one of those here referred to (he was a small wiry man) I have never seen. In the other body, that of a larger, heavier, and older man, the face was somewhat bloated and puffy, while the conjunctivæ were slightly bloodshot; there was no post-mortem in either case. The bodies were, indeed, carried off for interment in a neighbouring cemetery as soon as the medical officer in charge had certified as to their identity and extinction of life. I do not know if the vertebræ were broken or not, but the rope used in both these cases was not, I think, nearly so long as that mentioned by Dr. Kinkead, and it is well known that those mild-mannered oily gentlemen, the Thugs of India,[1] who had "polished off" their thousands ere they were themselves "wiped out" by Colonel Sleeman and his followers, rarely if ever injured the vertebræ of their victims. Their *modus operandi* and simple implement—a Roumalor handkerchief—are described in Sleeman's "*Rambles and Recollections of a Bengal Officer*," as well as in the more accessible pages of the late Colonel Meadows Taylor, and I saw it myself *en apparence* at the hands of one of the initiated in the gaol at Lahore several years ago. It was nothing more than a species of *garrot*, but the old practitioner has acquired an aptitude for throwing or adjusting the "cloth" such as a Roman Retiarius might envy, and the rapidity with which he twisted the fatal knot more resembled a flash of lightning than anything else I can now remember.

As to the best, speediest, or most effectual method of *taking away human life now known to science* or civilisation, a word only must here suffice. The methods at present in use are—for we need say nothing about the old Jewish, Roman, or even mediæval practices—hanging, as above, and decapitations, as in France, &c.; and the methods suggested instead of these are narcosis, poison, and electricity. Of the first, which includes Richardson's lethal chamber, we need say nothing, for the process is neither certain, uniform, nor always expeditious, and its general enforcement would require such an amount of cultured intelligence, apparatus, and preparation as might not be always obtainable. Moreover, the process is too dramatic for this our sober atmosphere. As to the poison cup, it would appear to be as repellant to our notions of right as it undoubtedly is to our conceptions of religion and reality. The idea of forcing arsenic or opium, henbane or mandragora, *nolens volens*, down the throat of a murderer, is too odious, as well as too theatrical, to be even entertained; and the hari-kari of Japan savours too much of suicide to be compatible with the requirements of Christianity. We are therefore, or so long as we retain the penalty of capital punishment, reduced to a choice of evils—to, in a word, a choice between the rope of the common hangman of the period and the great discovery of him who was called, in derision, by his contemporaries, "the dancing-master of the frogs."

We are unfortunately but too familiar with the former, while our knowledge of the latter is even now very imperfect. So far, however, as it has been tried, accidentally or otherwise, it has proved itself by far the faster as well as the "certainer" slayer of the two. It slew its man at Manchester, as well as on board the *Livadia*, in a few minutes, while its victims at Hatfield and in the Health Exhibition succumbed at once, and it has thus proved itself as painless as it is undoubtedly instantaneous. All that is wanted is to get the victim to touch the conductors with both his hands, or, failing this, so to place him as that, by a simple mechanical arrangement, these latter may enclose or impinge on two exposed parts of his person. The rest follows quick as thought, as a matter of course, and the apparatus required for the generation of this fluid or force might be packed away in an ordinary travelling trunk. It is a pity the thing is not tried, if only by way of experiment, on some of our lower congeners, whence it might be transported in time to the higher regions of Newgate and the provinces. Had such an arrangement or apparatus been available a few months ago at Galway, we should not have had to deplore the horrid fate of poor Myles Joyce, neither would we have been subsequently shocked by the tragedies that were enacted at Liverpool and Exeter; and all the other dreadful paraphernalia and accessories of the hangman's craft might be dispensed with, or, at worst, so minimised by this process as to be imperceptible to all but the inevitable officials. I am, Sir, yours obediently,

---

[1] Sleeman says of these in a now utterly forgotten tract called "Ramaseeana, or the Vocabulary of the Thugs" (Calcutta, 1836, p. 27), that "no men cultivated with more care the esteem of their neighbours, or courted with more assiduity the good-will of all the constituted local authorities" than they did, and yet were they murderers on a scale such as the world has never yet witnessed in connexion with any other organisation, secret or otherwise. They were kind fathers, blameless husbands, and it is well known that they performed religious ablutions and other rites before the shrine of the Goddess Devée before they embarked upon any expedition. They scanned the face of the heavens in search of an [illegible] omen, and turned back in alarm from even [illegible]ure on sight of a jackal or other unpropitious [illegible] did, or rather do not, stand alone in these [illegible] have not hesitated to supplicate the Deity to sanction wrong or consecrate a crime; and, as Sleeman says elsewhere ("A Journey Through the Kingdom of Oude," vol. ii., p. [illegible]), "the facility with which men and women persuade themselves of a religious sanction for what they wish to do is not, unhappily, confined to any class or any creed."

Auriol-road, West Kensington, April 20th, 1885. Wm. Curran.

THE COMMERCIAL ASPECT OF THE TITLE OF "DOCTOR."

To the Editor of The Lancet.

Sir,—"The battle of the shops," as Sir Dominic Corrigan called the competition of the medical examining bodies, has had many serious consequences, but none more so than the proposal on behalf of the two Royal Colleges of England to ask for legal powers to give the title of "Doctor" to all who pass their lowest examinations. I cannot yet believe that the two Colleges will really take this step. No doubt, as you say, the title of "Doctor" has a certain commercial value. You might have added that there is a certain and very conspicuous commercial value in the power of selling this title, which has led other Corporations into temptation to use it commercially with the most disastrous consequences to their reputation. It is said that one Royal College made in one year £10,000 by this merchandise. The Royal Colleges of England have hitherto refused to have anything to do with a questionable title, whatever its commercial advantage. But now even such men as Mr. Durham and Mr. Savory are gravely proposing to try to acquire the *legal* right to grant a title, the value of which to the possessor will be in the proportion in which it conveys a false impression to the public. It is scarcely likely that Parliament will grant a title hitherto reserved for graduates of Universities, and the divorce of which from medical degrees would be a most serious discouragement to higher medical education as well a great injustice to medical graduates who to get their degrees have gone through the curriculum of a university, and through the examinations of the university, generally *in addition to* going through the examinations of the corporations. The statement that the ordeal for getting a Scotch degree is not more severe than that for gaining the qualifications of the English colleges is not relevant. To repeat it after the refutations it has received is scarcely polite. But even if it were true, it points, as so many other facts do, to another conclusion—viz., the necessity for creating a strong Medical Council that can and will enforce distinctions between examinations for mere qualifications and examinations for degrees. It is surely desirable that the English Colleges should pause before going to Parliament with a prayer so unworthy of their position and record. "Brummagem" titles are beginning to die out, and their possessors to be ashamed of them. But if they are to have a fresh lease, it surely ought not to be at the instance and prayer of the English Colleges. These Colleges never needed less the "commercial" advantage of such a trade as is understood to have been so lucrative elsewhere. I see by the latest returns that the membership of the Royal College of Surgeons of England last year, with all its legal defectiveness as a diploma, was acquired by no less than 562 persons, a number far above the reach of any other body, corporation, or university in the kingdom. The Royal College of Physicians of London exceeded itself and all other fairly comparable bodies. And now, forsooth, these honest and high-minded bodies are asked to come down to a false title business, and to go whining to Parliament representing the impending ruin of London schools. The London Schools will be very badly advised if they encourage this inadequate and undignified proposal. I admit, as a Scotch graduate, the London schools have a grievance which wants immediate redress. The London teachers want consolidation of London schools and association with a Teaching University. Let them take a leaf out of the book of Scotch professors. Let them besiege Parliament—as the Scotch professors do with so much effect, when need so requires—till the crying defect of this metropolis (a practical working university) is supplied. Then the medical schools of London will be filled, the Degrees of London will exceed those of other portions of the Empire at once in number and in value, and the high example of the London corporations, everywhere felt if not everywhere followed, will continue to preserve the profession from low purposes and false pretensions and sham titles.

I am, Sir, your obedient servant,

June 1st, 1885. M.D.

To the Editor of The Lancet.

Sir,—I do not see that your correspondent, Mr. Wright, has much legitimate cause for complaint. Doubtless, a certain commercial value generally appertains to the title of "Doctor" in Medicine. And what should qualify a man for this distinction? Not so much, I should say, two or three additional subjects in his Preliminary Arts Examination, as a sound and efficient course of medical and surgical teaching, with due *opportunities for practical* work and clinical observation, such course being terminated and the quality of the work done guaranteed, as far as possible, by *correspondingly efficient examinations.* Now, I have no doubt that Mr. Wright and his fellow graduates have had the advantages of this kind of curriculum; but I am at a loss to see how the successful candidate for the double qualification of L.R.C.P., M.R.C.S. Lond., differs from them in this respect. The medical course in each case embraces the same period of four years; with very trifling exceptions the subjects of study are equally ample, and the student at the great London schools has the advantage of the most brilliant teaching—that of men who are the *crême de la crême* of their profession—combined with the unrivalled opportunities for clinical and surgical work which a great metropolis alone affords. Respecting the "considerable extra expense" necessary to obtain a Scotch degree, I need say little. I think that all who have sought information on this point will consider that the extra cost exists only in the imagination of your correspondent. In my opinion, and probably many will agree with me, the objection to the proposed action of the Colleges has sprung from quite the wrong quarter. The injustice done, if any, by conferring the degree as suggested, would be done to men who have gone through the severe strain, the long course, and the greatly increased expense necessary to obtain a degree like that of London University. These would have real ground for objecting to the new scheme; but I think that they would have almost as much cause to complain that men like Mr. Wright and his compeers, who have experienced so comparatively easy a curriculum, should have the right with them to the *title* of M.D. According to Mr. Wright's argument, "ought not a still higher title to be granted" to those who have in reality obtained a so much higher qualification? It is, however, a very difficult matter to be entirely just to all; the most crying evils should first obtain a remedy, and it is certainly time that something should be done to protect the London students from being in any way overshadowed by those licentiates of the Scotch corporations who, with much inferior qualifications, arrogate to themselves the title of "*Doctor.*" If *some* change of the kind proposed is not brought about, probably the tendency, already marked, of students to go to those universities where a degree may be obtained at no toil and expense in excess of that required in obtaining the double London qualification, *will be* very greatly increased in the future.

I am, Sir, yours faithfully,

Westminster Hospital, June 1st, 1885. Wm. Theodore Rayne.

ON THE CONTAGIOUS DISEASES ACTS.

To the Editor of The Lancet.

Sir,—It seems to be admitted by all writers of the history of syphilis that at times the disease has taken quite an epidemic character, and really in England we seem as if endeavouring to revive these periods by the gross neglect of the most simple means of at least trying to arrest somewhat the triumphant course of the malady. There seems a tendency to mix up morality with science. Would it not be advantageous to separate them and speak of each in its proper place?—for it is difficult to treat of the prevention of venereal disease if at the same time one has to assume a high moral standard. Taking a broad view of the matter, would it not be better for those in authority to be practical and try to mitigate by prudent measures as much as possible the ills that so often accompany immorality? To begin with, one of the most simple and most easily applied means of checking their spread is the enforcement of the Contagious Diseases Acts in garrison towns and large seaports. Why this is no longer done is a mystery to most sensible and thinking men. While visiting the Royal naval sick quarters at Portland some time ago, my cousin, Mr. E. V. de Méric, Staff-Surgeon R.N., who was then in charge, kindly took me round, and on my expressing surprise that four-fifths of the beds were occupied by venereal cases, he assured me that it had been so ever since the Contagious Diseases Acts no longer gave some sort of protection to the men. If this be so in a small place like the Royal naval sick quarters at Portland, what must it be in large seaports such as Portsmouth or Plymouth? I have heard, too, that at some of our seaports, when a transport is expected, many women in hospital affected with venereal disease leave the institution in order to go and meet the ship; and what can the surgeons do? Of course, nothing. The law has decided that these women should be free from the hospital surveillance to infect these poor fellows, only just arrived in their native land, with diseases which they would take to their wives and to the towns or villages which contain their homes. With regard to the argument that is often brought forward against the compulsory detention of prostitutes, that it would be interfering with the "liberty of the subject," it seems to me the same law which deals with maniacs or small-pox patients might come into force to prevent a woman with a venereal complaint carrying devastation freely in her path without let or hindrance; excepting, of course, if the law take the high moral instead of the practical and scientific ground.

A most able and straightforward annotation in THE LANCET of Feb. 17th, 1883, after discussing the decision of the Select Committee of the House of Commons on the Contagious Diseases Act, August, 1882, not to recommend its extension, contains the following words:—"Having established the great physical and moral gain effected by these Acts, the logical outcome of the recent inquiry would be to recommend their immediate extension; but this the committee have hesitated to do in deference to the position and character of some of those who have opposed them." Now, there seems to me scarcely a doubt that if the entire question were explained simply and without any artificial varnish to those who so strenuously oppose the Contagious Diseases Acts, were it shown to them more particularly from a *medical* point of view, they would at once cease their opposition, and be the first to advocate not only the feeble way these Acts have been applied in this country, but also their extension.

The compulsory examination of prostitutes in our garrison towns and large seaports seems to me a subject that so palpably carries its own weight as only to require the energetic support of the naval and military surgeons to come again into full force. The great difficulty arises when we ask the question: Can nothing be done for London? Can anyone answer satisfactorily such a query? One feels a vague sense of helplessness in approaching it, and yet something ought to be done; the prostitution which is so rife in this vast metropolis is absolutely under no control whatever, particularly in a sanitary point of view, and it is perfectly certain that were better sanitary measures employed there would be a marked amelioration, both morally and socially, and our streets would no longer be made hideous by the scenes which now take place every night in some of the principal thoroughfares. Therefore the very first thing required in London is more hospital accommodation for venereal disease in women. Of course we have the female Lock, for which I believe funds are much needed, and all praise is naturally due to those general hospitals that have a venereal ward, although, considering the population of London, these means of receiving as in-patients women affected with syphilis bring to mind a drop in the ocean. Now, there is no use whatever to humanity in general for a prostitute to attend a hospital as an out-patient; because, as she must procure money to live, she continues her calling during the whole time of her treatment, and not only retards her own recovery, but sows the disease broadcast every night. No! What is wanted in our metropolis is a large hospital where these women would be received as in-patients and kept till at least all external signs of the disease had disappeared. Such an institution could not be supported entirely by voluntary contributions, but would have to be subsidised by the Government. For those who regard the whole question from only its moral side, it may be pointed out how many women might be reclaimed altogether from a vitiated life through the influence of the quiet and good surroundings of this institution, which might be in direct communication with the reformatories and homes for fallen women of which we hear so much. Perhaps many will say that the very women for whose treatment such a hospital would be intended would not voluntarily present themselves as patients, but I am sure every surgeon who sees out-patients in a London hospital will bear witness that the large percentage of women affected with venereal disease would only be too glad to become in-patients in a properly organised institution, and to go there on the first suspicion of the affection; so we could replace the words "compulsory examination" by those of "voluntary examination." What a boon too for medical science, as the profession would then be enabled to study more completely venereal disease in the female; at the present time there are very few chances in England of making any researches on the subject, and the opportunities for students to see a woman properly examined and the case scientifically explained are indeed few and far between. The good effects of this scheme would only be a question of time, and the benefits derived hereafter by a whole nation would, I should imagine, fully justify the expenditure of public money for its trial. But the first and most important thing is to bring the Contagious Diseases Acts into full force at our garrison towns and large seaports, which would after a time diminish by *contre-coup* the amount of venereal disease in London, being materially assisted by the palliative means of a large venereal hospital in the metropolis itself, but without which the good effects of the London institution would in a great degree be minimised.

I am, Sir, your obedient servant,
H. DE MÉRIC, M.R.C.S.,
Surgeon to the French Hospital, London.
Duke-street, S.W., May, 1885.

AURAL EXOSTOSES.

To the Editor of THE LANCET.

SIR,—In an article on "Aural Exostoses" in THE LANCET of the 30th ult., by Mr. Field, he mentions his first case as having been operated upon in 1877, and that the instrument used was a dentist's drill. May I be allowed to say that in a paper on this matter in THE LANCET of Jan. 22nd, 1876 (in which the local origin of these growths was strongly insisted on), I stated that since 1874 the method I had employed was as follows:—"It consists in grinding the bone away; and the most satisfactory appliance for this purpose I find to be the drill which is in common use among dentists. The variety of steel instruments which can be fixed to this, and the perfect command with which they can be directed, render this an especially convenient instrument."

I am, Sir, yours faithfully,
Savile-row, June, 1885. W. B. DALBY.

LIVERPOOL.

THE INFECTIOUS DISEASES HOSPITAL QUESTION.

AT an adjourned meeting of the City Council on the 20th ult., the report of the special committee appointed to consider the question of the proposed hospital for infectious diseases was read. It embodied the following recommendations:—"1. That the Council be recommended to obtain a plot of land of sufficient extent to afford hospital accommodation if required for 650 patients suffering from dangerous infectious diseases. 2. That in the opinion of this committee the requisite accommodation can be provided upon either the Green-lane site or the Edge-lane site. 3. That the Council be recommended to take the requisite steps to obtain a loan of £100,000 for the purpose of defraying the cost of such hospital accommodation and site, and that the Local Government Board be requested to cause an inquiry to be instituted as to the proposed sites, and to inform the Council which of the two is, in their opinion, the preferable one." Mr. Robert Hamilton, F.R.C.S., who had been the chairman of the special committee, regretted that he felt compelled to oppose these recommendations, and moved the following amendment:—"That the report be approved except paragraphs 1, 2, and 3; that two sites be secured at the north and south ends of the town respectively for two small district hospitals of eighty beds each; that a plot of land be secured within easy distance of the city on which to erect a convalescent home for 180 patients, thus making provision for 340 cases; and that the requisite steps be taken for obtaining a loan of £100,000 for the purpose of defraying the cost of such hospital accommodation." This amendment was carried by thirty-two to nine. The great difficulty will be to find sites sufficiently accessible to be suitable for their purpose, and also sufficiently far off from inhabited houses to avoid incurring the opposition of their owners or occupiers.

A RIDICULOUS SUPPOSITION.

The county coroner for South-west Lancashire and his deputy have recently held numerous inquests on the bodies of suicides, hanging being the mode most frequently adopted. An absurd idea prevails in and about the neighbourhood of St. Helens, where some of these cases have occurred, that it is improper to cut down the body until the police have arrived. Some months ago the deputy coroner was informed by a police inspector that in more than one case life might have probably been saved, but for the fact that the bodies had not been cut down until the police arrived, a proceeding which involved much delay, as the cases were at a considerable distance from the police station. On this occasion the deputy coroner asked the deceased's brother why he did not at once cut his brother down, and was informed that he thought it would be wrong to do it except in the presence of a police officer. When asked if he would wait for the police before rescuing any one from drowning he was silent. The deputy coroner expressed himself very strongly, and his remarks would appear to have done good; since at a recent inquest it appeared that one of the witnesses had promptly cut down the deceased in spite of the remonstrances of others present, who wished him to wait for the police.

THE NORTHERN HOSPITAL AMBULANCE.

The horse ambulance instituted in connexion with the Northern Hospital has proved so valuable as to have become a generally acknowledged necessity. The hospital is in telegraphic and telephonic communication with the central police office and district bridewells, and by arrangement ambulance messages have precedence over all others. It is greatly to be desired that all the local hospitals should each have its own ambulance, and arrangements could be easily made by means of which each hospital could have its own district. By this means accidents and urgent cases could be safely taken immediately to the nearest hospital.

THE STANLEY HOSPITAL.

When the Northern Hospital was erected, about forty years ago, it stood not far from what was then the extreme northern boundary of Liverpool, and was therefore appropriately named. Since then the borough has extended so enormously that the present northern hospital occupies a position which would be more appropriately described as central, while the Stanley Hospital, established in 1867, is, geographically speaking, the northern hospital. This hospital has recently been enlarged, a proceeding which had become necessary in consequence of the great and daily increasing number of accidents and other cases demanding admission. But before the new wings can be utilised a sum of £3000 must be raised; and to aid this very laudable object the Mayor (Mr. David Radcliffe) has opened a subscription list at the Town Hall. The hospital is doing a most excellent work; the number of patients both in and out is daily increasing; and though the times are not very favourable for such appeals, it is hoped that the sum required, which will only free the hospital from debt, will be shortly raised.

THE HOSPITAL SATURDAY FUND.

Upwards of £2500 has been raised this year by means of the Hospital Saturday boxes, cages, &c. This is a decided improvement both actually and comparatively, though scarcely such as might be expected considering the great and perfectly voluntary labours of the honorary treasurer and secretaries, aided this year by the Working Men's Committee. It is also in painful contrast to the sum of £6000 raised by the Birmingham working men for their hospitals.

A BOON TO TRAVELLERS.

Passengers to Liverpool by the London and North-Western Railway had, until recently, to undergo a terrible ordeal before reaching the terminus, in the tunnel which ran under the city from Edge-hill to Lime-street. The atmosphere was so impregnated with smoke, steam, gas, and other impurities, as to try severely the strongest chests at times, and to make it impossible for those with delicate chests to incur so serious a risk. This has now been removed by the gradual conversion of the tunnel into a cutting at an enormous cost, only a very small portion of it being left. This will conduce greatly to the comfort of the thousands of persons who are compelled to use this line, as well as to the improved health of the railway *employés*.

Liverpool, June 1st.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE SANITARY STATE OF NEWCASTLE.

THE twelfth annual report of our medical officer of health, Mr. H. E. Armstrong, has just been issued, and it is a searching analysis of the facts presenting themselves in every section of the important department over which Mr. Armstrong presides. The twelve months' sanitary work in this city, of which the report is a record, has been an important one. During the period in question a sanitary house-to-house inspection has been carried out. A serious epidemic of scarlet fever rose and declined; the small-pox, which attained its height in 1883, gradually faded away. The first premonitory symptoms of the pest of measles, which is now scourging our city so violently, became visible. Unfortunately the disease of measles does not figure in the schedule of the local Act by which notification to the sanitary authority is prescribed. The experience of the epidemic at present prevailing in the north of England shows that the complaint may assume a malignant form, fairly entitling it to come within the scope of municipal notification. Mr. Armstrong, as the result of a summary of an immense amount of statistics, says that 70 per cent. of the infectious diseases occurred in tenemented property, of which infected premises nearly three-fourths consisted of houses of one or two rooms each; that in upwards of 70 per cent. of the infected households the sick-rooms were not at all isolated from the rest of the house; that in 50 per cent. of such households no precautions to prevent the spread of infection were being taken at the time of the inquiry; that in only a small proportion of the cases (in scarlet fever barely 2 per cent.) was removal to hospital consented to by the patient or his friends; that a large amount of trade and processes of trade are carried on in and in immediate connexion with, infected premises, and at other places attended by persons residing upon infected premises, by all of which means infection is liable to be communicated to the public. Mr. Armstrong holds that this state of things affords proof of the necessity of ample hospital accommodation for infectious diseases; compulsory power to remove to hospital all cases of infectious diseases in tenemented dwellings, and special provision to deal with infected business premises, and to prohibit the attendance at business of *employés* residing in infected houses where means of isolation are insufficient. Amongst the curiosities of the report may be mentioned the discovery in a body, taken for dissection to the Medical College here, of the disease trichinosis, and it is believed to be the first observed in this city. Means were taken to trace the source of infection in this case, but without effect; numerous samples of pork, ham, and bacon were carefully collected from the neighbourhood in which the subject had lived, and subjected to close microscopical examination, but no trichina spiralis was found.

WHITLEY CONVALESCENT HOME.

At the late annual meeting held at the Home at Whitley, Dr. Philipson, in presenting the medical report, stated that 1336 cases had been treated; of these 1063 were medical and 273 surgical cases, and taking the whole, 1298 received benefit, or over 97 per cent. The subject of providing a children's ward had come under consideration by the committee, and overtures had been made to the Newcastle Children's Hospital, and to the trustees of the Sunderland Victoria Hall fund; nothing of a practical form had resulted.

THE LATE MR. ROUTLEDGE.

I should mention the death on May 18th of a gentleman who, although not a member of our profession, yet was well known to a large medical circle. I allude to Mr. William Routledge, dentist, of this city; he was for many years assistant to the late Mr. Sheffield of Exeter, and while at Exeter he was one of the most active members of the Exeter Literary and Philosophical Society, and held the office of treasurer for many years. So careful was he of the Society's funds, that he was named by his colleagues "Joe Hume." When he left Exeter for Newcastle the profession and the Society entertained him at a banquet and presented him with a substantial testimonial. While in Newcastle his practice as a dentist was very successful, and he enjoyed in a very great degree the confidence of our profession. Mr. Routledge, who was in his fifty-fourth year at the time of his death, was of a very kindly nature, and possessed of refined tastes. His knowledge of botany was extensive, and he has left here a very large number of scientific and general friends to regret their loss.

THE VOLUNTEER REVIEW AT GOSFORTH.

A new feature in the Volunteer review and sham fight to-day was the formation of complete bearer companies in the ambulance department, and their march past. This created much interest in the field, and the arrangements were considered very complete and satisfactory, Surgeon-Major R. F. Cook being the principal medical officer in charge.

HARROGATE BATHS AND SPAS.

Dr. Myrtle of Harrogate, who has been visiting continental spas having close affinities in composition and curative properties to those of Harrogate, writes to a local paper to say that he finds Harrogate no way behind in springs and baths to the towns he had visited, but that Harrogate possesses immense advantages in having so many spas so dissimilar in properties within a narrow circle, while some of the continental spas are separated by hundreds of miles. He points out, however, that Harrogate lacks in skilled attendants, and that at many of the continental places the patient has merely to put his dressing-gown and slippers on and walk directly to his bath already prepared for him; after it, a few steps replace him in bed. This arrangement is of immense advantage to a certain class of patients. But upon the whole, *he is* prepared to show that Harrogate offers to the great majority of invalids advantages not to be obtained elsewhere.

Newcastle-on-Tyne, May 25th.

IRELAND.

(*From our own Correspondent.*)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual election of office-bearers was held last Monday, when Dr. Cameron, Vice-President, was promoted to the Presidency, and Mr. William Stokes, Professor of Surgery in the College, was elected Vice-President without opposition. For Council, twenty-one candidates competed for nineteen places, with the result that all the outgoing members were re-elected; and Mr. William Colles was re-elected Secretary to the College, a post he has now occupied for many years. This was the first time the election of office-bearers took place by means of voting-papers forwarded through the post or otherwise, so as to permit provincial Fellows to vote *in absentia*. The result, however, did not come up to general expectation, as only 143 votes were recorded out of a large constituency. The election of Dr. Cameron as President of the College requires a few words. A non-practising surgeon, in the person of Dr. Cameron, has been selected for the first time on record by the Fellows to the highest position the College can confer. It was, however, for other reasons that the selection was made. Dr. Cameron is the efficient medical officer of health for Dublin, and is one of the highest authorities on sanitary science. Independently of this, he is an excellent microscopist, a good pathologist, and by his position and talents is well qualified to hold the honourable position to which he has been unanimously elected. I may add that there is not in the city of Dublin a more general favourite among his professional brethren, or one more highly esteemed by the public, than Dr. Cameron. The election of examiners took place last week, when, consequent on the newly acquired Charter, several additional vacancies occurred. In view of the well-known conservative tendencies of the Council, it was not a matter of much surprise to learn that all the outgoing examiners, with the solitary exception of one in midwifery, had been re-elected. The election of Dr. Mapother as examiner in physiology and histology will no doubt give general satisfaction. The rule has been rigorously carried out that not more than two examiners belonging to any medical school or hospital shall be elected. There were vacancies for two examiners in the department of physics, chemistry, and medical jurisprudence, but only one was elected. At a recent meeting of the Council certain arrangements were adopted for the oral examinations, and as a result no teacher will be permitted to put questions to a candidate from his own school, nor will examiners who are teachers in the same school be allowed to examine at the same table; while in practical examinations, such as dissections, operative surgery, and clinical examinations, the same rules will be observed as in the oral. The following is the complete list of the newly elected examiners:—Anatomy and Comparative Anatomy: B. G. MacDowel, L. H. Ormsby, E. Stoker, R. L. Swan. Surgery and Surgical Pathology: C. B. Ball, H. G. Croly, E. S. O'Grady, W. Thomson. Medicine and Therapeutics: M. Boyd, R. Hayes. Materia Medica, Pharmacy, and Botany: W. Frazer, H. Minchin. Physiology and Histology: P. S. Abraham, E. D. Mapother. Physics, Chemistry, and Medical Jurisprudence: J. D. Pratt. Midwifery: J. J. Cranny, S. Mason. Ophthalmology: A. Benson, H. Swanzy. Diploma in Midwifery: Henry Croly, S. Mason, W. Roe. General Education: F. Davys, R. Morton, H. J. Tweedy.

ROYAL UNIVERSITY OF IRELAND.

At a recent meeting of the Senate, Marcus Hartog, D.Sc., Professor of Natural History, Queen's College, Cork, was elected a Fellow in the Department of the Natural Sciences, subject to the usual conditions. The Senate, at the same meeting, also resolved that credit shall not be allowed at the Second Examination in Medicine for Chemistry to any candidate who shall have passed in that subject at any examination in the Faculty of Arts after 1885. A meeting of Convocation was summoned to be held last week for the election of a representative on the Senate, and for the consideration of various notices of motion dealing with the constitution of the University. The meeting, however, fell through, one additional member being necessary to form a quorum; but it is understood that a requisition will be presented to the Senate to call another meeting. A similar misfortune occurred, if I mistake not, last year; and the circumstance is to be deplored, as on this occasion motions of considerable importance were to have been moved by Dr. Knight, Mr. Farrelly, Mr. Maguire, F.T.C.D., and Mr. Johnstone Stoney.

BELFAST ROYAL HOSPITAL.

For the past quarter there has been a falling-off in the income as compared with last year, and a decrease from Sunday collections amounting to £160. It is scarcely credible that the total amount obtained in a wealthy place like Belfast from Hospital Sunday only reached £300. There must be some reason for such apparent apathy and want of sympathy towards so valuable an institution as the Belfast Royal Hospital. The working classes, it is gratifying to state, show their appreciation of the work done by the hospital in the constantly increasing amount of their contributions; but their employers and the wealthy members of the community do not subscribe as they should. Certainly on April 30th there was a balance in favour of the hospital, but it is not improbable that before the termination of the present quarter the institution may find itself largely in debt.

Dr. O'Farrell, J.P., of Boyle, who was lately appointed a Local Government Board inspector, has been presented by his numerous friends with an address, a valuable service of plate, and a gold watch, on his departure from that town.

Dublin, June 2nd.

THE HOSPITALS ASSOCIATION.—Mr. J. L. Clifford-Smith has resigned the office of Honorary Secretary of the above Association.

PARIS.

(*From our Paris Correspondent.*)

DEATH OF DR. N. GUÉNEAU DE MUSSY.

I regret to have to report the death of Dr. Noël Guéneau de Mussy, which took place yesterday morning at his residence in Paris. He had been ailing for some time, and spent the winter in the south of France, whence he returned only on Thursday last, somewhat improved in health. He intended to resume his practice, which was very extensive, but his condition became aggravated and he expired rather unexpectedly. Dr. Guéneau de Mussy was a well-known and much-esteemed physician, and his death will be a great loss not only to the French, but also to the English and American residents of Paris. He was seventy-two years of age. He took his degree in 1839, was an Agrégé of the Faculty of Paris, Member of the Academy of Medicine, and for many years Physician to the Hôtel Dieu.

THE FUNERAL OF VICTOR HUGO.

That accidents should occur in such a great concourse of people as that brought together to witness the funeral procession of Victor Hugo was inevitable; but the number was few in proportion to the densely packed multitude that thronged the thoroughfares. There were several broken arms and legs caused by falling from trees and platforms, &c., which were erected for the occasion. There were also some cases of fainting and insolation, principally among the soldiers; this is not to be wondered at, as the weather was rather sultry, which added considerably to the fatigue of having to stand so many hours without food or drink.

The Cardinal Archbishop of Paris, whose health had much improved, has had a relapse of his bronchial affection, and his condition, which is rather critical owing to his advanced age, is causing great anxiety to his friends.

Paris, June 3rd.

VIENNA.

(*From our own Correspondent.*)

SMALL-POX IN VIENNA.

The epidemic of small-pox has been severe. In Vienna proper, strict prophylactic measures have been taken to prevent its introduction. During the month of March 414 persons were attacked by the disease in the suburbs and 282 in the city. In one week 82 persons fell ill in Vienna, of whom 20 died, 124 cases occurring in the suburbs. In the week following 76 cases of small-pox were recorded in the city, 14 ending fatally; in the suburbs 120 cases were registered. The population of Vienna amounts to 748,889; that of the suburbs to 321,564.

AMAUROSIS AFTER PARTURITION.

The following interesting case was observed by Dr. L. Königstein, in the clinique of Professor Spaeth. A woman, aged twenty-eight, was delivered of a seven-months' child on Aug. 29th, 1884. The course of the pregnancy and delivery was normal. Shortly after the expulsion of the placenta the patient fell asleep, and when she awoke, after the lapse of three hours, she was totally blind. Dr. Königstein, on examining her next day, found outwardly nothing abnormal. The pupils were enlarged almost *ad maximum*, their reaction on light and shade was very weak, and the patient could scarcely distinguish light from darkness. The ophthalmoscope showed striking paleness of the papilla and narrowing of the arteries. No medication was employed. By Aug. 31st the patient's vision had improved considerably. She could perceive movements of the hand at a distance of one metre. The field of vision was limited. No ophthalmoscopic change was observed. On Sept. 1st distinct reaction of the pupils was present. The field of vision was free. The next day the acuity of perception was normal, the arteries being somewhat distended. After the lapse of another week all was normal. The blindness consequently was caused by retinal ischæmia, which occurs but rarely in childbed, as in general uræmic amaurosis after eclampsia, or amaurosis after severe hæmorrhage occurs; but in this case the urine contained no albumen, and free hæmorrhage did not take place. Only one case similar to the above is known—namely, that observed by Weber in St. Petersburg, and published in the *Berlin. Klinische Wochenschrift* in 1873.

THE SYPHILIS BACILLUS.

Dr. S. Lustgarten recently lectured in the I. a. R. Society of Physicians on his researches on the syphilis bacillus; his statement being corroborated and somewhat widened by the experiences of Dr. Julius Fürsh and Dr. Julius Mannaberg, from the Vienna Dermatological Clinique, in connexion with a recent case of sclerosis. The sclerosis contained a large number of bacilli as it were in the form of nids.

THE APPLICATION OF PHOSPHORUS IN CASES OF RACHITIS.

Some years ago Wegner described the changes of the bones of animals caused by the ingestion of phosphorus, and hinted that this drug may perhaps play a *rôle* in the therapeutics of rachitis. Kassowitz, in Vienna, took up Wegner's idea, and not only repeated the experiments with animals, but also applied this remedy to rachitic children. As he stated at the meeting of Natural Philosophers in Freiburg, in 1883, he obtained excellent results with this remedy. Last year in Magdeburg he was already able to announce with greater certainty that phosphorus, if taken in doses of half a milligramme per diem, removed all the symptoms of rachitis. Many physicians experienced in children's diseases agreed with Kassowitz; but opponents of the treatment also arose. Baginsky, in Berlin, applying phosphorus for rachitis, observed only in 8 cases out of 72 a slight improvement; in 4 cases even a deterioration. Lorey, in Frankfort-on-Main, had 25 cases, in 7 of which the application of phosphorus produced a good effect, and in 18 the success was doubtful or altogether wanting. Professor Weiss, in Prague, had in 7 cases a negative result, and in only a single instance a positive one. Schwechten, in Berlin, observed out of 41 cases 4 recoveries and 21 improvements; 11 times phosphorus produced no effect, and 5 times it caused deterioration. Professor Monti, in Vienna, is of the same opinion.

EXPERIMENTS WITH RHODANE POTASSIUM.

The saliva contains, as is well known, rhodane potassium, and the urine combinations of it. As only little is known about its physiological and toxic qualities, Dr. Paschkis, from Professor Stricker's laboratory, made experiments with it on animals. An application of rhodane natrium or rhodane hydracid increases the reflex irritability; if applied in small quantities it causes tetanus, which is more lasting than that caused by strychnine. Rhodane potassium increases the blood pressure and irritates the terminal prolongations of the vagus in the heart. A solution of it, if dropped on the heart of the frog, produces stasis of the organ, lasting up to fifteen seconds. Paschkis employed the soda, and not the potassium salt, to exclude the effect of the potassium on the heart.

THE VIENNA UNIVERSITY.

For the forthcoming summer term 195 theoretical lectures and practical demonstrations are announced in the Faculty of Medicine, to be delivered by 121 professors, "docenten," and assistants. In the past winter term 2291 ordinary (of whom 873 were from Hungary) and 164 extraordinary students matriculated in the Faculty of Medicine. In the whole of the Faculties the number of ordinary students amounted to 5076, that of extraordinary students to 765.

Obituary.

JOHN MORE YOUNG, M.A., M.B., C.M. Glas., &c.

We have just received notice from India of the sudden death of Surgeon John More Young, I.M.D., from hydrophobia. It seems that about two months and a half before the melancholy event, while caressing a little sick dog (belonging to a brother officer), it licked his hand, on which, unfortunately, there was an open suppurating sore. The hand swelled and was painful for a day or two, but no more was thought about the matter, although the pet dog died from rabies, the result of a bite from a mad dog. Mr. Young, however, was not left long in forgetfulness, for in about two months he began to complain of great lassitude, weakness, and prostration, with dysenteric diarrhœa. About April 25th—i.e., three days before death (for up to this time he had continued his hospital duties)—intense neuralgic pains came on in his neck, which on the 26th gave place to spasms of a terrible character, and then the truth was forced upon him and all *his friends and attendants that he* was the victim of hydrophobia. He had all the well-known symptoms of that dreadful and incurable disease, and died on the 28th in the arms of Captain Reid, one of his brother officers.

Mr. Young was the most distinguished student of his year, and passed into Netley at the head of the list. In passing out of Netley, he still further distinguished himself by taking all the first prizes. He joined the I.M.D. only two years ago, and was stationed at Gorakhpore, and as a testimony to his genial, brilliant, and lovable character it may be mentioned that his brother officers are about to place a memorial tombstone over his grave.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen passed the first part of the Professional Examination (Anatomy and Physiology) for the Fellowship at a meeting of the Board of Examiners on the 28th ult.:—

Henry W. Drew, Guy's; Felix C. Vinrace, London and Birmingham; Sydney E. Holden, University College; Henry G. Lys, London; Frederic W. E. Green and Frederick W. Andrewes, St. Bartholomew's; William F. Brook, St. Thomas's.

(Candidates referred, 13.)

Passed on the 29th ult.:—

John O. Tunstall, University College; James J. Clarke, St. Mary's; Harold K. Roper, Guy's; Jasper J. Garmany, Bellevue Medical College, New York.

(Candidates referred, 8.)

The following gentlemen, having passed all the necessary examinations for the diploma, were admitted Members of the College on the 1st inst.:—

Dearden, William Francis, L.S.A., Portland House, Bolton.
Howe, Joseph Duncan, L.S.A., Stockport-road, Manchester.
Stericker, Frederick Walter, M.B. Cantab., Goodlands, Jersey.
Kidd, Hugh Cameron, L.R.C.P. Lond., Leamington-road Villas.
Carpenter, George Alfred, L.S.A., Fentiman-road, Clapham-road.

Professor John Wood, F.R.S., will commence a course of three lectures on "Hernia and its Radical Cure" on Monday, the 8th inst., at 4 o'clock precisely.

ROYAL UNIVERSITY OF IRELAND.—The following degrees were conferred at a meeting held on May 27th:—

DEGREE OF M.D.

Alexander, S., Queen's Coll., Belfast.
Barron, J., „ „
Burrows, J. R., „ „
Corry, Alex., „ „
Crawford, G. B., „ „
Curtin, M. H., „ „
Dwyer, T. W., „ Cork.
English, Robert, „ „
Foott, G. H., „ Belfast.
Foott, R. E., „ Cork.
Hannigan, M. H., Catholic Univ. Sch. of Medicine.
Hawkins, W. R., Queen's Coll., Cork.
Hennessy, Daniel, „ „
Loughrey, W. J., „ Belfast.
McAleer, J., Queen's Coll., Galway, and Catholic Univ. Sch. of Med.
McCarthy, M., Queen's Coll., Cork.
McWha, W. R., Queen's Coll., Belfast.
Marks, G. F. H., Queen's Coll., Cork.
Meenan, J., Carmichael Coll. Med.
Musgrave, J., Queen's Coll., Cork.
Nagle, James J., „ „
O'Brien, J. J., „ „
Petticrew, R., „ Belfast.
Pooler, Edward L., „ „
Ryan, J., Queen's Coll., Galway, and Catholic Univ. Sch. Med.
Savage, J. M., Queen's Coll., Belfast.
Sexton, W., „ Galway.
Sharpe, J. H., Carmichael Sch. Med.
Smyth, N., Queen's Coll., Belfast.
Thomson, Robert, „ „
Tresilian, F. J., „ Cork.
Whitty, M. J., Queen's Coll., Cork, and Catholic Univ. Sch. Med.
Wilson, S., Queen's Coll., Belfast.

DEGREE OF M.B.

Griffin, R. M., Ledwich Sch. Med.
O'Byrne, James P., Catholic Univ. Sch. Med.
Walsh, James J., Royal College of Surgeons and Ledwich Sch. Med.

DEGREE OF M.CH.

Barron, J., Queen's Coll., Belfast.
Cowden, W. J., M.D., „
Crawford, G. B., „ „
Curtin, M. H., „ „
Dwyer, T. W. „ Cork.
Foott, R. E., „ „
Hawkins, W. R., „ „
McAleer, J., Queen's Coll., Galway, and Catholic Univ. Sch. Med.
McCarthy, M., Queen's Coll. Cork.
McWha, W. B. R., „ Belfast.
Marks, G. F. H., „ Cork.
Meenan, J., Carmichael Coll. Med.
Moore, J., M.D., Queen's College, Cork.
Musgrave, J., Queen's Coll., Cork.
O'Byrne, James P., Catholic Univ. Sch. Med.
Petticrew, R., Queen's Coll. Belfast.
Pooler, E. L., „ „
Ryan, John, Queen's Coll., Galway, and Catholic Univ. Sch. Med.
Sexton, W., Queen's Coll., Galway.
Smyth, N., „ Belfast.
Thomson, R., „ „
Tresilian, F. J., „ Cork.
Walsh, James J., Royal College of Surgeons and Ledwich Sch. Med.
Whitty, M. J., Queen's Coll., Cork, and Catholic Univ. Sch. Med.

DEGREE OF MASTER OF OBSTETRICS.

Connery, M., Queen's Coll., Cork.
Corny, A., Queen's Coll., Belfast.
Hannigan, M. H., Catholic Univ. Sch. of Medicine.
Hennessy, D., Queen's Coll., Cork.
McCarthy, M., „ „
McSwiney, M., „ „
McWha, W. B. R., Queen's Coll., Belfast.
Petticrew, R., Queen's Coll., Belfast.
Ryan J., Queen's Coll., Galway, and Catholic Univ. Sch. of Medicine.
Sexton, W., Queen's Coll., Galway.
Tresilian, F. J., Queen's Coll., Cork.

This degree was also conferred upon the following gentlemen in lieu of the diploma in Obstetrics which they had heretofore obtained:—

Barter, William.
Blackall, Patrick.
Bullen John W.
Craig, James.
Cromie, Thomas.
Hosford, Benjamin.
Johnston, G. J. W.
Le Grand, William J.
Lewers, Hugh.
McKee, Samuel.
McMurray, John
McVicker, Matthew.
Mangan, Bartholomew.
Matthews, Robert Huey.
Prendergast, Joseph M.
Roulston, William.
Rutherford, William.
Sheedy, John.
Strahan John.
White, Patrick Bernard.

Honours, Exhibitions, and Prizes were awarded as follows:—

SECOND EXAMINATION IN MEDICINE.—First Class Honours: Ambrose E. J. Birmingham, Catholic University School of Medicine.—Second Class Honours: John William Wilson, Queen's College, Belfast. [illegible] Ambrose E. J. Birmingham, Catholic University School of Medicine.

DEGREE OF M.CH.—First Class Honours and Prize of £20: William J. Cowden, M.D., Queen's College, Belfast.

DEGREE OF M.A.O.—First Class Honours and Prize of £20: Frederic J. Tresilian, Queen's College, Cork.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 28th ult.:—

Beddoes, Thomas Pugh, M.R.C.S., St. Thomas's Hospital.
Carpenter, George Alfred, M.R.C.S., St. Thomas's Hospital.
Howe, Joseph Duncan, M.R.C.S., Guy's Hospital.
Jones, George Selkirk, Charing-cross Hospital.
Winckler, Wm. Joseph, M.R.C.S., University College.

The following gentleman passed his examination in Surgery and Midwifery, and received a certificate to practise:—

Oliver, Charles Pye, Charing-cross Hospital.

IT is stated that the late Mr. Richards of Wednesbury bequeathed £1000 to Walsall Hospital, and a similar sum to the West Bromwich District Hospital.

MEASLES AT CHESTER. — Measles is still very prevalent at Chester; twelve deaths were, we understand, registered last week from the disease.

THE Nottingham Corporation has, it is reported, decided, at a cost of £141,000, to purchase a number of small unhealthy tenements in the centre of the town, and to erect upon the spot a hospital, at a further expenditure of £26,000.

BROMPTON HOSPITAL FOR CONSUMPTION.—During 1884 the number of in-patients treated at this institution was 1901, against 1763 in the previous year. The number of out-patients was 13,461, against 13,314 in 1883; and the number of attendances was 72,464. The total receipts amounted to £23,852, and the expenses to £24,467.

INTERNATIONAL INVENTIONS EXHIBITION.—We have pleasure in announcing that Mr. Trendell, superintendent of the Literary Department of the Exhibition, has consulted the convenience of the representatives of the press by causing writing tables with a supply of stationery to be placed in the rooms set apart by the Executive Council.

BRITISH MEDICAL TEMPERANCE ASSOCIATION. — The annual general meeting of the above Association was held on Tuesday, the 26th ult., in the rooms of the Medical Society of London, Chandos-street. Dr. Richardson, F.R.S., presided. The annual report stated that there were now 309 members and 42 associates, the former being medical practitioners and the latter medical students, all personal abstainers. An Irish branch had been successfully established (the first annual meeting of which was held on Tuesday last), and a branch for Scotland was just being inaugurated. For the 100 guinea prize offered by the Council for the best essay on the "Physical and Moral Advantages of Total Abstinence from Intoxicating Liquors" thirty-nine essays had been received, and were now in the hands of the judges. It is intended to declare the result and present the prize at a meeting of the medical students in October next. After the usual business, Dr. Richardson made a communication on "Recoveries from Alcoholic Paralysis under Total Abstinence," and Dr. C. R. Drysdale read a paper entitled "A Medical Reply to Lord Bramwell," which was followed by a discussion.

London Hospital. — A general court of the governors of this institution was held on the 3rd inst., when it was reported that during the past three months 1967 in-patients had been attended, of whom 649 had been discharged cured, 1097 relieved, and 201 had died while under treatment. There were now 616 patients in the wards, the daily average being 620. The out-patients had numbered 7800, and 9745 minor casualties had been treated.

Training the Deaf.—The annual meeting of the subscribers to the Society for Training Teachers of the Deaf was held last week at the College, Elmhurst, Ealing, under the presidency of Major-General F. C. Cotton. The seventh annual report stated that much good had been effected in making the Society's work more widely known. The Society had occupied a room at the Technical Institution during the Health Exhibition, and the actual teaching of deaf pupils in class was exhibited day after day for over five months.

The Darwin Memorial.—The marble statue of Charles Darwin, executed by Mr. Boehm, R.A., will be unveiled in the great hall of the Natural History Museum, Cromwell-road, on Tuesday next, at 12 o'clock, when Professor Huxley, P.R.S., chairman of the Memorial Committee, will formally transfer it to the trustees of the British Museum in trust for the nation. The Prince of Wales has consented, at the request of the trustees, to act as their representative to receive the custody of the statue.

Society for Relief of Widows and Orphans of Medical Men.—The annual general meeting of this Society was held on May 20th, Sir James Paget, President, in the chair. Mr. Lee and Mr. Cooper Forster were elected Vice-Presidents; Mr. Hogg, Dr. Barker, Dr. Roberts, Dr. Broadbent, Dr. Stokes, Mr. Latham, Dr. Ogle, Dr. Duka, Mr. Bennett, and Mr. Smith Turner, Directors. From the report for 1884 it appeared that the number of members of the Society was only 366, 4 less than in 1883; 13 new members had been elected, 12 had died, and 5 had resigned. The number of widows on the books was 61, showing an increase of 4; 5 fresh cases had been assisted, and 1 widow had died. The number of orphans had been increased from 5 to 8. A sum of £2853 had been given in relief during the year, and the expenses had been £215. A sum of £220 had been invested in the Metropolitan Consolidated Stock. The usual Christmas present had been made last year to the widows and orphans receiving grants. A discussion ensued on the best means of extending the operations of the Society by increasing the number of members; of over 4000 medical men residing within the limits of the Society, only 366 at the present time availed themselves of the opportunity to make a provision for their widows and orphans. The numerous appeals in the medical journals on behalf of the widows and children of medical men who had died young and left them totally unprovided for should lead many to join the Society, by which means they could at least secure a small annual sum for those whom they would otherwise leave destitute. A vote of thanks to the editors of the medical journals for their kindness in assisting in every way in their power in making known the benefits conferred by the Society was carried unanimously, and the proceedings were closed by a vote of thanks to the chairman.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning at the latest.*

Atkinson, William, M.D.Q.U.I., M.R.C.S., has been appointed Medical Officer for the Clapham District of the Wandsworth and Clapham Union, vice M'Donogh, resigned.

Bamber, Harry, M.B., C.M.Glas., has been appointed Assistant Medical Superintendent to the Fulham Union Infirmary, vice F. G. Ingoldby, M.R.C.S., L.R.C.P., resigned.

Bennett, Storer, F.R.C.S.Eng., F.R.C.P.Lond., L.D.S.Eng., has been appointed Dental Surgeon to the Dental Hospital of London, vice S. J. Hutchinson, M.R.C.S., L.D.S., resigned.

Benthall, Alfred Elliott, F.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Southern District of the Sherborne Union, vice Turner, resigned.

Brown, Martin Luther, M.B., C.M.Ed., has been appointed Medical Officer for the Brampford Speke District of the St. Thomas Union, vice Hunt.

Crabb, James, M.A., M.D., C.M., has been appointed District Medical Officer for St. Mary, Islington.

Cuming, Charles Henry, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Southern District of the Plymouth Incorporation, vice Prynne, resigned.

Jackson, Arthur, M.B., B.A.Oxon., M.R.C.S., has been appointed Assistant Medical Officer to the Surrey County Lunatic Asylum.

Jeram, Jas. William, L.R.C.P., L.R.C.S.Ed., L.S.A.Lond., has been appointed Medical Officer for the Hambledon District of the Droxford Union, vice M'Dougall, resigned.

Lewers, A. H. N., M.B.Lond., M.R.C.P.Lond., has been appointed Assistant Obstetric Physician to the London Hospital.

Mill, William, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Halford District of the Shipston-on-Stour Union, vice Palmer, resigned.

Osborne, C. Anthony Perrier, L.R.C.P.Ed., has been appointed Medical Officer of Health for the Huntingdon Urban Sanitary District, vice Oldman, deceased.

Phillips, Sidney, M.D.Lond., M.R.C.P., has been appointed Physician to Out-patients to the Children's Hospital, Paddington-green.

Smith, Chas. Jas. Hardy, M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Hawkhouse District of the Cranbrook Union, vice Hayes, resigned.

Walker, Hunter Urquhart, L.R.C.S.Ed., L.R.C.P.Ed., has been appointed Medical Officer of Health for Worksop, Nottinghamshire.

Weld, Chas. Humphrey, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Bodiham District of the Ticehurst Union, vice Hayes, resigned.

Wheeler, Daniel, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse, Chelmsford Union, vice D. M. B. Wheeler, deceased.

Wood, T. Outterson, F.R.C.P.Ed., F.R.C.S.Ed., M.R.C.S., has been appointed Resident Medical Superintendent of Sussex House and Brandenburgh House Asylums, vice Dr. L. S. Forbes Winslow, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Barnes.—On the 30th ult., at Boreham, near Hastings, the wife of Arthur Richard Barnes, M.B., of a daughter.

Bowman.—On the 26th ult., at Cricklewood, N.W., the wife of Richard Bowman, L.R.C.P., of a daughter.

Drew.—On the 20th ult., at Saville House, Buntingford, Hertfordshire, the wife of J. J. Bowerman Drew, L.R.C.P.S. & L.M., of a daughter.

Graham.—On the 30th ult., at Storrington, Sussex, the wife of G. H. Graham, L.R.C.P.Lond., M.R.C.S., of a daughter.

Johnson.—On the 1st inst., at Fern Lea, Upper Norwood, S.E., the wife of G. Lindsay Johnson, M.A., F.R.C.S., of a son.

Kibbler.—On the 23rd ult., at Mordaunt House, Hackney, the wife of W. Ambrose Kibbler, M.B., of a son.

Rigden.—On the 29th ult., at Burgate, Canterbury, the wife of Brian Rigden, M.R.C.S., of a daughter.

MARRIAGES.

Dickson—Carson.—On the 2nd inst., at St. Oswald's, Kilmalcolm, Renfrewshire, John Dunbar Dickson, M.D., of Marlow, Bucks, son of Henry H. Dickson, of Lansdowne-road, Dublin, to Emily Margaret, elder daughter of the late David Carson, of Glasgow.

Longman—Andrews.—On the 27th ult., at St. Michael and All Angels', North Kensington, George Philip Longman, M.R.C.S., L.R.C.P., of Donhead St. Andrew, Wilts, to Anna Louisa, widow of E. Andrews, and youngest daughter of the Rev. F. Elwes, Vicar of Gestingthorpe, Halstead, Essex.

DEATHS.

Arnott.—On the 27th ult., at his residence, Sussex-gardens, Hyde-park, James Moncrieff Arnott, F.R.S., of Chapel, Fifeshire, aged 91.

Blakeney.—On the 27th ult., at Dorking, at the residence of his youngest son, Edward Hugh Blakeney, M.D., F.R.C.S., Deputy Inspector-General, Army Medical Department, aged 76.

Bunny.—On the 2nd inst., at Newbury, Joseph Bunny, M.D., aged 86.

Cochrane.—On the 31st ult., suddenly, at Wickham Market, Suffolk, George Cochrane, M.R.C.S., L.S.A.Lond., &c., in his 77th year.

Dickson.—On the 26th ult., at South View, St. Heliers, Jersey, John Edward Dickson, M.B., C.M., in his 38th year.

Duke.—On the 30th ult., at Sevenoaks, Kent, Allen Duke, M.D., formerly of Chichester, Sussex, aged 75.

Fluker.—On the 25th ult., at Berwick-on-Tweed, Robert Carr Fluker, M.D., in his 69th year.

Holdsworth.—On the 1st inst., at Thames Ditton, Surrey, Dr. William Holdsworth, son of M. Holdsworth, Esq., of Grimsby.

Liddle.—On the 30th ult., at his residence, Bow-road, London, John Liddle, M.R.C.S., L.S.A.Lond., late Medical Officer of Health to the Board of Works for Whitechapel, aged 79.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, June 8.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10.30 a.m., and each day at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1.30 p.m., and each day at the same hour.

St. Mark's Hospital.—Operations, 2 p.m., and on Tuesdays at the same hour.

Hospital for Women, Soho-square.—Operations, 2 p.m., and on Thursday at the same hour.

Metropolitan Free Hospital.—Operations, 2 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Royal College of Surgeons of England.—4 p.m. Prof. John Wood: Hernia and its Radical Cure.

Tuesday, June 9.

Guy's Hospital.—Operations, 1.30 p.m., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 p.m.

St. Thomas's Hospital.—Ophthalmic Operations, 4 p.m.; Friday, 2 p.m.

Cancer Hospital, Brompton.—Operations, 2.30 p.m.; Saturday, 2.30 p.m.

Westminster Hospital.—Operations, 3 p.m.

West London Hospital.—Operations, 2.30 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Anthropological Institute of Great Britain and Ireland.—8 p.m. Prof. A. H. Keane, B.A.: On the Lapps (A family of Lapps will be exhibited, by the kind permission of the authorities of the Alexandra Palace).—Dr. J. G. Garson: The Physical Characteristics of the Lapps.—Dr. H. Rink: The Language of the Eskimo.

Royal Medical and Chirurgical Society.—Mr. J. Bland Sutton: Fatty Tumours.—Mr. Jonathan Hutchinson: Large Lympho-Sarcomatous Tumour of the Tongue; Excision; return two years afterwards.

Wednesday, June 10.

National Orthopædic Hospital.—Operations, 10 a.m.

Middlesex Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital.—Operations, 1.30 p.m., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 p.m.

St. Mary's Hospital.—Operations, 1.30 p.m. Skin Department: 9.30 a.m., on Tuesdays and Fridays.

St. Thomas's Hospital.—Operations, 1.30 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m., and on Thursday and Saturday at the same hour.

Great Northern Central Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2.30 p.m.

University College Hospital.—Operations, 2 p.m.; Saturday, 2 p.m. Skin Department: 1.45 p.m.; Saturday, 9.15 a.m.

Royal Free Hospital.—Operations, 2 p.m.

King's College Hospital.—Operations, 3 to 4 p.m.

Royal College of Surgeons of England.—4 p.m. Prof. John Wood: Hernia and its Radical Cure.

British [illegible] p.m. Specimens will be shown. Dr. [illegible] Shortening of the Round Ligamen[illegible] Inversion of the Uterus.

Thursday, June 11.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

The Church Missionary Society and Vivisection.

At a meeting of the Committee of the Church Missionary Society a letter was read from Miss A. Marston, dated 95, Onslow-square, on the subject of vivisection in its possible bearings on medical missions, strongly deprecating the practice, and appealing to the Committee to prohibit any experimentation on living animals in all schools and by all persons under their auspices and superintendence. It was resolved: "That the question of vivisection not having come practically before the Committee, they do not feel themselves called upon to give any opinion on the subject of Miss Marston's letter; but they have the *most perfect confidence in all their medical missionaries*, and feel sure that they will never permit, either directly or indirectly, any proceeding of an inhumane character to be carried on." The secretaries were directed to send a copy of this resolution to every medical missionary connected with the Society.

Gynecologist.—We believe the last American edition of Professor Lusk's work on Obstetrics and Diseases of Women and Children has been translated into French by Dr. Doléris, with a preface by Professor Pajot.

Dr. Thursfield (Shrewsbury).—*Next week, if possible.*

FATAL INJURY WITHOUT EXTERNAL MARKS.

To the Editor of The Lancet.

Sir,—The following case is perhaps sufficiently interesting to merit a place in the columns of your journal.

On March 10th last I was requested by the authorities to examine the body of a boy aged fifteen. The body presented no ecchymosis or external sign of injury. Upon opening the abdomen, a quantity of slightly sero-purulent liquid escaped. The peritoneum was everywhere highly inflamed, and thin patches of purulent lymph could easily be scraped off the bowel. On the front of the small intestine (jejunum), situated under the lower border of the last portion of the transverse part of the colon, was seen a bruise, the direction of which was longitudinal as to the bowel and transverse as to the body. This bruise was about an inch and a half in length and half an inch in breadth. Upon examining this bruised surface more particularly, a small opening was found communicating with the interior of the bowel, and, in fact, upon laying hold of the intestine a small amount of liquid fæces escaped. The other organs were all healthy.

The following is the previous history. A gentleman on horseback was passing along a road on March 8th, at 8 A.M., when this boy jumped off a wall into the road. The horse, being startled, kicked, striking the boy under the left false ribs. He immediately complained of great pain, which continued all day. No medical man saw him, but a prescription for a liniment was given, which was applied with little or no relief. He died at 11 P.M. on the Sunday night. The boy had always enjoyed excellent health. The interesting point in the case is the absence of any external mark of violence. This was specially searched for, as the history of the case was known to me before making the post-mortem examination. I am, Sir, yours obediently,

Arequipa, Peru, April, 1885. J. Dickson Hunter, M.D.Edin.

THE TIBBITS FUND.

To the Editor of The Lancet.

Sir,—Kindly allow me to acknowledge with many thanks the receipt of the following donations to the above fund.

Dr. Rayner	£5	5	0	Dr. Saul	£2	2	0
W. E. Rawstorne, Esq. ...	5	0	0	Dr. Wm. Collier	1	1	0
J. Palmer Gannon, Esq. ...	3	3	0	From "K."	1	1	0

Further donations will be thankfully received and acknowledged by Mr. Wm. Maw, Secretary to the Bradford Infirmary.

I am, Sir, yours truly,

Bradford, June 2nd, 1885. John Appleyard, F.R.C.S. & M.B.Lond.

Mr. R. de Cordova.

This gentleman, whose recitation of Gilbert's "Broken Hearts" met with well-merited appreciation before a crowded audience at Steinway Hall last week, is, we hear, a medical student who has thrown over medicine and taken to the theatrical profession. Mr. de Cordova, who is quite young, has a good flexible voice and finely cut mobile features, and he kept up the attention of his audience in a way which was most creditable in the absence of any of the ordinary stage accessories—costume, scenery, music. Mr. de Cordova has the accent of an educated gentleman, and has evidently much subtle appreciation of character.

Oil Immersion.—Frey's treatise on the Microscope is one of the best. Another, which is probably better adapted to our correspondent's requirements, is "Fol Lehrbuch der Vergleichenden Mikroskopischen Anatomie, Histologie, und Histogenie" (Leipzig, Engelmann, 1880); but the first part only is published.

THE MEDICAL COUNCIL AND GENERAL PRACTITIONERS.

To the Editor of The Lancet.

Sir,—A great deal of amusement seems to have been created at the expense of the general practitioner at the recent meetings of the General Medical Council. Surely, if for no other reason, the time is fast approaching, if it has not already arrived, when the general practitioner should be accommodated with a seat at the board of that facetious body; for if he were totally incapable of advising as to the education of the future medical student, he would at least be able to defend himself from the attacks which are now being made against him when he is not present, and therefore incapable of self-defence. If the stories of dead general practitioners are to be repeated, whether they are proven to be true or false, we may even hear of some more wonderful tales than those told at the last meeting of the General Medical Council. There is an old proverb that "people who live in glass houses should not throw stones," and it is just possible that general practitioners could tell as many amusing stories of those who frequently, from no abilities of their own, happen to occupy a position which is looked upon as being superior to that of their more lowly brethren. There is very little doubt that the general and scientific attainments and education of the general practitioner of the present day are far superior to those of even the physician of the past. I could, if I chose, relate many facts concerning the blunders of those who are at present engaged in consulting practice; but there is another proverb which hath it that "it is a foul bird, &c." If it be true that "Scotch graduates are not fitted to be good assistants," this may be one explanation why so many of them come over to this country and work for the miserable pittance which they so frequently do. From general practitioners I learnt how to diagnose small-pox, scarlet fever, measles, apply forceps, extract teeth, open an abscess, reduce a dislocation, set a fracture, pass a catheter, and a host of other things; also to show kindness and attention to the sick and dying when no physician could save them; and last, but not least, I have learnt to be kind and lenient to the weak, and to those who happen to be placed in a lower station of life than is the case of

Yours truly,

Albert S. Morton, M.R.C.S., &c.

Kennington-park, S.E., June 1st, 1885.

THE TITLE OF "DOCTOR."

To the Editor of The Lancet.

Sir,—In these days, when the bogey "red tape" is gradually vanishing before science and a clearer conception of justice, the question not unnaturally arises, so far as the medical man is concerned, What are the essentials of a Doctor of Medicine? The answer has always been: A man who has gone through a certain curriculum and passed certain examinations at a university, and attained a stated age. These, with a few exceptions, are the conditions considered necessary to become a M.D. But what for a man who has gone through a similar curriculum and passed similar examinations, perhaps even harder, but not at a university? Is he not equally learned in medicine? Then why should he be deprived of the right of using its Latin equivalent after his name? When the M.D. is supposed to be a criterion of ability of such importance, especially to a layman, surely it is a severe handicap and a moral injustice to deny this right. In the M.R.C.S.Eng. and L.R.C.P.Lond. we have a case in point. But, as you rightly observe in your leading article of the 23rd inst., many who have obtained these have passed a most insignificant preliminary in Arts. Why not, then, compromise? Let those whose preliminary has been a degree in Arts, the London University matriculation, the preliminary required for the F.R.C.S., or an equally difficult one, have the privilege granted at once; but let those whose preliminary has not been up to that standard complement it afterwards. They will then be Doctors of Medicine in fact—why not in name? If other claims to the title be needed, I think that the consideration of the better clinical teaching obtainable in London, which is one great inducement to the English student of medicine to come to the metropolis, the high fees required, and the making London to the English medical man what Edinburgh is to the Scotch, are very strong, and should at once counterbalance any prejudice that might arise from the absence of the name "university." Let all be equally dealt with, then none can complain.

I remain, Sir, yours obediently,

May 25th, 1885. Justus Sis, nec Timeas.

"DOCTORS v. PHYSICIANS."

To the Editor of THE LANCET.

SIR,—The letter of "Physician and Surgeon" in your last impression is of a somewhat aggressive character, or I should not have noticed it. In mine, under the signature of "M.D.," I had not intended to assume, nor do I think I did assume, any superiority of knowledge, leaving that to be judged of by my patients and others. I am quite ready to acknowledge that many surgeons and physicians, from experience and other causes, are the superiors in skill of some who hold the degree of M.D. in both branches of their profession, but in social status they certainly are not. A University degree is anywhere and everywhere acknowledged to give pre-eminence, and it was that feeling which induced me to take mine, residing, as I did, in a town where two others had recently done so, each prompted by a similar motive. We had all three passed our examinations long ago as surgeons and apothecaries, and were either consulting or acting officers in a provincial hospital, appointments which we all three held for many years with credit and respect. With regard to my own education, which is sneered at by "Physician and Surgeon," it consisted in the usual apprenticeship, one year of which was spent in a large county hospital, together with a clerkship and dressership at University Hospital, London. With regard to the education of the others I cannot speak, but I can as to the excellent use they made of it. Thus our degrees were certainly not taken because we had failed to reach the standard of your correspondent elsewhere. Mine was taken at the University of St. Andrews, one of the oldest in the three kingdoms, and almost the only one open to me, and my examination was a vivâ voce one, superior certainly to that of Apothecaries' Hall or the College of Surgeons, being conducted by four sets of Examiners and lasting altogether about an hour and twenty minutes, besides a series of papers to be written, occupying five hours on each of three successive days. There was also a separate vivâ voce examination in Materia Medica. So that the examination, if properly passed—and I had no reason to suppose it was not—was not quite such a farce as your correspondent would portray; and I conceived that the social standing it would give me would be higher than that I possessed before; and I should have the satisfaction of knowing that the title of "Doctor," by which I was so frequently addressed, and which is so frequently assumed without sufficient reason, would of right belong to me.

Now that I am writing on the subject, I will once and for all say what I think, and what I know many others think, of the movement which is going on to allow all medical practitioners to call themselves Doctors. The College of Surgeons bestows two titles—that of "Fellow" to those who have passed the qualifying examination, or to those who, like myself, have honourably earned it by length of service and experience, and that of "Member" to others. The College of Physicians bestows two similar titles—Fellow and Member—and, as far as I know, these are only granted to University graduates. The latter of these would justly be physicians, as in the other case of surgeons. But there is a third grade bestowed by the College of Physicians—viz., that of Licentiate, which has worried the College into granting to it what it was never entitled to, namely, the title of Physician also. Not content with this, it is now urging and persecuting the College into allowing it to assume the academical title of Doctor, which all those who have a just right to it are justly and properly opposed to. Why should it be allowed when, as I said before, it has cost those who possess it time, money, and inconvenience to obtain, all of which are to be trodden under foot and pass for nothing? "Physician and Surgeon" says there were other reasons why he did not obtain the title. Then why should it be conferred? In no other profession is a title conceded higher than that which is legally attained. As well might all barristers style themselves Queen's Counsel, or Masters of Arts style themselves Doctors. Let the College of Physicians maintain its own dignity, and do not let it give way to the clamour of those who would endeavour to assume its honours without earning them, and thus for ever depreciate them in the eyes of the world.

I am, Sir, yours faithfully,
M.D.

June 2nd, 1885.

Mr. E. Jones.—According to the statistics of M. Bertillon, the death-rates from both diphtheria and enteric fever in Paris have about doubled during the last decade.

C. J. S.—We would recommend that the matter be laid before the Local Government Board. The local authorities have behaved very shabbily, but we fear that legally they are within their rights.

VARICOCELE.

To the Editor of THE LANCET.

SIR,—It would be very interesting to know the opinion of experienced surgeons on the following points. Is varicocele usually the result of masturbation? Does it occur principally in connexion with sexual excess and involuntary emissions? Does it ever occur in a man who remains continent till twenty-five years of age? If a boy has varicocele, can any operation make him really fit for naval or medical service? I fancy that if anyone who has had varicocele be sent to India or West Africa he will break down just when most needed, though he may do for ordinary routine work. Are alcohol and sexual excess the main elements in causing varicose veins and general deficiency in elasticity of body and mind? What is the experience of army surgeons with regard to varicose veins in men reared in poverty in remote country districts, as compared with those reared in manufacturing districts and presumably more addicted to vice?—Yours truly,

QUESTIONER.

June 2nd, 1885.

COCAINE AS AN ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—I am loth to add to the numerous letters which have appeared in your valuable journal on the above subject; but, feeling that the very interesting communication by Mr. Copeland might prove misleading, I am emboldened to send you my experience of the action of cocaine upon the sensibility of the iris. In my opinion, the anæsthetic action of cocaine does not always penetrate as deeply as the iris, and I instance the following case in support thereof.

On Feb 28th, M. S——, a female aged forty-two, of calm demeanour and by no means nervous, was treated for the removal of a cataract from the right eye. A 4 per cent. solution of cocaine was applied to the eye at intervals of five minutes, and the operation commenced twenty minutes after the first application. The sclero-corneal incision was made without causing any pain; but directly the iris was seized by the iris forceps the patient started and complained of excessive pain. It was therefore deemed advisable to remove the cataract without performing iridectomy, and as the pupil was well dilated by the cocaine this was easily accomplished. By keeping the iris under the influence of atropine for a few days, and dressing the eye with cold-water compresses, the patient made an excellent recovery, and her sight was fully restored.

This case led me to decide not to use cocaine for iridectomy, unless under exceptional circumstances. The pupil generally dilates so well under the influence of cocaine that extraction without iridectomy is very easy, and, as far as I know, has not been followed by any untoward result.

Mr. Copeland's letter is incomplete in that neither the strength of the solution used nor the interval between the first application and the operation is given; it is therefore as much for the purpose of eliciting evidence on the effect of cocaine on the iris as to check the conclusion naturally drawn from Mr. Copeland's letter—viz., that when the conjunctiva is well under the influence of cocaine the deeper structures of the eye are also—that I have ventured to address to you the above remarks.

I am, Sir, your obedient servant,
WM THOS. JACKMAN, M.R.C.S.

Coggeshall, Essex, June 1st, 1885.

Bacillus.—Yes; Dr. Koch has been officially gazetted as Professor of Hygiene in the Medical Faculty of the University of Berlin.

A SUMMER ALPINE HEALTH RESORT.

To the Editor of THE LANCET.

SIR,—As there are many people by whom a salubrious and agreeable summer residence on the south side of the Alps is much desired, I am anxious to bring a very lovely and healthy locality under the notice of your readers—viz., the Hôtel Belvedere, Lanzo d'Intelvi, Como. The situation of the hotel is one of the most beautiful to be found anywhere. It stands at an elevation of fully 3000 feet above the level of the sea, with a magnificent view of Monte Rosa and its adjacent range, while at a depth of 2400 feet lies the Lake of Lugano, winding away in the distance. Behind the hotel stretches a fine old forest of chestnut trees, containing some of the grandest specimens of that tree to be found in Europe. In the forest, in addition to the chestnuts and interspersed among them, are to be seen many other kinds of trees, such as oak, elm, beech, birch, sycamore, hazel, lime, ash, tamarind, maple, walnut, and thorn. There are many delightful walks on the level, and donkeys are to be hired at the hotel. Monte Generoso, or Calvagione, is within easy reach for a day's excursion. Near Lanzo, and within a short distance of the hotel, are sulphur and iron springs. The climate is equable, with a soft yet bracing air, the temperature ranging from 61° to 73°. The subsoil is sandy and the atmosphere dry. The Hôtel Belvedere can be reached by carriage in three hours and a half from the following points:—Argegno on Lake Como, Osteno and Maroggia on Lake Lugano, the latter being a station on the St. Gothard Railway. The hotel, which is large and roomy, has been recently fitted up with every comfort, and has a billiard room and library, with a good lawn-tennis ground near the house. In the immediate neighbourhood are two dairies, by means of which the milk cure can be carried out. An English Church (S.P.G.) has been built, and there is a resident chaplain during the months of July and August, as also a resident physician. The hotel is a telegraph station. Being a comparatively new health resort, it is not yet mentioned in Baedeker, but this is to be rectified in the next edition.—I am, Sir, yours faithfully,

CHARLES SPURWAY, M.R.C.S.Eng., &c.

Rome, May, 1885.

Mr. A. J. Harvey's paper on the "Discovery of Self-Mesmerism" is declined.

THE DEGREE OF B.Sc. OF THE LONDON UNIVERSITY.

To the Editor of THE LANCET.

SIR,—Will you allow me to suggest, after reading the article in THE LANCET of this week on the Preliminary Scientific (M.B.) Examination, that, having regard to the amount of scientific knowledge men who have passed the Intermediate (M.B.) Examination possess, it would, to use the words of the article, be "both politic and fair" if the University of London awarded them the degree of B.Sc. Why should medical students have to pass four examinations before obtaining the honour of a degree when in all the other faculties only three are required, and when, after having passed their third examination, they are quite on a par with the inferior degree men in those other faculties? Simple justice demands that this honour should be extended to Intermediate (M.B.) men.

I remain, Sir, your obedient servant,
C. L.

May 22nd, 1885.

A CASE OF CATALEPSY.

To the Editor of THE LANCET.

SIR,—Judging by the text-books, cases of catalepsy are sufficiently rare to warrant my publishing this one.

Daniel L——, aged fifteen years, was admitted into the Mallow Union Hospital on March 27th, 1885. His pulse, temperature, and urine were normal; pupils equal; no paralysis; eyes staring. He would not answer any question or make any attempt to feed himself. He continued in the same state till April 1st, when, on taking up his wrist to feel the pulse, I noticed that it remained in the same position in which I left it. I then tested the arms and legs, and found them perfectly cataleptic. On April 2nd I again tested the limbs; they were still cataleptic. Next day he was not so rigid, and had some voluntary power. I was informed that he had spoken, but not coherently, to his grandmother on the previous evening. With Dr. Berry's assistance, I applied galvanism from the spine to the arm and the leg. After a short time he shrank away, and dropped the limbs which we had elevated. On April 4th his mother came to see him. She stated that on the night of March 22nd he awoke in a fright. He was not living with her, but was at service with a farmer at the time. She saw him on the 24th, when he spoke to her, but seemed "queer." There is no history of anything odd in the family. On this date (April 4th) I raised both arms and one leg at the same time and left the patient in that position for fifteen minutes. The arms remained up, but the leg dropped partially after some time. I again applied galvanism to the spine and the leg. He at once tried to roll away from me. From April 4th to the 8th he remained in the same condition, but on the latter day, on my raising his arms, he dropped them at once; he had, however, some voluntary power of movement. On the 11th he ate bread out of his own hand for the first time. On the following day he got up without help to the night-chair, ate all his own bread, and stole and consumed that of the patient next to him. He talked to the ward attendant, but would not answer when I spoke to him. From this date to April 17th he remained in an idiotic state, when he was sent to the idiot ward. His intellect, however, subsequently improved, and on May 21st he answered questions rationally, and will, I think, soon be able to return home.—I am, Sir, yours obediently,

FRANCIS W. GREENE, M.B. Univ. Dub.,
May 25th, 1885. Medical Officer, Mallow Union Hospital, co. Cork.

Mr. Holderness.—Such a consultation, though theoretically simple, is practically unsatisfactory, and to be avoided. Our correspondent would be justified in declining it; but we see no objection to his undertaking the charge of the case if the patient wishes it.

MINCING MACHINES.

To the Editor of THE LANCET.

SIR,—A few days ago I bought a mincing machine for use in the kitchen, and on looking into its construction I found that the working parts were made of lead. The machine consists essentially of a hollow cylinder of enamelled iron, in which there revolves a horizontal axle provided with a series of teeth which force the meat against the edges of a row of knife-blades set in a casting of lead. The axle and its teeth are all of lead. Is there any danger of lead-poisoning from the use of such a machine? The makers state in their advertisement that 80,000 of them have been sold; therefore the danger, if there is any, is a matter of some public importance. I am, Sir, yours truly,

Hatfield, May 18th, 1885. R. HUGHES.

The Cavendish Lecture

ON

HYSTERIA AND ITS COUNTERFEIT PRESENTMENTS.

Delivered before the West-London Medico-Chirurgical Society on Friday, June 5th, 1885,

BY J. S. BRISTOWE, M.D., LL.D., F.R.S.

MR. PRESIDENT AND GENTLEMEN,—It has often happened to me, when I have determined to speak or write on some special subject with which I had thought I was familiar, that, as I have pondered upon it with the object of bringing my facts and fancies into due mutual relation so that I might place them in the form of a compact and intelligible picture before my auditors or my readers, I have found my task grow more and more difficult with thinking upon it; I have found matters which I had perhaps hastily clothed with importance dwindle into insignificance; I have found what had seemed incidental and subsidiary questions assuming fundamental importance and pressing for solution; and I have discovered that, if I wanted to deal with my subject intelligently and adequately, I should have to bestow much more contemplation upon it than I had originally intended, and to treat it on different principles from those which suggested themselves to my mind in the first instance.

So it proved on the present occasion. It would be an easy matter, I thought, when I decided on the title of my lecture, to collect out of my experience a series of cases of hysteria and a parallel series which were not hysterical, to compare them, and to consider the lessons which such a comparison might teach. But as I proceeded with my self-imposed task, and began to bring into mental juxtaposition cases which I had regarded as hysterical and cases which I had regarded as not hysterical, I was compelled to ask myself more definitely than I had ever done before what were my grounds for applying the epithet "hysterical" to certain cases and for withholding it from certain other cases. I pondered over the matter; I puzzled myself; I came to conclusions that did not satisfy me; and at length, having wasted much time over it, I decided, after all, to treat my subject from the superficial point of view from which I had at first regarded it, and to reserve what little I had to say upon its more abstruse aspects for the close of my lecture.

I shall not attempt, then, at the present moment to define hysteria, or to consider in what respects hysterical disorders of the nervous system differ from other functional nervous derangements, or how they may be distinguished clinically from these and other groups of symptoms due to structural disease of the nervous centres, or of the nerves. But I shall assume, as is generally admitted, that hysteria represents an unstable condition of the nervous functions, arising independently of organic changes in the nervous system; in which at one time or another one or other part, or several parts, of the nervous organism may be temporarily affected in *various* ways; but in regard to which, partly from the conditions under which the symptoms of the disease arise, partly from the emotional state which is generally present, and partly from peculiarities in the symptoms themselves, in their mutual relations and in their course, there is, as a general rule, little difficulty in diagnosis. And I proceed to describe a selection of cases which, on the grounds above-stated, I have reasons to regard as hysterical, and to compare them generally, or in some of their most striking symptoms, with cases which, so far as I know, would not generally be placed in that category.

1. Mary D——, an emotional girl, nineteen years of age, was under my care for two or three months in the latter part of 1882. She was suffering from hysterical aphonia; besides which she presented a slight external squint of the left eye, and a narrowing of the left palpebral fissure and of the left side of the mouth, associated with a little twitching in the facial muscles of the same side. The aphonia was of recent origin, but no history could be obtained with regard to the affection of the face and eye. No material improvement took place. She came under my care a second time towards the end of 1883. She was still aphonic, and still presented her old facial peculiarities, but she was suffering from vomiting and emaciation, and from hysterical fits attended with much violence of convulsions. She was subjected to the Weir-Mitchell method of treatment, and at the end of three months left the hospital much improved, excepting in the symptoms for which she was originally admitted. On November 21st, 1884, she became my patient for the third time. She had remained aphonic, but suddenly, some three weeks before admission, had lost the power of articulation as well. She was still a very emotional young lady, with slight external squint of the left eye, a little narrowing of the left palpebral fissure (which Mr. Nettleship considered to be due to partial ptosis), some narrowing of the left side of the mouth associated with constant twitching of the angle, and a fidgety manner. She could not phonate, excepting a little when she laughed or coughed, neither could she articulate; indeed, when asked to speak, she merely moved her lips vaguely, as though not comprehending how to adapt them to the utterance of articulate language, but there was no paralysis of the larynx or of the mouth or tongue. Dr. Semon found that the vocal cords moved with the utmost freedom, that they often came into close juxtaposition, and that sometimes when apparently efforts were being made to phonate the rima glottidis became obliterated. The lips and tongue and soft palate, for all purposes but speech, were completely under her control. But though she could not speak, she understood what was said, and she could answer readily in writing. In addition to the above symptoms, it was discovered that she had anæsthesia throughout the left side (head, neck, arm, trunk, and leg), that she could neither taste nor feel with the left side of the tongue, that she could not smell with the left nostril, and that the perception of colours with the left eye was imperfect. There was complete absence of sensation and of reflex excitability in the soft palate and pharynx. The left ovarian region was tender. No very marked change occurred for some time. There was a little variation in the degree and distribution of the hemianæsthesia; and on one occasion, under the influence of a powerful magnet, there was temporary partial transference. I showed her and taught her how by smacking her lips, by similar action of her tongue, and by breathing through her upper row of teeth when resting on her lower lip, she could utter the essential consonantal sounds of *p*, *t*, and *f* respectively, but she made no further advance towards speech. She suffered much and constantly from headache, and occasionally from sickness; and early in January had a severe hysterical fit, in which she was violently convulsed and very rigid, but remained sensible. It ended in a fit of crying. After this she complained very much of headache and sickness, seemed ill, and ultimately took to her bed. She appeared still to be suffering thus when suddenly, late in the evening of March 10th, she called out "Sister," and at once the floodgates of her speech were opened, and she talked so volubly and incessantly that she had to be removed to a small ward for the night. From this time she improved rapidly, in nearly all respects. Her headache and vomiting gradually ceased. She became bright and cheerful, and useful in the ward, and looked and conducted herself like a sensible girl. But the paralytic phenomena on the left side of the face remained unchanged; and she was still anæsthetic, void of taste and smell, and partially colour-blind when, early in April, she was sent to a convalescent hospital.

Unfortunately, the history of the case does not end here; for, three or four weeks afterwards, she was brought back to the hospital with recurrence of aphonia and aphemia and, additionally, with somewhat severe general chorea. It will be recollected that on former occasions her manner had been fidgety, but her movements were not then characteristic, they were rather sudden and impulsive. But now they were typically choreic, and involved not merely the limbs, but the trunk, the head and neck, the face, the eyes, and the tongue. It was stated that the return of symptoms was due to her having been suddenly roused from sleep by one of her fellow-convalescents. She had never, so far as I know, had chorea previously; she had never had rheumatism; and no evidence of cardiac disease was ever detected. Within the last few weeks she has again suddenly regained speech and voice; but she is still under treatment for the chorea, which is improving, and for the anæsthesia and paralysis.

Now, that the above is essentially a case of hysteria will be generally allowed. The emotional character of the girl; the aphonia corresponding accurately with the aphonia, so often observed in hysteria; the hemianæsthesia, with involvement of the senses of smell, taste, and sight on the same side; the ovarian tenderness; the characteristic fits; and the rapid and unexpected variations in the symptoms—all furnish evidence of the correctness of that view. But was the aphemia also hysterical? Is the chorea hysterical? Are the persistent paralytic or spasmodic phenomena on the left side of the face hysterical?

That the aphemia was functional, and presumably therefore hysterical, cannot, I think, be doubted. The history of the case shows it. But aphemia is rare as an item of hysteria. At any rate, I have only once before met with it in a definite form; while aphonia is common. And yet when one considers the nature of the nervous disturbances by which aphonia and aphemia are respectively caused, and the close functional relationship there is between these two factors of speech, it seems odd that aphemia should not be a more common outcome of hysteria, and more often associated with hysterical aphonia than it is. It has been shown in this case, as I believe it has been shown in many other such cases, that there was no paralysis of the vocal cords, which could be brought into the most complete apposition, and into the position therefore in which phonation could not have been helped had the patient managed to breathe forcibly at the suitable moment. The defect was a hinderance to the proper transmission of the mental impulses to phonate to the ministerial centre by means of which the complex group of actions which subserve phonation are automatically coördinated, or a failure of this centre to act, or an impediment to the passage of the duly coördinated impulses along its efferent nerves. It has been shown also that there was no real paralysis of the organs of articulation. She understood speech, she could write, she could read, she was at no loss for words; but her organs of articulation, though free to move, did not respond to her mental impulses to speak. In fact in this case, as in the last, the defect depended not on any default of the supreme centre, but on some incompetence in a subordinate coördinating centre, or on some impediment to the transmission of impulses either between the supreme centre of speech and this coördinating centre, or between the last and the muscles it should control. That the nervous defect was in both cases independent of any structural change in the parts concerned, and involved simply what may be termed a hitch in the mechanism by which articulation and phonation are effected, is proved by the sudden temporary cures of the aphonia under the influence of galvanism, and the suddenness of onset and the suddenness of disappearance of both affections. The only other case of hysterical aphemia which I can recall is as follows:—A gentleman, about fifty-five years of age, with whom I was well acquainted, had been liable for many years to occasional fits, determined by mental excitement, which every doctor who had seen him in them regarded as hysterical, and which, from the description given to me, I thought were undoubtedly hysterical. On the occasion to which I refer there had been a serious panic on the Stock Exchange, and for some time it had been doubtful whether, through defaulting debtors, he would not lose a very large portion of his fortune. The excitement induced one of his so-called "hysterical" attacks, and this was followed for the first and only time by a total loss of the power of uttering articulate language, which lasted for several hours, and was then suddenly recovered from. He had no paralysis at the time, was quite sensible, could understand well all that was said to him, and could express himself accurately in writing.

But the same affection of speech may result from organic disease, implicating the centre or tracts of nerve tissue, presumably disturbed functionally in the cases just quoted. In 1870 I brought before the Clinical Society a very interesting case of the kind. The steward of a steam-packet was attacked suddenly while passing through the Straits of Banca, with a series of severe epileptic fits; on his emergence from which his limbs were powerless, he was stone deaf, and he could not speak. He was taken shortly afterwards to the hospital at Singapore, and was then still deaf and unable to speak, and paralysed on the left side. There was also slight right hemiplegia. He remained in hospital for some months, improved in many respects, and then came to England. He was received into St. Thomas's immediately on his arrival in this country, and just nine months after the onset of his illness. At this time he had manifest weakness in the left leg, complained of pain at the back of the head, and was unable to utter any articulate sound. But he had no paralysis of the organs of speech, he could understand perfectly, and he could keep up a conversation in writing. He had recovered his hearing and was also fairly well in all other respects. It was obvious that his inability to speak depended neither upon paralysis of the organs of speech nor on affection of the supreme centre of speech; but was due to some interference with the transmission of the impulses to speak from the supreme centre either towards or through the centre which regulates the mechanical details of speech. He had been speechless for nine months, and was no nearer speaking now than he was at the beginning of his illness. But he was a sensible man and (as I before mentioned) had complete control over the organs of speech for all other purposes than those of speech; and I determined therefore to endeavour to teach him to speak. I pointed out to my class and to him that the utterance of articulate sounds is a mere mechanical art; that for each letter-sound the organs of speech have to be arranged in a particular manner, and that if thus arranged, and their owner breathes or phonates, or suddenly opens or closes the oral passage, as the case may be, he cannot help uttering the articulate sound due to the particular arrangement of the parts at the time. And I illustrated my meaning by showing him, as I showed Mary D——, how, by certain simple manœuvres, certain simple consonantal sounds—such as those of *p*, *t*, and *f*—could be uttered; and how, by accompanying these several acts with phonation, *p*, *t*, and *f* become converted respectively into *b*, *d*, and *v*. I will not occupy your time by detailing how I, by repeated and progressive lessons, and he, by persistent and determined efforts, succeeded at the end of some weeks in restoring to him the use of articulate language. It is sufficient for me to say, that I first showed him how to utter the simplest articulate sounds; that, then, I taught him how to combine sounds; and that, after he had laboriously made some progress in these accomplishments, and especially after he had acquired some facility in combining two or three letters, his further progress was marvellous in its rapidity. I have quoted this as a case of aphemia dependent on organic cerebral disease; and judging from the patient's history and from the accompanying symptoms, I believe it was. But I admit that the complete recovery which took place is to some extent an argument in favour of the functional nature of his disorder.

Is the chorea which has latterly appeared in my patient to be regarded as hysterical? I do not think it has yet been proved that chorea is due to organic disease of the brain; and we know that (although it presents remarkable relations with heart disease, rheumatism, and scarlet fever) it is largely characterised by emotional disturbance often not unlike that met with in hysteria, and that hemianæsthesia and other symptoms not uncommon in hysteria occasionally become developed during its course. Considering how often rhythmical and convulsive movements of various kinds (some of which would certainly in former times have been called chorea) attend hysteria, it would seem not unlikely that symptoms identical with those of chorea should occasionally supervene as a part of the hysterical programme. A case bearing on this subject that was under my care three years ago has recently been published by my friend Dr. Hadden in *Brain*. In substance it is as follows:—A boy fifteen years of age was on December 20th attacked with a kind of fit, attended, it was said, with faintness, sickness, and convulsions. Similar fits recurred several times during the day, and from that time choreic symptoms showed themselves. On January 16th he was brought to the hospital, and in the casualty-room he was attacked with another fit, in which he became rigid, with convulsive movements of the arms and legs; but he was conscious, emotional, and cried when questions were put to him. His mother said that before the fit came on he complained of tightness at the throat and inability to swallow. When he came to, he was received into the general hospital, and was found to present characteristic general choreic symptoms with difficulty of speech. There was no cardiac disease. On Jan. 22nd he complained of a lump in the throat, jumped up, and would have fallen out of bed if he had not been caught. He rolled over on his face, sobbing. When turned over again his back became rigid and his limbs convulsed. He did not lose consciousness; he had no recurrence of fits; his chorea gradually subsided, and he was discharged well on Jan. 31st. The fits were in this case, I think, clearly hysterical; they seem to have ushered in the choreic symptoms, and they recurred from time to time during the progress of the disease. I cannot venture to assert that the chorea was in this case a phase of hysteria; but I think that this case, in association with that first narrated, and the fact of the emotional affinities between the two affections, render this view at any rate a probable one.

I now come to the paralytic state of the left internal rectus, and the peculiar condition of the muscles supplied by the left portio dura. The paralysis of the rectus was incomplete, but it was obvious, and she saw double. The left palpebral fissure was narrower than the right. The left oral angle was the more pointed, and that half of the mouth opened less widely than the other. Moreover, as I have pointed out, there was always a little twitching of this angle of the mouth, and of the muscles on the same side of the face. The condition of things was not unlike what results from an old attack of facial paralysis, in which recovery only short of perfection has taken place; the muscles regaining their voluntary power but becoming somewhat contracted and liable to flickering spasms. Mr. Nettleship was inclined to regard the narrowing of the palpebral fissure as due to slight ptosis. At any rate it is clear that the facial phenomena were due to affection in the domain of the third nerve and that of the portio dura.

We never got a very complete history of the case. But in the history we obtained there was nothing to show that she had ever had any acute affection of the portio dura, or that the squint and double vision were of old date. One argument against the functional origin of the phenomena is that since they were first observed they have presented no variation whatever; such as they were when she was first seen, so they remain. That hysterical patients may suffer from functional squinting I suppose there is no doubt. Within the last few days I have seen a young widow lady of twenty-five, who during the last month has for the first time in her life been suffering from the ordinary form of hysteria. But she informed me that during the previous ten years she had suffered from paralysis, at one time of one limb, at one time of another, and from loss of feeling, and that several years ago she suffered for some months from a squint and double vision for which she was treated by an oculist. She had no headache or sickness at the time. In relation to this question, I will also refer very briefly to two interesting cases admitted under my care within a few days of one another in the winter of 1882-83.

Eliza H——, a girl of nineteen, was attacked suddenly fourteen weeks before with right facial palsy, and six weeks later with weakness and numbness of the left arm and leg, the leg being affected later and less severely than the arm. She had no fit, headache, giddiness, or sickness. She had never had any serious illness before, nor had she been hysterical. On admission she was a plump and remarkably healthy-looking girl. The paralysis of the right side of the face involved mainly its lower part. She could wrinkle her forehead slightly, and could close her eye, but not firmly. The mouth was drawn over in the most remarkable way to the left side. It was almost wholly to the left of the mesial line, and the left angle was tucked up under her fat cheek so as to be scarcely visible. When she laughed the zygomatici on the right side acted slightly. There was very slight weakness remaining in the left leg. The arm, however, was decidedly weak. There was no anæsthesia. The optic discs were normal, and there was no evidence of disease in any other organ of the body.

Gertrude H——, a girl aged fifteen, after suffering for about a week with headache and giddiness, suddenly, a month before admission, began to squint, and three weeks later began to complain of weakness, numbness, and tingling in the right arm. She, like the other, was a plump healthy-looking girl. She had paralysis of both external recti, mainly of the left, with double vision, and impairment of sensation with marked loss of power in the right arm. She complained also of left-sided headache and some giddiness. The optic discs were healthy, and there was no sign of disease elsewhere. I may add that she, like her contemporary, presented a clean bill of health, and there was no evidence of her ever having displayed the usual symptoms of hysteria.

I need scarcely say that these two girls coming into hospital at the same time, and presenting a striking resemblance to one another in their histories and in their symptoms, attracted a good deal of clinical interest. And naturally, amongst others, the question arose whether their symptoms could be hysterical. I did not take this view of the cases; but you shall judge how far their future histories justify it. The former of these patients gradually but slowly improved. The paralysis of the arm and leg disappeared absolutely in the course of two or three months. The facial palsy made less rapid progress. It had improved by the end of three months, at which time the affected muscles presented the reactions of degeneration. She has called upon me from time to time since; and when I saw her a month or two ago, she was perfectly well, but for a trace of asymmetry in the lower part of the face. The latter patient has been under my care off and on down to the present time, and her symptoms have slowly progressed. She has suffered from variable headache, giddiness, and sickness ever since; the paralysis of the right arm and leg have become almost absolute, and hemianæsthesia of the same side has supervened; paralysis has spread to all her external ocular muscles, and complete ophthalmoplegia externa has resulted; and she has become liable to periodic epileptic seizures, always ushered in by two or three days of increasing high temperature. She has never had any trace of optic neuritis, and remains mentally in perfect health. I do not give the full details of this case partly because for my present purpose it is needless, and partly because I intend before long to publish it together with some other cases of the same kind. Now, were these cases hysterical? I am much more inclined than I was at first to think that this view furnishes the explanation of the former case, but I confess that I am by no means clear on the point. With respect to the latter case, I may state that I recently transferred it to another hospital, and the sister of the ward and the house-physician there settled between them to their own satisfaction that the case was hysterical, and that the girl was malingering. That she is not a malingerer I am absolutely certain. Whether the case can be regarded as hysterical depends on the limits one assigns to hysteria. I have reasons for believing that no organic changes will be found in the nervous centres after death. But the continuous progress of the case from worse to worse, and many of the special symptoms that are present, are not characteristic or even suggestive of hysteria. I do not think that these two cases are, in any sense, conclusive with respect to the question they have been adduced to illustrate; but I submit that my cases collectively point to the possibility of local paralysis being at times of functional origin, and, if of functional origin, occasionally, at any rate, hysterical.

To return to the subject of hysterical defects of speech. It is not only aphonia and aphemia which are met with in hysteria. The following case shows that we may have both stammering and aphasia. Two or three years since a lady, thirty-two years of age, consulted me. Many things, needless to recapitulate, had conspired during the previous eight or ten years of her life to make her emotional and to induce hysteria. About two years before I saw her she had an attack of "gastric fever." She was ill for a long time, and when convalescent became insensible for several days, and presented symptoms somewhat like those she consulted me for. Again three months ago she was ill for three weeks with symptoms of the same kind. Her present attack was of a month's duration, and was getting worse. Her condition was very peculiar. Women rarely stammer, and she was not an habitual stammerer. But now she stammered so badly that it was difficult to understand her. Her stammering moreover was odd. She began by repeating a word or two many times, then, perhaps similarly repeated one word and then the initial letter of the word, thus: "I think, I think, I think," then "I, I, I," then "think, think, think," and then the consonantal sound represented by *th*. Accompanying the stammering were rapidly repeated distortions of the face. These involved both sides, but were most severe on the right. The muscles of the eyelids twitched incessantly until the eyes were nearly closed. The corners of the mouth were similarly affected; and the other facial muscles, but in a less degree. The convulsive movements extended even to the muscles of the neck. She had difficulty in writing. Slowly and with deep consideration she could generally manage to translate printed words into written words. But when she tried to express her thoughts in writing she soon began to make hopeless blunders, and to repeat letters; nor could she succeed in writing her name. She could not recollect the forms of the letters she wished to use, nor could she recall their names. I tried to make her perform simple sums in addition, but she could not do it, and the figures were meaningless hieroglyphics to her. She said she could not read anything so as to understand it; that for the most part she knew the words which were actually under her eyes, but always when she reached any one word she had quite forgotten those that preceded it, and hence could not catch the meaning of even the shortest sentence. She could name anything she saw, but had great difficulty in recalling the names of things which were not present or visible. I saw her again about nine months later. I learnt then that all her symptoms had disappeared in the course of a few months, but that they had recently returned. She had had recurrence of stammering, but that was not present now. She presented, however, all the old spasmodic twitching of the facial muscles, all the old difficulty in writing and in the recognition of letters, and all the old forgetfulness of names of things not before her. She could not recollect the name of the day or of the month, and she told me that a few days previously she had had, as she thought, a serious and interesting conversation with a lady whom she knew, and who called upon her next day and asked her if she had not been ill, for she had talked nothing but nonsense. The patient had occasional attacks of unconsciousness, which, for anything I know to the contrary, may have been either attacks of syncope or epileptic seizures. I have no sufficient reason, however, for doubting that the case was essentially one of hysteria; and that was, I believe, the view of the medical man under whose charge she was.

(*To be concluded*).

REMARKS UPON THE

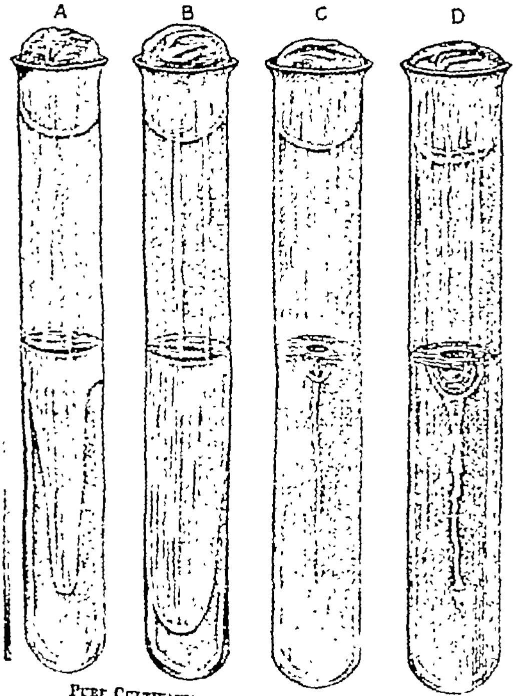
CHOLERA BACILLUS OF KOCH.

BY EDGAR M. CROOKSHANK, M.B.LOND.

THE works of Koch and his collaborators, of Hueppe, Johne, Babes, and others, have made us acquainted with the most recent and trustworthy methods of bacteriological research, which are of such especial importance in enabling us to decide the burning question of the present day—the etiology of Asiatic cholera. The interest in the discovery by Koch of a cholera bacillus, and in his methods of its investigation, is increased by the approach of summer and the possibility of a fresh outbreak in Europe. Consequently the attention of the profession and of the scientific world has been drawn to this subject throughout Germany, Italy, Spain, and France—in fact, almost everywhere; while this interest especially finds expression in America in the demands in the medical journals for a thorough acquaintance with scientific bacterioscopy, and in this country in the recent discussion at the Royal Medical and Chirurgical Society. The result of this discussion, however, though convincing to those who know how to appreciate the importance of the arguments brought forward by Watson Cheyne, Heron, and Warden, is in several respects very unsatisfactory, more especially for those who do not fully realise the minute and searching methods employed in bacteriological research by the school of Koch, and in the face of contradictory opinions the medical public remains without any guide. Having through the kindness of Professor Virchow shared the bacteriological laboratory of Dr. Babes in the Pathological Institute of Berlin, and for some time almost entirely restricted my attention to the study of comma bacilli, it is my aim in these remarks, by describing in the simplest form possible the methods employed, to enable all to judge for themselves, and, I trust, not only to appreciate, but to be convinced of, the searching arguments brought forward by Koch to prove the essential *rôle* of this micro-organism in the causation of the disease, and to be provided with a practical and sure means of diagnosing true Asiatic cholera. By reference also to some of the most recent researches, and by commenting upon some of the points raised at the above-mentioned debate, one can clear up many difficulties which lie in the way of accepting the conclusions of Koch. Those who are acquainted with Koch's comma bacillus can easily demonstrate its presence in the intestine in all cases of true cholera. Hitherto nearly one thousand cases have been examined by capable observers, and have given positive results; and there does not exist one observation which is contradictory, nor can one find the same microbe in other maladies. Physicians can therefore accept the presence of the comma bacillus of Koch as a pathognomonic sign of cholera, and in so doing it is an essential part of one's duty to become acquainted with its nature. The character of the comma bacillus is manifested in its habitat, its form, its cultivation, and its pathological action. The morphological characteristics have been fully described in the writings of Koch and in the reports of the Berlin Cholera Conferences, and need not be repeated; but inasmuch as it is often difficult to distinguish other bacilli which are present in the ejecta from the bowels and resemble it more or less in microscopical appearance, it is most essential to become familiar with the methods of pure culture which have been employed by Koch.

It is necessary, however, to obtain a characteristic culture, always to employ a 10 per cent. gelatine, slightly alkaline (Babes), and as it is difficult to prepare, it would be best to procure it ready made. Provided, then, with ready prepared sterilised tubes, a platinum needle (two or three inches of fine platinum wire fixed at the end of a glass rod), a few dinner- and soup-plates, half a dozen small panes of glass (6 in. by 4), a solution of sublimate (1 in 1000), a common dinner knife, some potatoes, methyl violet, a microscope, and its usual appendages, the medical man (especially the medical officer of health), who has not access to the elaborate apparatus of a bacteriological laboratory, has all that is required for conducting the simple methods which Koch often had recourse to and employed with success in India. For the plate cultures improvise a damp chamber by utilising a common dinner plate and a soup plate, both previously washed with sublimate, the plate having a piece of filter paper laid upon it, which is also moistened with sublimate. A small plate of glass, sterilised by carefully heating one surface over a spirit lamp, is placed on the filter paper, as level as possible, with the sterilised surface uppermost. Prepare two such chambers, then liquefy the gelatine-peptone broth in two tubes, and introduce into one by means of the platinum needle a mucous flake from choleraic discharge, and stir it well up; from this inoculate the second tube by introducing the needle five times, and stirring round as before. Lastly, pour the gelatine out on the plates in the form of a ring, so that every part can be brought into the field of the microscope. At a temperature of from 16° to 20° C. little specks commence to be visible in about twenty-four hours. They consist of isolated colonies, and when examined with a low power and a small diaphragm have the following characteristics. They appear as little masses, granular, and slightly yellow, *and of a* faintly yellowish-red tinge. They liquefy the gelatine, sink down, making a little excavation, at the bottom of which one recognises the little punctiform colony. By means of the platinum needle, with the extremity bent into a miniature hook, one can, under the low power of the microscope, select and pick out a typical colony and *inoculate* a tube. Another colony can be selected in the same way and well spread out with a needle on a cover glass, and stained after the method of Babes. This consists in putting on the cover glass so prepared a drop of a weak aqueous solution of methyl violet (B) and leaving it for a minute; then place the cover glass on a slide, and with *filter paper* remove the excess of liquid, and examine. A rapid examination is thus made of a pure culture of the bacilli. In about twenty-four hours the tube-culture commences to display its absolutely distinctive appearance. Liquefaction sets in slowly, commencing at the top of the needle tract around an en*closed bubble of air, and forming a funnel* continuous with the lower part of the needle tract, which preserves for several days its resemblance to a white thread (Fig. C, D). In about eight days, however, this too is liquefied, with the exception of the deepest part of the needle tract, which disappears only at the moment when all the rest of the gelatine underneath it is liquefied. Babes has shown that the cultivation on an oblique surface of agar-agar peptone-broth is also quite characteristic. By inoculating the surface vertically with the needle, in about two days a culture is developed in the form of a plate, semi-transparent, and with well-defined margin, while the liquid which exists at the bottom of the oblique surface becomes milky. If one compares this with *the behaviour* under similar circumstances of other comma bacilli, the difference is in all cases easily appreciated. The potatoes are prepared by removing eyes and rotten spots, well washing, soaking in sublimate for half an hour, and then steaming for the same length of time. Holding them, with the fingers previously dipped in sublimate, they are cut in two with a knife which has been sterilised by heating in the flame of a spirit lamp, then placed in damp chambers extemporised as before, and inoculated by smearing the micro-organisms over the surface with the flat of the knife. Koch's comma bacillus will only grow at the temperature of the blood (37° C.), forming a slight brown transparent layer.

If, on the other hand, we are dealing with a case of cholera nostras, we shall by the same procedure produce the characteristic biological appearances of the Finkler bacillus. In the tube culture we find that the gelatine in two or three days is liquefied along the whole tract of the needle puncture, excavating the gelatine in the form of a conical sac, and resembling in some degree the finger of a glove turned inside out (Figs. A and B). In glass plate cultures the colonies have a slightly yellowish-brown colour; but they are larger and rounder than the colonies of Koch's bacillus, have a well-defined border, and under a higher magnifying power a distinctly granular appearance. They liquefy the gelatine much more quickly, and give rise to a penetrating odour and rapidly become irregular in shape. Even in two or three days the gelatine on the second plate with only a few colonies is altogether liquefied. On agar the Finkler bacillus forms a white layer much more quickly; the liquid at the bottom of the oblique surface also becomes milky, but after a certain time a brown, coffee-coloured layer appears, which is very characteristic. On potatoes the Finkler bacillus grows rapidly at the ordinary temperature of the air, the culture has a brownish colour with a whitish border, and the surface of the potatoes appears to be eaten in.



PURE CULTIVATIONS IN GELATINE-PEPTONE-BROTH.
A. Finkler's bacillus, twenty-four hours old.
B. " " two days old.
C. Koch's cholera bacillus, twenty-four hours old.
D. " " " two days old.

Other comma bacilli differ in that they cannot be cultivated on gelatine, with the exception of a comma bacillus very frequently found in water. This liquefies gelatine very slowly, and forms on its surface a white pellicle (Babes). The last link in the chain of evidence is afforded by the effect of the inoculation of a pure culture of Koch's comma bacillus in animals. Nicati, Rietsch, Koch, Ermengen, and Babes have inoculated the bacilli with success in the duodenum. Babes, who used all practical antiseptic precautions, had three successful cases out of six; the guinea-pigs, which were the animals experimented upon, exhibited at the post-mortem examination the appearances produced by cholera without any trace whatever of peritonitis or putrid infection. In the intestine, in the mucus typical comma bacilli were found and pure cultivations obtained. Recently it is reported that Koch, by a new method, without forming any lesion, has produced choleraic symptoms, without exception, in a great number of animals. Koch and Babes have also studied the pathological appearances produced by the cholera bacillus. They have found in all cases, more or less, in the intestine that the epithelium to a great extent is missing, the superficial tissue necrosed, the glands dilated, their epithelium swollen, in the glands and sometimes in the inflamed tissue more deeply, and in the necrosed parts they have established the presence of the micro-organism. In internal organs of chronic cases affected with parenchymatous degeneration, round or oval bacteria are sometimes seen; they are also pathogenic (Babes), but these latter are not in any way characteristic of cholera, but are considered to be merely the result of septic complication.

From these investigations we are led to the following conclusions:—That the presence of the cholera bacillus of Koch is quite characteristic of cholera; that the comma bacilli of Koch exist in the tissue of the intestine; that they are, there is every reason to believe, the actual *causa causans* of cholera. With regard to the second statement, one can only conclude that if observers have failed and do fail to find the bacilli in the tissues, it must be that either they are not masters of the technique, or that they have not sufficiently sought for them. The method employed by Babes is to cut very thin sections of a recent case of cholera, if possible immediately after death, and especially from the immediate neighbourhood of a Peyer's patch. Then leave the sections for twenty-four hours in a watery solution of fuchsin (fabrique de Bale), wash a little in sublimate (1 in 1000), pass rapidly through alcohol and oil of cloves, thoroughly dry with filter paper, and preserve in Canada balsam. From material supplied by a case examined by Babes in Paris I have also succeeded, by closely following his method, in staining the bacilli in the tissue and demonstrating their presence with a Zeiss $\frac{1}{12}$ oil immersion lens. With regard to the inoculation of animals with cholera bacillus, one must confess that it is not easy to avoid peritonitis or accidental infection, but it is easy to be convinced that if one does avoid these errors one will have a certain number of cases which give positive results. That Dr. Klein has so often encountered accidental infection may account for his want of success. Emmerich has asserted that he has found in the internal organs a special microbe which causes choleraic symptoms by inoculation. This, however, is in direct contradiction to all other observers, who have shown, like Babes, that if there be a pathogenic microbe present in the organs, it has penetrated through the necrosed tissue of the intestine, and that it is nothing more nor less than a pyogenic or septicæmic bacterium.

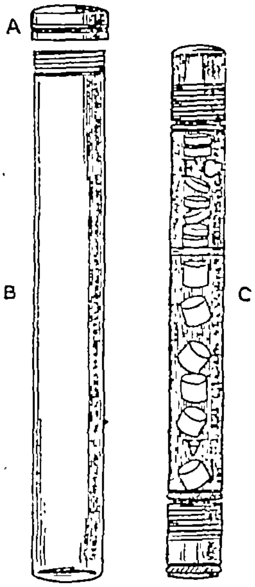
FERROCYANIC TEST PELLETS FOR ALBUMEN.

BY F. W. PAVY, M.D., F.R.S.

THESE pellets afford a ready, portable, reliable, and delicate clinical test for albumen. They require no spirit lamp to be employed and supply information which can be accepted without needing the application of any other test for correction or corroboration. When albumen is present it does not fail to be indicated by the production of a precipitate; and, on the other hand, when a precipitate is produced albumen, as far as I yet know, is the only principle that occurs in the urine to occasion it. With these qualities the ferrocyanic test commends itself as specially adapted for general use in medical practice.

The sketch on the following page shows the portable character of what is needed for the application of the test. The whole appliance can be carried in the pocket like a pencil case, which it only to a trifling extent exceeds in size. There is a celluloid tube (C) for holding the pellets, and this fits into a glass tube (B), which is employed as the test tube. No heat being required for the application of the test permits the glass tube to be made of sufficient thickness to be carried in the pocket without danger of breaking. The celluloid tube has a partition inside to keep the acid and ferrocyanide pellets separate, and at either end there is a screw top. The glass tube is provided with a metal cap (A), which screws on and closes it. Messrs. Maw, Son, and Thompson of Aldersgate-street make the apparatus.

Under the form of acetic acid and ferrocyanide of potassium, the ferrocyanic test has for a long time been favourably regarded as a delicate test for albumen. Senator, in his recently published monograph on albuminuria, in referring to the drawbacks belonging to heat and nitric acid, speaks thus[1] of the test:—"As, however, notwithstanding these drawbacks, the test in question [heat and nitric or acetic acid] is the only one in common use, it will not be superfluous to give a brief account of far more reliable tests which should be used in doubtful cases, or I would rather say, in all cases in future. These are as follows: (1) To acidify the urine with acetic acid and then add carefully a (concentrated) solution of ferrocyanide of potassium, according to Hofmeister the most delicate of all the tests for albumen, and which precipitates all the albuminous bodies, but not peptone." To adapt the ferrocyanic test conveniently for clinical use, it occurred to me to follow what I had already done as regards the cupric test for sugar, and bring it into the pellet form. At first I placed the acid (citric) and ferrocyanide in the same pellet, and these pellets were introduced to the notice of the profession at the Clinical Society in the early part of 1883. Subsequently, for reasons that presented themselves as experience was gained with the employment of the test, the agents were placed in separate pellets, and it is in this form that I now recommend it. As the pellets are devoid of any foreign principle whatever, there is nothing to undergo deterioration by keeping. Citric acid is just as eligible for the purpose required as acetic acid. Enough is supplied in the pellet to secure the presence of free acid in any alkaline specimen of urine that is likely to be come across, provided the quantity mentioned in the instructions for the application of the test is taken. Should any doubt exist, two pellets can be used in place of one. The ferrocyanide pellet consists of the sodium instead of the potassium salt, on account of its yielding a looser and more speedily soluble product. The pellets are made by Mr. Cooper of 66, Oxford-street.



In using the test about a drachm of urine is taken as the quantity to be employed. An acid pellet is dropped into it, and with a little agitation is found to be quickly dissolved. One of the ferrocyanide pellets is next dropped in, and the urine again shaken to facilitate solution. If albumen is present, a precipitate immediately appears.

It is necessary that the test should be used in the manner which has been mentioned—that is, the acid pellet must be first dropped in and dissolved, and then the ferrocyanide pellet added. The latter pellet it is which supplies the information required, and if a precipitate is by this pellet produced, the conclusion may be drawn that albumen is present, for the test does not precipitate peptones or other principles incidentally present in the urine. For sensitiveness the ferrocyanic will bear comparison with any other albumen test; and should no precipitate be rendered visible it may be safely inferred that no albumen is present. There is no need therefore for anything beyond the *test itself* being employed, and no spirit lamp being required, gives it a great advantage.

It occasionally happens that a precipitate is produced by the acid pellet alone, but no fallacy should arise from this. It is the ferrocyanide pellet which affords the evidence of the presence or absence of albumen. The acid pellet only supplies a preparatory condition to allow the ferrocyanide to act, and does not constitute the test. The usual source of the precipitate referred to is uric acid, and by diluting the urine with about an equal bulk of water, it is prevented from appearing. In this way the interference thus occasioned to the application of the test is removed. Mucin also is precipitated by an acid, and the best plan here is to take two test tubes and to treat the urine in one with the acid pellet alone, and in the other with both pellets. A comparison of the two will show whether albumen is present or not.

Should the urine be turbid from lithates, it may be cleared either by the application of moderate warmth, or, what may be more convenient, the addition of about an equal bulk of hot water.

A most portable little case is made by Jahncke of Canonbury Works, Dorset-street, Essex-road, N., which contains the two kinds of pellets for albumen, the cupric test pellets for sugar, a spirit lamp, test tube, and urinometer. This gives all that is required for the ordinary examination of the urine, and makes an elegant, compact, and convenient little case.

Grosvenor-street, W.

THE ETIOLOGY OF GOITRE IN ENGLAND[1]

BY W. N. THURSFIELD, M.D.

As a rule the subjects which are brought for discussion before the Society of Medical Officers of Health relate either to matters connected with sanitary administration, or to infectious disease, or to influences acknowledged *to directly* affect the health of the community. As goitre may not at first sight appear to belong to either of these classes, it may be as well for me to state that my attention was first directly drawn to this subject about three years ago, in consequence of my being requested by a sanitary authority to inquire into an epidemic prevalence of goitre amongst the children in some schools in their district. The undoubted epidemic nature of the disease and other facts were so diametrically opposed to the etiological views almost universally given in the text-books on medicine, that I was induced to make further investigations as to the general liabilities of the population and physical characteristics of certain districts where goitre was endemic, and, in order to *avoid hasty generalisation* from general conditions, which may have been merely coincidences, to check these observations by particular inquiries in individual cases, wherever opportunity offered.

I have restricted my conclusions as to the cause of goitre *to the disease as it occurs in England, because* I wish to confine myself as far as practicable to personal experience, and there may be in other countries contributing causes of which I have no knowledge. It would, for instance, be interesting to know why in India goitre should be nearly as *common in men as in women.*

For a definition of goitre I do not think I can do better than follow the official nomenclature of the Royal College of Physicians, which defines goitre as "enlargement of the thyroid gland, endemic in certain mountainous districts, but *not limited to them.*" This enlargement depends upon simple expansion, hypertrophy of tissue, or vesicular distension, or a combination of all three, and results from persistent abnormal increase in the blood in the gland, or persistent abnormal call upon the physical action of the gland, and usually upon both combined. Goitre is much more prevalent amongst females than males, and certainly in my experience affects in undue proportion the industrial class. The primary causes of goitre are as follows: (1) Climatic, (2) physiological (including sex, heredity, &c.), (3) industrial, (4) dietetic, (5) neurotic and strumous diathesis.

In localities where goitre is endemic two of the above causes are always present, and generally three or four, in various degrees of preponderance, and the preponderating cause will often be found to differ in different localities. Sporadic cases of goitre occurring in localities where goitre is not endemic, when not directly imported, are the result of the preponderating influence of some one or two of the above causes, probably conjoined in many instances with the influence of heredity. The causes are mentioned in the order it will be most convenient to *consider* them. I have not referred to absence of sun light, confined atmosphere, and other causes considered as contributing in some countries, as these are not in my experience concerned in producing English goitre.

---

[1] Sydenham Society's Translation, 1884, p. 11.

[1] Paper read before the Society of Medical Officers of Health, May 15th, 1885.

The Climatic Influence.—This is as a rule the chief factor in the production of endemic goitre. Endemic goitre may elsewhere exist in low-lying plains, due doubtless to the combination of some of the causes above alluded to; but in England, so far as my experience goes, the endemic prevalence of goitre is not found at much less altitude than is indicated by a fall in the column of mercury equal to about three-quarters of an inch. This diminished atmospheric pressure in hilly districts, together with the climbing of hills and other conditions leading to sudden alterations in the circulation, combined with the natural distensile property of the thyroid, is, I believe, the origin of the goitrous diathesis. In the goitrous districts abnormal enlargement of the thyroid occurs at any age up to adult life. At the present moment I could show cases at almost any age from infancy upwards. It appears, however, usually to show itself from five to twelve years of age, perhaps most commonly at about eight years of age; but where medical advice is sought, it is not generally until a marked enlargement coincides with the first catamenial period or some other cause interfering with the circulation. It is this circumstance, I think, which has given rise to the statement found in most text-books that it is at the above period that goitre usually makes its first appearance. It is my experience that a much larger proportion of cases of enlargement of the thyroid in a goitrous district will be found in females under the age of thirteen than above it. The enlargement in the majority of cases then disappears; in some, however, it is persistent and increases much, and it is these cases which are ordinarily known as goitre. This persistence is owing to causes specially interfering with the circulation of the thyroid or otherwise conducive to hypertrophy of the gland. The cause most directly conducive is, however, diminished pressure of the atmosphere.

The Physiological Influence.—Of the thyroid gland little is definitely known beyond its anatomical structure, which is that of a very vascular ductless gland, with a dual supply of bloodvessels and nerves from different sources. The thyroid has this peculiarity, that of all the glands of the body which we can see and feel it is most prone and most capable of alteration in volume, and it is to this peculiarity that goitre is due. It is, in fact, the giving way under varying degrees of increased force below, or diminished pressure above of the point of least resistance in the human body externally. In other words, the abnormal and persistent expansion of a structure normally distensile for physiological reasons. I have no personal information on the point, but it is stated that goitrous tumours increase in size in wet weather—i.e., with a low barometer; and a locality with a high local humidity might in the same way be a contributing influence. The function of the thyroid in the human body appears to be of a double nature—one almost mechanical, the other physiological. One purpose served by the thyroid appears to be to act as a diverticulum for the circulation on the occurrence of arterial tension in the brain or uterus. That it should so act in the case of the intercranial circulation might be anticipated from the very intimate anatomical relation between the arterial supply to both, and cases have been recorded of acute goitre supervening on intense excitement. This function or habit of the thyroid has much to do, as will be presently shown, in the production of goitre. That it does so act in the case of the uterus is also an observed fact, sudden enlargement of the thyroid frequently supervening in connexion with menstruation and pregnancy, and in some cases a periodical expansion occurs. As no direct anatomical connexion between the uterus and the thyroid is traceable, we are driven to the explanation of correlation of nerve influence between the two organs. That intimate sympathy exists between the generative organs and those of the throat is obvious from well-known facts; and the liability of sudden enlargement of the thyroid to follow uterine excitement appears to have been utilised for practical purposes both in classical and mediæval times. This function or habit of the thyroid would account for the greater liability of the female to suffer from enlarged thyroid. The thyroid is at all ages normally proportionately larger in the female than in the male; and the fact, as I have observed, that the preponderance of cases of enlarged thyroid amongst females is found, though perhaps not to the same extent, in childhood as in adult life, is evidence that this special liability is not, as has been suggested, owing to the greater use of water as a beverage by females, but is a liability of the sex, and doubtless the result of a natural provision for equalising the sudden alterations in the circulation to which females are specially liable.

As regards the function of the glandular apparatus of the thyroid (the vesicles, &c.), little is known definitely. Physiologists seem generally to agree that the gland performs some office in connexion with the composition of the blood. Dr. Baber frequently found the vesicles to contain red blood-corpuscles in various stages of degeneration and decolourisation, and concluded that the gland was concerned in the retro-transformation and excretion of the elements of the red blood-corpuscles. This assumption, if correct, has a most important bearing, and may help to throw light upon the mysterious but undoubted occasional connexion between the use of certain drinking waters and the production of goitre, and will be referred to subsequently in connexion with that point. Goitre has a most decidedly hereditary tendency. I have seen many such cases both direct and collateral. It has been suggested by Dr. Woakes, on analogical grounds, that this hereditary tendency would be most marked where there was a strumous taint, inducing goitre by abnormal relaxation of the arteries of the gland, the result of neurosis of the cervical ganglia. The cases, however, in which I have noticed heredity have generally been of a high physical standard of development, and of an average intellectual standard.

The Industrial Influence.—That goitre is frequently entitled to be considered an industrial disease I entertain no manner of doubt whatever. Carrying weights on the head or otherwise, so as to interfere with the cerebral circulation, is a most potent contributing cause. It requires, however, to be combined with the climatic or some of the other influences alluded to, and even in goitrous districts I have obtained strong evidence that for the industrial influence to be operative it is necessary as a rule that it should commence at or soon after puberty. I am well acquainted with two populous localities both situated at an altitude of about seven hundred feet. In both goitre used to be endemic, and is so to some extent at the present time. In both the water-supply is the same as it has been from time immemorial; in both there has been a most marked diminution in the number of cases of goitre, especially of the more severe kinds, and the only alteration in the habits or liabilities of the inhabitants which could at all affect this has been the cessation on the part of the young females of the locality of the habit of carrying weights on the head in their employment in connexion with the coal and ironstone mines, also their daily water-supply, &c.; as having acquired the ability to readily carry weights on their heads, they adopted that mode of carrying everything. The present generation of females in the locality, not having had a similar education, carry water &c. in the ordinary way. Of one of these localities I have intimate knowledge, and well remember as a boy passing through the streets to have frequently noticed the repulsive looking huge goitrous tumours of a kind one seldom, if ever, sees now. At the present time the alteration is most marked and is at once admitted by the older inhabitants. This district is a mining and manufacturing one, more flourishing years ago than now, and situated close to a navigable river, and no explanation of greater mixing of population and cessation of intermarriage would apply here. The only alteration here has been industrial. Years ago this locality was so notorious for goitre as to give a name to the affection in that part of England. The women were also celebrated for their ability to steadily carry great weights on their heads, and at certain seasons of the year many of them were engaged to go to other localities and occupations where such an accomplishment was desirable. Following up this clue, I have found several instances of sporadic goitre where the only member of the family affected with goitre has been the only one who had carried weights on the head habitually; these have generally been people dwelling at a considerable altitude. In carrying weights on the head the return circulation of the neck is retarded and the arterial stimulated, conditions directly tending to congestion of the thyroid, and this I believe to be the most potent industrial influence, but any heavy exertion has a tendency to the same effect; and this would probably explain the not unfrequent cases in which domestic servants develop goitre in non-goitrous districts. In these cases there would, I think, generally be present hereditary tendency to goitre or a strumous and neurotic diathesis. I have ascertained that the traditional practice of one eminent medical man who practised in a goitrous district in the midlands before the introduction of iodine was to strictly enjoin upon his goitrous patients the necessity of not carrying weights on their heads and to boil the drinking water. This boiling of the water was probably intended to get rid of some of the lime salts, but it would also precipitate the iron where lime was present.

The Dietetic Influence.—If in my investigation into the origin of goitre I could have made my mind a complete *tabula rasa* as to all that I had previously heard or read on the subject, I do not think I should have found it necessary to consider the probable influence of the water at all in the matter. I am, however, disposed to think that in some of the localities water was certainly a contributing cause. In each of these cases a theory of excess of saline and earthy matters in solution, or of iron in solution in small quantities, would have been equally applicable. I have adopted the theory of iron, as it appears to me that it can be more readily and scientifically connected with hyperæmia of the thyroid body than excess of dissolved matter in the water consumed. In looking through the various text-books of medicine, nothing is more striking than the uniformity with which the quality of drinking water is assigned as the cause of goitre, though on the question of the element in water producing the evil the diversity of opinion is almost as remarkable. Personally I venture to express a belief that water is by no means essential to the production of the disease, and has frequently nothing to do with it. That every kind of water from snow-water downwards has been credited with producing the disease is presumptive evidence that water in some instances has had nothing to do with it, and I am satisfied that under favourable conditions of climate and industry goitre may occur altogether independently of the water, and, in the epidemic above alluded to, the water-supply of the majority of cases was derived from the hard Cambrian formation, and to quote the report of the well-known analyst, Mr. Sutton of Norwich, was "one of the purest natural waters which had ever come under his notice or of which he had seen any record." It did, however, contain slight traces of iron. Indeed, the very fact of the existence of an epidemic is, in the case of such a disease as goitre, strong evidence that water had nothing to do with the malady. Water has, however, been credited as the cause of goitre from the earliest records of medicine, and there is abundant testimony that it is often a potent contributing cause of the affection. To my mind no satisfactory explanation as to how it acts has yet been afforded, and on this point I speak with special diffidence. The theory I have to offer in the explanation of the goitriferous property of certain waters has however, I believe, sufficient basis of fact and probability to justify my bringing it before you. Of the numerous hypotheses which have been brought forward to explain the influence of water in the production of goitre, the two which have received most support from observers on the subject, and which appear to have the broadest basis of the fact are (1) the theory that goitre follows the use of water from magnesian and limestone rocks, and (2) the theory that the presence of iron pyrites in the strata from which the water is drawn is the cause. I believe that in the coincidence of these two may be found the true explanation, or, to speak more accurately, that the presence of iron in the strata in a form liable to pass into a soluble salt of iron on meeting with the ordinary spring water of the district may account for the above discrepancies, and afford a rational explanation. I am quite aware of the objection to the above theory, that iron is very universally diffused and constantly occurs in water where no goitre is found. This would, however, apply with equal force to any of the other properties of water which have been suggested as the cause. Iron pyrites is insoluble, but when brought in contact with spring water containing carbonate of lime and magnesia in carbonic solution it gradually passes by a process of oxidation into carbonate of iron. This salt of iron is, according to Professor Ringer, most readily and directly assimilated by the system. Now, the mode in which the water tends to aggravate or promote goitre may possibly be as follows: Iron is in a certain sense food, and is necessary and conducive to the formation of the red corpuscles of the blood. Administration of iron in anæmia increases the number of the red blood-corpuscles and the amount of iron contained in them, and although such result may not take place in health, it is not too much to assume that a readily assimilated form of iron dissolved in minute quantities in water would act as food for and stimulate the production of the red corpuscles, and so throw more work upon the glands which deal with these corpuscles in the system. Now, the most recent view as to the physiological function of the thyroid appears to be that it is an excretory organ for the effete blood-corpuscles, and may it not be that the observed effect is the result of undue ingestion of that form of food with the excretion of which the gland is concerned? I use the word food advisedly, because I believe (assuming the theory to be correct) the result to be due not to the ingestion of large quantities of iron, but to the habitual and constant consumption of minute traces of iron in a most readily assimilable form, and which would pass into the system as albuminate of iron. The carbonate of iron indeed under such conditions in natural water would be constantly in a state of change, and would only exist in the water in small amount in ordinary circumstances, and imperceptible to taste, and being a most unstable compound it is readily precipitated. This is a reason why iron in this form is not unfrequently overlooked, as after the lapse of some time and a little exposure the iron is precipitated, and no reaction follows the tests for iron applied to water in ordinary sanitary analysis. The therapeutic effects of iron may throw some light upon this point. When iron is administered therapeutically, a sensation of fulness and pain in the head sometimes supervenes, and is recognised as indicating the desirability of discontinuing the medicine. This would give support to the theory advanced. On the other hand, anæmia is frequently present with goitre. This may be due to the blood-elaborating function of the thyroid being out of order; but iron is said, in some cases of anæmia accompanied with goitre, to produce marked benefit. I believe these cases will be found where a strumous and neurotic diathesis is the preponderating cause. In connexion with this subject, I think it well to refer to the instance so frequently quoted of French peasants, who are alleged, in order to avoid the conscription, to artificially produce goitre by drinking goitriferous water. According to the best account I can obtain, the conscripts are said to "go up to Briançon." Briançon is, I believe, upwards of four thousand feet above the sea, and this fact, combined with the goitrous diathesis of many Frenchmen, would be powerful contributing influences.

Is Goitre diminishing in England?—Endemic goitre certainly is. In a disease where the influence of heredity is so marked, we may assume that the endemic prevalence may to some extent in isolated communities have been due to intermarriage, and that increased migration and facilities for travel would certainly tend to produce a decrease; but I am persuaded that the chief cause is due to the disuse of the practice of carrying weights on the head. This would chiefly apply to those hilly districts where a slight contributing influence, in addition to that of diminished atmospheric pressure, is all that is needed to induce the deformity. Throughout England generally there has been, during the last quarter of a century, a marked alteration in the custom of the rural population in the matter of carrying weights. To carry weights on the head safely, and with comfort, requires early training and practice. Before the introduction of tins with handles, the wooden milk pails with side handles were of such a shape and make that when full they could not well be carried by one person except on the head. Hence the early training and acquired facility in carrying weights on the head. The introduction of tin ware with handles has altered this, and led to the disuse of the practice, and, as I believe, may thus be said to have contributed to the diminution of goitre in some agricultural districts in England. With sporadic goitre in towns the case may be different. This affection is said by some to be on the increase. If this be so, and, considering the element of debility present in so many of these cases, the neurotic influence may be the preponderating one, and the theory advanced by Dr. Woakes is probably correct—viz., that this affection shares in a general increase of neurotic affections in the present age.

Epidemic Goitre.—Time will not allow me to do more than to refer to the epidemic of goitre mentioned in the commencement of this paper. It had been noticed for some months before I investigated it, and the cause I believe to have been purely climatic, probably aggravated by some meteorological condition peculiar to the year.

Connexion of Goitre with Cretinism.—On the theory of goitre being a circulatory disease and dependent to a large extent on atmospheric influences, the connexion of cretinism with goitre seems to admit of explanation. In some countries the goitriferous influences, including the strumous diathesis, may be sufficient to produce goitre and cretinism in the same individual. In this country cretins are rare, and in the majority of such cases in which a post-mortem examination has been obtainable, the thyroid has been found absent. Now, assume an infant of a strumous diathesis with deficient arterial tone under strong goitriferous influences. In the absence of the safety valve action of the thyroid, a cretinous condition would be expected to result. Indeed, the converse may be true, and I have recently met with a microcephalic idiot with a huge goitre.

NOTES ON TWO CASES OF REMOVAL OF THE JAW FOR TUMOURS.

BY F. F. PERRY,

SURGEON, BENGAL MEDICAL SERVICE; LATE DEMONSTRATOR OF ANATOMY, WESTMINSTER HOSPITAL.

THE cases to which the notes below refer occurred during the present year and exhibit several points of interest.

CASE 1. *Large naso-pharyngeal polypus, removed by displacement of the superior maxilla.*—Badawah, Mahomedan, male, aged forty, was admitted into the Mayo Hospital, Lahore, on April 26th, 1884. His general health fairly good. Nothing noteworthy regarding his family, habits, &c. His present illness commenced three years ago, when he noticed some obstruction in his right nostril. Since then the obstruction has progressed gradually with swelling of the right cheek, difficulty in breathing and swallowing, and a moderate amount of pain. Urgent symptoms, connected with dyspnœa, dysphagia, and want of rest, have been present during the past three or four months, and lately he has lost much flesh.

Present state.—A thin and weakly-looking man, evidently considerably emaciated and with a marked look of distress; breathes with mouth wide open, and voice has a marked nasal twang. The right cheek is seen to be bulged outwards *en masse*, the outline of the bone not being interfered with. At the inner angle of the right eye is a soft swelling, the shape and size of an almond, which can be emptied of thick mucoid material into the nose by applying pressure over it. Both nostrils are completely blocked, the right by a soft reddish growth which extends to within a quarter of an inch of the orum nasi, and the left by the septum, which is pushed over in a very marked degree. On looking into the mouth the hard palate is seen to be natural, but the whole of the upper two-thirds of the pharynx is occupied by a rounded mass which pushes the soft palate down in front of it, so as to interfere considerably with respiration. Marked dysphagia is also present, and liquid food only can be taken. The diagnosis of naso-pharyngeal polypus of large size and probably high attachment was made. The patient's general condition was good, and he was very anxious for something to be done.

On April 28th chloroform gas was given by the mouth, but produced troublesome symptoms owing to pharyngeal obstruction. Tracheotomy was performed and the inhalation of chloroform carried on without further hitch through the tube. The right superior maxilla was then displaced in the ordinary way, the superficial incision being carried through the centre of the upper lip, along the side of the nose and lower margin of the orbit, and the flap turned downwards. The bone was then divided by saw and bone forceps and displaced outwards, the soft palate being separated transversely from the hard on the right side. An enormous soft reddish growth was found occupying the naso-pharyngeal and right nasal cavities, having three or four points of attachment to the under surface of the skull. The largest portion (about the size of a medium orange) was detached and removed with difficulty through the mouth. Various smaller pieces were torn off and withdrawn from in front and the stump freely cauterised with the hot iron. Throughout the operation there was remarkable freedom from hæmorrhage. The bone was then replaced and kept *in situ* by drilling the malar process and wiring it together with silver wire and connecting the incisor teeth in the same manner. The flap was sutured with alternating wire and catgut sutures, the soft palate being left untouched.

The man was placed in a separate ward, which was kept at a uniform temperature and carefully steamed at night. The tube was left in the trachea for the first twelve hours, and covered with a light bag of pine sawdust, purified with eucalyptol. At the end of this time it was removed, and a light bandage applied. Recovery was uninterrupted, and very rapid. The patient slept well and could take large quantities of liquid nourishment. Pulse of good quality, and the temperature never exceeded 100·5°. On the third day his condition was as follows:—Temperature 100°; pulse 90; wound entirely and soundly healed by first intention, with the exception of a small opening through the soft palate, and another at the point of exit of the wire through the malar bone; tracheal opening contracted to the size of a crowquill; moderate amount of inflammatory swelling about the right side of the face, but this rapidly disappeared. All the sutures were removed, and on the seventh day the man sat up in bed and ate soft solid food, being quite free from all symptoms of dyspnœa and dysphagia. The wire suture was removed on the tenth day, and in the following night he considered himself well enough to run away, a common practice with patients in this country. He was seen at work accidentally about a week afterwards.

Remarks.—The points of interest in connexion with this case are: 1. The large size of polypus. 2. The great help obtained during the operation by first performing tracheotomy. 3. The rapid recovery of the patient.

CASE 2. *Entire excision of the lower jaw for myeloid sarcoma.*—Mussamat Jhandi, a female Hindoo aged thirty-two, was admitted into Jullunder Dispensary on September 26th, 1884.

Her general health had been good; mother of several children, and is at present nursing one. Has had occasional attacks of intermittent fever, but not seriously. No history of syphilis. Her present illness commenced two years ago with a swelling about the central incisors of the lower jaw; very gradual at first, but much more rapid during the last three months. Has emaciated considerably of late, and especially since the protrusion of the growth between the lips (about two months). Can assign no cause, and has not had much pain, but suffers principally from the inconvenience arising from the position of the growth and the difficulty in masticating and speaking.

Present state.—A slightly made and much emaciated woman about thirty years of age. Temperature normal; pulse weak and small; respiration healthy. No disease present, with the exception of that in the lower jaw, which is the seat of a growth of a reddish colour, part of which protrudes between the lips. The protruded portion is the size of a large walnut, irregularly lobulated and ulcerated on the surface from constant exposure to air and dirt. The lips cannot be made to close over it. Internally the growth is found to involve the lower jaw, principally at its upper or dental margin, and to be of a soft, almost fungating nature, with the teeth embedded and lying quite loosely in it. The bone itself is felt to be considerably expanded in its upper half, the limits being on the right side beyond the last molar tooth, and on, up to, and including the first molar. The lower border of the bone is free, but behind the symphysis there is a nodule, about the shape and size of half a walnut, which appears to be springing from the bone. The whole growth is about the size of a small orange, and gives the jaw a peculiar pointed appearance. No enlargement of glands can be detected, nor are the superficial structures in any way involved. There is the greatest difficulty in eating anything, even liquids being taken with considerable effort, so that really the woman is being slowly starved. Speech is so much interfered with that her statement is made out with difficulty. She is extremely anxious for an operation to be performed.

She was kept quiet in hospital, and fed up as far as possible for twelve days, taking also small doses of quinine. During this time it was noticed that there was a decided increase in the size of the growth and its protrusion from the mouth.

Operation.—On Oct. 9th, under chloroform, laryngotomy was performed as a preliminary step in order to facilitate the main operation by obviating the risk of the respiration being impeded by the falling back of the tongue over the glottis, and also to facilitate the administration of chloroform. A ligature was then passed through the tip of the tongue, to retain command over it in case of any accident to the tube in the larynx. At this stage, owing to the failure of the heart's action, the pulse, which had been very bad throughout, ceased altogether, and artificial respiration had to be performed for about ten minutes and a brandy enema given. On the restoration of animation, the administration of chloroform was continued through the tube. No further trouble was experienced on this score, the breathing and pulse continuing good throughout the remaining steps of the operation. An incision was made on the right side from a point three-quarters of an inch below and half an inch in front of the external auditory meatus along the lower border of the jaw to the median line. The facial artery was controlled and ligatured before any hæmorrhage took place. The bone was then cleared by means of a blunt periosteal scraper, the knife being entirely laid aside, except to divide the mucous membrane and, carefully guarded, to touch the capsule of the joint from in front. One small muscular branch in the substance of the masseter had to be ligatured, but no large vessel was injured, and the bone was entirely and cleanly cleared. Detaching the temporal muscle from the coronoid process was found to be the most troublesome part of the operation. The same process was gone through on the left side, the facial line being twisted, and no ligature was necessary. The bone was removed in its entirety, and was quite free from soft parts, with the exception of a small portion of the insertion of the internal pterygoid on the left side. Not more than an ounce and a half of blood was lost during the whole operation, which occupied an hour and a half. An enormous wound, seven inches in length, resulted, which was carefully closed by ten metallic and sixteen catgut sutures, the edges being painted over with compound tincture of benzoin. The tube was left in the larynx and covered with a light pad of carbolised sawdust. The following arrangements were made:—1. A separate ward and special service of attendants. 2. The nights being unusually cold for the season of the year, and the difference between the day and night temperature being marked, care was taken to maintain an equable temperature by means of fires and steaming the room between the hours of 5 P.M. and 9 A.M. 3. The tube was constantly protected with a light pad of sawdust and muslin bandage, and cleaned out with a feather occasionally. At the end of twenty-four hours it was changed, and on the fourth day removed altogether, the patient continuing to breathe through the opening. 4. A pint of milk and half an ounce of brandy were given every eight hours, and an enema of soup (four ounces) with brandy (half an ounce) each afternoon. 5. A solution of morphia (one drachm) was given night and morning.

The woman did remarkably well from the first. There was no shock, and with the exception of a moderate amount of pain, principally in the head, she was fairly comfortable. She slept a good deal day and night and took all the nourishment ordered by her own efforts for the first thirty-six hours; but after that, owing to the presence of inflammatory swelling and the fixing of the tongue to the floor of the mouth, she was fed through a tube passed to the back of the pharynx. The wound united firmly throughout by first intention and half the sutures were removed on the third day and the remainder on the fourth, when her condition was as follows:—Temperature 100·5°; pulse 110; respiration 28. Breathing quietly, and can lie in any position with comfort, and sit up. Is suckling her baby, and has insisted in doing so since twenty-four hours after the operation. Asked for semi-solid food and is picking up strength and flesh very rapidly. Can articulate when the laryngeal opening is closed with the finger. Tongue clean and bowels regular. There is only moderate discharge from the interior of the mouth and no facial paralysis. On Oct. 14th, or six days after the operation, the temperature rose to 102·5° and the respiration to 35. Patient complained of pain in the right axilla, but nothing could be detected on examination. A mustard plaster was ordered and greater precautions were taken to avoid chill. However, symptoms of acute pleuro-pneumonia of right side developed themselves, and the patient died on the eighth day of exhaustion. No doubt the woman, considering herself out of danger, had thrown off her clothing during the early part of the night and had caught a chill in the early morning, when the difference in temperature was most marked. Post-mortem examination was not allowed.

Remarks.—As in the previous case, the opening of the larynx as a preliminary measure was of the utmost service during the performance of the operation itself, and almost a necessity afterwards owing to the tendency of the tongue to fall back on the glottis. The remarkable freedom from hæmorrhage, and the fact that the facial nerve on both sides was uninjured, I attribute entirely to the use of a blunt scraper instead of a knife. It is evident from the rapid progress of the patient towards recovery that the cause of death was accidental, and I think it may be claimed that the operation itself was successful. I made no objection to the mother suckling her child, so long as she took and assimilated such large quantities of nourishment, for it is a common occurrence in this country to continue suckling after the most severe operations and injuries. Examination of the tumour showed it to be a myeloid sarcoma springing from the central portion of the maxilla, and involving the dental margin. I am indebted to Surgeon-Major P. Ramsay for his able assistance during the operation.

CLINICAL STUDY OF THE LIVER VIEWED THROUGH THE URINE.

BY GEORGE OLIVER, M.D. LOND.

(Concluded from p. 884.)

The systemic diffusion of bile salts from the portal organs is apparently not excessive, but the kidneys fail to keep pace with it.—Hitherto I have dealt only with the reaction of the peptone test suggesting the presence of an increased quantity of the biliary salts in the urine; as in jaundice, diseases of the liver and spleen, fever, and in diseases in which the cellular elements of the blood undergo dissolution—such as some varieties of anæmia, scurvy, and hæmoglobinuria; the increase being absolute, even though the discharge of the biliary elements is at times lessened. Should any clinical value be attached to the renal elimination of bile salts when subnormal, or reduced to the verge of extinction? I am under the impression that a surcharge of these excreta in the blood may now and then take place from an imperfect removal of them by the kidneys, though there are no apparent indications of derangement or embarrassment of the portal organs to favour the accumulation. This is as yet, however, but little more than a surmise; and it may turn out that the detection of an excess of these biliary derivatives in the urine is the only important clinical aspect of the subject. A subnormal reaction is met with in many apparently healthy individuals, in whom perhaps the other emunctories, the skin and the bowels, are in this respect more active than usual, or in whom there is less biliary matter to be disposed of; also in a large proportion of those said to suffer from chronic biliousness, but who for their years probably make less bile than normal (subcholia), and in various forms of deficient constructive activity, as in ordinary anæmia and the like.

Chronic renal disease.—I have been rather struck with the fact that in all the cases of cirrhotic kidney I have examined the reaction was either decidedly subnormal or *nil*. But in a case of waxy kidney, which I observed from its origin to its close, the reaction was always above normal —often considerably so—and the post-mortem examination afforded no indications of uræmic poisoning, nor were any observed during life.[1] If this observation be confirmed by further inquiry, perhaps the question will arise how far should the symptoms of uræmia be referable to the grave form of cholæmia that culminates in convulsions and coma?

Skin disease.—So far I have always found the reaction subnormal in eczema. This is the urine of a patient now under observation, and the reduction amounts to at least one-half.

Conditions that influence the renal elimination of the biliary salts.—I think it is highly probable that neurotic influences frequently play a leading part in checking the discharge of these excreta by the kidneys; they are, however, often obscure and difficult to track. Hence the teaching value of experimental evidence, such as that lately brought forward by M. Vulpian, who applied electric stimulation to the white matter in the neighbourhood of the sigmoid gyrus, and on inserting cannulæ into the bile-duct and urethra found the flow of bile increased and that of the urine arrested, and the animal was seized with epileptic convulsions. This observation is probably of clinical interest in suggesting how a source of eccentric irritation—such as an undigested mass lodging in the stomach—may take the part of the electric current of the experiment and induce like effects. Then, again, some medicines increase the renal elimination of bile salts, while others appear to check it. The experiments of Feltz and Ritter showed that the preparations of antimony and arsenic augment the bile salts of the blood and the urine; and the mode of death in chronic poisoning by these metals is similar to that induced by the biliary salts—namely, cardiac asthenia and fatty degeneration. On the other hand, opium is probably a checking agent; and this remedy *administered alone* is, as a rule, a sort of touchstone with the cholæmic. If this be so, the clinical acumen of Graves, who *prescribed antimony* along with opium in the cerebral excitement of fever, shot ahead of experimental inquiry; and perhaps other corrective combinations, such as Dover's powder, which have received the sanction of experience, may be shown to rest on a basis of fact which accounts for their *raison d'être*.

---

[1] Just at this time I have under observation a young lady, aged twenty-one, suffering from intermittent albuminuria of hepatic origin, in whom I have noted the interesting fact that when there *is not a trace* of albumen (as is always the case in the urine discharged before breakfast) the amount of the bile salts as indicated by the peptone test merely reaches the normal standard; but when albumen appears (as it is apt to do in considerable quantity three or four hours after a meal) the proportion of the biliary elements rises considerably, becoming doubled or even trebled, and this at a time when they should appear in smaller quantity than in the morning. When after a meal there is no albumen, the bile salts are found in subnormal amount.

The degenerations of the cholæmic.—I am disposed to conclude that fatty degeneration is a prominent pathological feature of cholæmia. This position was well illustrated by the post-mortem examination of a patient whom I recently saw in consultation with Dr. Johnson of Kirkby Overblow. Within a period of four months a woman, aged fifty, became extremely anæmic without obvious cause, and without presenting any distinctive indications of organic disease; a positive sign of mischief was, however, afforded by the urine, which, though generally rather high coloured, gave no reactions of bile pigment, but, according to the peptone test, always contained a large quantity of bile salts—never less than 300 per cent. increase. The post-mortem examination, however, did not reveal the cause of the anæmia; it merely indicated the existence of widespread and advanced fatty degeneration—e.g., of heart, liver, &c. The amount of blood was remarkably small, and no clots were observable. I obtained about half a teaspoonful from the chambers of the heart, and on submitting it to microscopic examination I readily detected numerous molecules of fat, varying in size from that of mere granules to the dimensions of the largest oil globules found in milk. This observation of the fattiness of the blood was corroborated by several medical friends. The corpuscles were mostly leucocytes.[2] In four days the cellular elements had almost entirely disappeared, and the oil globules were much more numerous.

May not the continued discharge of an excess of bile salts by the kidneys favour or lead to the development of chronic renal disease?—I have no facts to adduce in favour of this suspicion, and I can merely point to the parenchymatous degeneration of the kidneys induced in animals by the intravenous and subcutaneous injection of bile salts, as recorded by Leyden, Feltz, Ritter, and Brown; and to the interstitial renal changes observed in leucocythæmia and in chronic jaundice. In this connexion, perhaps, I should note that Nothnagel believes that renal tube casts are always to be found in the urine of jaundice when bile acids are eliminated by the kidneys, and that Dr. George Harley has observed both hyaline and granular casts in the form of albuminuria which he denominates "hepatic."

When this paper was sent to press I proposed to append to it an addendum, consisting of notes of some recent observations on decoctions of liver, spleen, mesenteric glands, &c.; but other work just now compels me to defer the publication of these data, which, however, merely form the basis of further inquiry to be resumed next winter.

---

[2] The small number of red discs, and these considerably deformed, was remarkable. Were they in great part dissolved during the thirty hours that intervened between death and the post-mortem inspection? I think it is quite possible, if not probable, that such an event may happen after death in the cholæmic, just as it has been observed to occur [illegible] in hæmoglobinuric urine after emission.

THE statue of Pinel, given to the municipality of Paris by the Société Médico-Psychologique, and which has been placed in the Place de la Salpêtrière, will, it is stated, be formally unveiled on the 13th prox.

A CASE OF CONVULSIONS DURING PREGNANCY TREATED BY INJECTIONS OF PILOCARPINE; RECOVERY.

BY P. HORROCKS, M.D. LOND., B.Sc., M.R.C.P.
